# THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

## ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

VOLUME XXVI.

FROM NOVEMBER 7, 1890, TO MAY 1, 1891.

(RECAP)

LONDON:
Printed and Published for the Proprietors by GEORGE TUCKER, at the Offices of "THE ELECTRICIAN," Salisbury-court, Fleet-street, E.C.

1891.

Digitized by Google

# INDEX TO "THE ELECTRICIAN."

# VOL. XXVI.

## General Alphabetical Index.

### A

Aberdeen, 687.
Accumulator, Traction, 563, 659.
Accumulators, see Secondary Batteries.
Accumulators, A Charge Indicator for, 98.
Accumulators, High Discharge, 161.
Acid-resisting Varnish, 778.
Acquisition of the Telegraphs by the United States Governments 317.
ADDENBROOKE, G. L.
  Transformer Distribution, 599, 642.
Adelaide, 596.
Aden-Bombay Cable, Triplicate, 563.
African Cables, 687.
Agitation, The Telegraph in Times of, 594.
Agreements between Supply Companies and their Customers, 95.
Air Resistance at High Speeds, 162.
Alkaline Accumulator, 195.
Alternate Current Electric Mining Plant, 689.
Alternate Current Instruments, Some Practical Methods for the Determination of Inductive Resistances and Self Induction of: by Chas. Steinmetz, 79.
Alternate Currents through Concentric Cables, On the Propagation of: by Dr. J. A. Fleming, 258.
Alternate Current Condensers, 192.
Alternate Current Condensers: by Jas. Swinburne, 214, 260.
Alternating Current, Rectifying, 779.
Alternating Current Influence Machines: by James Wimshurst, 764.
Alternating Currents of Very High Frequency, Phenomena of: by Nikola Tesla, 549.
Alternating Currents of Very High Frequency, Notes on: by Prof. Elihu Thomson, 615.
Alternating Currents and Mathematics, 298.
Alternating Electric Arc between a Ball and a Point: by Ed. L. Nichols, 412, 429.
Alternating Electromotive Forces, The Striking Distances of: by Robert Shand, 518.

**Alternators—**
  Kingdon Inductor, 610.
  Westinghouse Arc Light, 20.
Alternators, The Coupling of, 394.
Aluminium Alloys, New, 288.
Aluminium, Electro Deposition of, 194, 778.
Aluminium Fluoride, Analysis of: by Adolphe Minet, 87.
Aluminium in the Electric Arts, 4.
Aluminium, Properties of, 661.
Aluminium Trolley Wheels, 162.
"Amber," The, 595.

**American Notes**, 20, 117, 155, 180, 216, 245, 278, 312, 339, 404, 433, 463, 495, 553, 585, 619, 651, 680, 709, 739, 767, 798.
American Patent System, A Century of the, 474.
Amsterdam, 778.
ANSELL, HAROLD W.
  Capacity of Submarine Cables, 168.
Antwerp, 3, 64, 688.
Arc and Incandescent Street Lighting in Paris, 319.
Arc (Electric) and its Use in Lighting: by Elihu Thomson, 562, 577.
Arc, Flow of Current through an Electric, 565.

**Arc Lamps—**
  Henderson Multiple Carbon, 352.
  Japy-Helmer, 470.
  Patin Alternate Current, 496.
Arc Lamps, Candle Power Classification of, 64.
Arc Lighting in the States, 321.
Arc Lights and Insects, 288.
Arc Lights, Some Remarks on Herr H. Luggins' Work on the Mode of Conduction in: by F. Uppenborn, 767.
Armature Cores, Graphic Method for Analysing Losses in, 700.
Armature Reaction, 531.
Aron Meter, 129.
Artificial Light of the Future: by Prof. Edward L. Nichols, 147.
Athens, Electric Light Station, 503, 718.
Atlantic Cable, the Laying of the First, 29.
Atlas Accumulator, 484.

**Australian Notes**, 405, 495.
Australian Cable Rates, 97, 474, 719, 728.
Austrian Telegraph Statistics, 751.
Automatic Temperature Compensation for Voltmeters, 128.
AYRTON, Prof. W. E.
  Measurement of the Power given by any Electric Current to any Circuit, 736.
  Notes on the Chemistry of Secondary Cells, 102, 127, 140, 176, 191, 215.
  On the Rise of Potential Difference in the Deptford Mains, 260.
  Proof of the Generality of Certain Formulæ published for a Special Case, by Mr. Blakesley. Tests of a Transformer, 540.

### B

BAILEY, F.
  Electric Lighting Progress in London, 159, 206.
Bale, 3.
Barking Road Line, 193, 286, 471, 562.
Barnsley, 129, 505.
BARR, PROF.
  On the Use of the Lantern in Class Room Work, 105.
Bath, 63, 445, 717, 752.

**Batteries (Primary)—**
  Hellsen Dry, 419.
  Messerole Dry, 226.
  Perrier-Lloyd, 352.

**Batteries (Secondary)—**
  Atlas, 484.
  Electric Storage Battery Company's Accumulator, 5.
  Experimental Storage Cell, 506.
  James, 751.
  Reynier Elastic, 113.
  Tommasi, 130.
  Woodward, 351.
Bavaria and Wurtemburg, Telephone Extensions in, 630.
Beacons, Electric Light, 162.
BELL, DR. LOUIS.
  Report of the Committee on the Proper Classification of the Lighting Power of Incandescent Lamps, 682.
Belting, 564.
Belts, Tight, 453.
Berlin, Electric Lighting of, 353, 444, 778.
Berlin, Proposed Exhibition at, 717.
Berlin, Telephone in, 286.
Berlin-Vienna Telephone Trunk Wire, 631.
Bernados Welding Process, 161.
Bibliography of Recent English Electrical Literature, 194.
BIDWELL, SHELFORD.
  Some Experiments with Selenium Cells, 213.
Bills of the Session, Electrical, 446, 473, 503, 717, 751.
Birmingham, Electrical Inspector for, 503.
Birmingham Electric Lighting, 751.
Blakesley's Method of Measuring Power, 529.
BLAKESLEY, T. H.
  Further Contributions to Dynamometry, 541.
  The Solution of a Geometrical Problem in Magnetism, 170.
Blast Furnace Use, Magnet for, 225.
Blasting, Electric, 564.
Board of Trade and the Protection of Telephones, 629.
Board of Trade Overhead Wire Regulations, 95, 112.
Board of Trade Rules, More, 424.
Board of Trade Unit, 563.
Boiler Competitions, 476.
Boiler Waters, An Indicator of Acidity in, 476.
Bombay, 63.
Boston Street Railway Power Station, 4, 717.
Boy Messengers and the Postmaster General, 562, 593, 751.
BOYS, C. V.
  On the Measurement of Electromagnetic Radiation, 286, 302, 335.
Bradford Municipal Station, 413.
Bremen, 194, 688.
Bridge Method when used for Periodic Currents, Lord Rayleigh on the Sensitiveness of, 777.
Brighton, 2, 352, 503, 687.
Brighton Grand Hotel, Electric Lighting of, 474.
Bristol, 129, 193, 583, 386, 631, 717.
British Association Meeting at Cardiff, 501.
British Guiana Cable, 96, 129.
British Museum, Electric Lighting of, 657, 685.
Bromley Local Board, 3, 28.
Brush Double Carbon Arc Lamp Patent, 318.
Buckingham Electric Light and Power Company, 253.
Buda Pesth Electric Tramway System, 169.
Buda Pesth, Telegraph and Telephone Wires in, 530.
Buffalo (N.Y.), Electric Railroading at, 64, 475.
Bunsen Photometer, Mr. Boulouch on the Theory of, 224.
Burmah, Telegraphic Extension in Upper, 779.

### C

Cable and Land Line Repairs, 688, 778.
Cable Cores, Testing the Centrality of: by Paul Le Goaziou, 80.
Cable Extensions, 97, 161, 194, 351, 444, 564, 778.
Cable Rates, Australian, 97, 563.
Cables, On the Determination of the Capacity of Long Submarine: by Arthur Dearlove, 537, 658.
Calais, Electric Transmission of Power at, 31.
Calais Submarine Cable Works, 161.
Calcutta-Bombay Telegraph Line, 27, 473, 631.
Cambridge, 287, 752.
Cambridge, Engineering at, 668.
Cambridge, Professorship of Mechanics at, 30, 351.
Canadian Government Telegraph and Signal Service, 52.
Canada, Proposed International Exhibition in, 29.
Candle-power Classification of Arc Lamps, 64.
Capacity and Self-Induction in Alternate Current Working: by Gisbert Kapp, 197, 229.
Carpenter-Nevens Electric Car Heater, 226.
Cars on Heavy Gradients, Electrical, 162.
Cataphoric Medication, 629.
Celluloid Covered Wire, 473.
Cement for Leather Belts, 778.
Census Counter, Electrical, 225.
Centesimal Method of Measuring Angles, 630.
Centimetre to Inch, Ratio of, 687.
Central Institution, 287, 778.
Central Lighting Station as an Investment, 195.
Central Lighting Stations of the United Kingdom, 274.
Central London Railway, 62, 353, 561, 564.
Central Station Lighting, Miniature, 287.
Central Stations of the Metropolitan Electric Supply Company: by Dr. J. A. Fleming, 9, 69, 107, 129.
Central Station Supply—Isolated Plants, 777.
Central Station, The most favourable Position for an Electric Light: by Dr. A. Föppl, 88.
Central Station Statistics, The Interchange of, 106.
Charge Indicator for Accumulators, 98.
Charging Stations for Thames Launches, 687.
"Chattering" on Overhead Circuits, Diminution of, 595.
Chelmsford, Electric Lighting of, 129, 287, 444.
Chelsea Electricity Supply Company and its Customers, 159, 163, 223, 226.
Chelsea Overhead and Underground Wires, 594.
Chelsea System, 383.
Chelsea Vestry, 532.
Chemical Society, 413, 504.
Chemical Union, Operations and Electrolytic Methods of Bleaching, 27.
Chemistry of Secondary Cells, Notes on the: by Prof W. E. Ayrton, C. G. Lamb, and E. W. Smith, 102, 127, 140, 176, 191, 215.
Chemical Elements, On certain Relations existing among the Refractive Indices of: by Rev. T Pelham Dale, 112.
Chemnitz, 2.
Chicago Exhibition, 65, 252, 319, 321, 501, 511, 751.
Chlorine, Action of Silent Discharge on, 447.
Chloro-Chromic Acid Battery, A Useful Application of, 531.
Choking Coils and Condensers in Connection with Constant Current Work, The Employment of, 750.
City and Guilds of London Institute, 98, 131.
City and South London Railway, 9, 12, 28, 97, 101, 129, 191, 285, 287, 317, 352, 385, 446, 504, 594, 631, 688.
City of London Electric Lighting (Pioneer) Company, 443.
City Notes, 25, 59, 93, 125, 157, 189, 221, 249, 283, 315, 347, 381, 409, 441, 469, 499, 527, 559, 591, 627, 655, 683, 713, 747, 805.
City, The Lighting of the, 193, 411, 415, 454, 505, 563, 632.
Civil Engineers, Institution of, 129, 254, 287, 317, 319, 530.
Coal Consumption, Curious Case of Increased, 751.
Coal Mines, Electricity in American, 194.
Coast Defence, Electric Light for, 687.
Coast Telegraphic Communication, 631.
Coffin Electric Welding System, 3.
Collection of Electrical Data, 27.
Colliery Lighting, 288, 473.
Cologne, 779.
Commutator, Davis and Stokes' Safety 630, 717.

**COMPANIES' MEETINGS, REPORTS, DIVIDENDS, &c.**

(Abbreviations:—Div., Dividend; Mtg., Meetings of Shareholders; Rev., Revenue; Rpt., Reports of Directors.)

African Direct Telegraph Company—249.
Allchin, Linnell and Co.—249, 381.
Anglo-American Telegraph Company—Rpt., 380; Div., 381, 747; Mtg., 437.
Anglo-Portuguese Telephone Company—249.
Austrian Electrical Company—315.
Bell's Asbestos Company—Div., 469; Mtg., 527.
Blackpool Electric Tramway Company—Mtg., 125.
Brazilian Submarine Telegraph Company—Rev., 25, 59, 93, 125, 157, 189, 221, 249, 283, 315, 347, 381, 409, 441, 469, 499, 527, 559, 591, 627, 655, 683, 713, 747, 775; Div., 157; Rpt., 804.
Brighton and Hove Electric Light Company—Rpt., 627; Mtg., 653.
British Insulated Wire Company—25.
British Tanning Company—Mtg., 590, 683.
Brush Electrical Engineering Company—771; Div. 527.
Cadogan Electric Light Company—Mtg., 591.
City of London Electric Lighting (Pioneer) Company—469.
City and South London Railway Company—Rev., 315, 347, 381, 409, 441, 469, 499, 527, 559, 591, 627, 655, 683, 713, 747, 775, 805; Rpt., 467; Mtg., 439, 522.
Commercial Cable Company—881; Div., 157, 591.
Continental Metropolitan Tramways Company, 805.
Cowle's Syndicate—Mtg., 249, 805.
Crompton and Co., Div. 221.
Cuba and Submarine Telegraph Company—Rev., 25, 157, 315, 469, 559, 683; Div., 409; Rpt., 441; Mtg., 467.
Direct Spanish Telegraph Company—Rev., 25, 189, 315, 441; Div., 559; Rpt., 591.
Direct United States Cable Company—Div., 315, 747; Rpt., 347; Mtg., 349, 623; Rev., 713.
Eastern and South African Telegraph Company—25, 93, 221, 381.
Eastern Telegraph Company—347, 381, 591, 775; Rev., 25, 157, 315, 441 559, 713; Div., 221; Mtg., 343, 348.
Eastern Extension Telegraph Company—Rev., 25, 157, 315, 441, 559; Mtg., 92, 772; Div., 221, 713; Rpt., 745.
Edison and Swan United Electric Light Company—Div., 469.
Electric Construction Corporation—347, 559; Div., 93; Rpt., 124; Mtg., 185.
Electrical Automatic Delivery Box Company—249.
Electricity Supply Company for Spain—409.
Elmore's Foreign and Colonial Copper Depositing Company—249, 655, 682; Mtg., 282, 407, 711, 804; Div., 409.
Elmore's French Patent Copper Depositing Company—315; Mtg., 345.
Elmore's Austro-Hungarian Company—713; Mtg., 381, 408.
Excelsior Copper Company—Mtg., 249, 315.
Foreign Electric Date and Time Stamp Company—713.
Foreign and Colonial Elmore Patent Copper Depositing Company—Div., 93.
Fowler-Waring Cables Company—Mtg., 157, 185.
General Austrian Electricity Company, 381.
Globe Telegraph and Trust Company—Div., 347, 713.
Great Northern Telegraph Company—Rev., 25, 157, 315, 469, 591, 713; Div., 221, 747.
Greenwood and Batley—Div., 221.
Gulcher (New) Electric Light and Power Company—Rpt., 189; Mtg., 219.
Hastings and St. Leonard's-on-Sea Electric Light Company—Mtg., 468.
Henley's Electric Light and Power Company—Mtg., 249.
Henley's Telegraph Works—Mtg., 249, 283.
Hornsby and Sons, R.—Div., 93, 189.
Hoster, Albert—315.
Hoster di St. Nicolas, Ateliers—315.
India Rubber, Gutta Percha and Telegraph Works Company—Rpt., 469; Mtg., 498.
Indo-European Telegraph Company—Mtg., 800.
International Okonite Company—Div., 315.
Kelvinside Electricity Company—59.
Keswick Electric Light Company—Rpt., 526.
Libiolia Copper Company—Mtg., 591.
Liverpool Electric Supply Company—Mtg., 525.
Liverpool Overhead Railway Company—Mtg., 469.
London Electric Supply Corporation—Rpt., 589; Mtg., 621.
London Platino Brazilian Telegraph Company—527; Div., 775.
Manchester Edison-Swan Company—Mtg., 526.
Manganese Bronze and Brass Company—Div., 381.
Manitoba Electric and Gas Light Company—Div., 249.
Maxim-Weston Electric Company—Mtg., 381.
Metropolitan Electric Supply Company—Rpt., 24, 775; Mtg., 56, 801.
Middlesborough (U.S.A.) Electric Light, Heat and Power Company—25.
Montevideo Telephone Company—Mtg., 22.
Montevidean and Brazilian Telegraph Company—59; Mtg., 120, 184.
Muntz Metal Company—Div., 527.
National Telephone Company—Div., 189; Mtg., 376; Rev., 559.
New Shanghai Electric Company—Rpt., 747.
New York Belting and Packing Company—Mtg., 655, 713, 746.
Oriental Telephone Company—805; Div., 591; Rpt. 712; Mtg., 744.
Vetzold and Co.—747.
Phonopore Syndicate—Mtg., 249.
Poole and White—Mtg., 712.
Portrush Electric Tramway Company—Mtg., 499.

**COMPANIES' MEETINGS, &c.** (*continued*)—

Portsmouth and South Hants Electricity Supply Company—Mtg., 315.
Reuter's Telegraph Company—747; Mtg., 124, 188, 248, 803; Rpt., 774.
Ruston, Proctor and Co.—25.
St. James' and Pall Mall Electric Light Company—347, 713; Mtg., 524, 558.
Sanitas Company—527; Div., 529.
Simonds' Steel and Iron Forging Company 221.
Societe Anonyme d'Electricite Industrielle—527.
South of England Telephone Company—Mtg., 589, 625, 745, 774.
Spiet's Petroleum Engine Company—Mtg., 283.
Stock Exchange—25, 93, 125, 189, 283, 381, 527, 655, 805.
Submarine Cables Trust, 683; Rpt., 804.
Swan United Electric Light Company—Div., 59, 805; Rpt., 93; Mtg., 122.
Taunton, Delmard, Lane & Co.—93.
Taunton Electric Lighting Company—627; Rpt., 527; Mtg., 558.
Telegraph Construction and Maintenance Company—Div., 469; Rpt., 526; Mtg., 558.
Telephone Company of Austria—Div., 655.
Telephone Company of Egypt—Rpt., 627, 655.
United Asbestos Company—Mtg., 627.
United River Plate Telephone Company—221.
Venezuela Telephone and Electrical Appliances Company—Div., 347, 441.
Wenham Lamp Company—Div., 93.
West African Telegraph Company—527; Div., 249.
West Coast of America Telegraph Company—221, 775; Rev., 25, 157, 315, 469, 627.
West India and Panama Telegraph Company—Rpt., 24; Rev., 25, 93, 157, 315, 381, 441, 527, 558, 627, 713; Mtg., 56; Div., 775.
Western and Brazilian Telegraph Company—Rpt., 24; Rev., 25, 59, 93, 125, 157, 189, 221, 249, 283, 315, 347, 381, 409, 441, 469, 499, 527, 559, 591, 627, 655, 683, 713, 747, 775, 805; Div., 771.
Western Counties and South Wales Telephone Company—Mtg., 220.
Western Union Telegraph Company—409.
Westinghouse Electric Company—283.
Westminster Electric Supply Corporation—469; Mtg., 22, 524; Rpt., 498.
White's Asbestos Company—Mtg., 283, 381.
Woodhouse and Rawson United—499; Mtg., 314, 343; Div., 441.

**COMPANIES (NEW) REGISTERED**—

*The following Companies have been Registered under the Limited Liability Acts.*

Alice Street Foundry, 249.
Anglo-American Saw Mills Company, 125.
Aspinall's Enamel, 591.
Avon India Rubber Company, 249.
Birmingham Telegraph Factory, 314.
Brill Brick and Tile Company, 775.
British Hydraulic Company, 747.
Brown's Metallic Packing Company, 747.
Burgess and Co., 591.
Carbon Electric, 775.
Chagford and Devon Electric Light Company, 125.
City of London Electric Lighting (Pioneer) Company, 499.
Collier Audible Telephone Syndicate, 775.
Corifact Syndicate, 804.
Cuttriss, Wallis and Co., 804.
Dermatine Company, 683.
Donald (John), 283.
Edinburgh and Leith Safe Deposit Company, 683.
Electric Stores, 249.
Electrical Supplies and Fittings Company, 59.
*Electricity* and *Electrical Engineering* Newspaper Company, 125.
Electrolytic Syndicate, 125.
Evans, J. H. and Co., 25.
Farnshaw and Sons, 747.
Financial Exchange and Bureau, 125.
Foreign Electric Date and Time Stamp, 221.
Froude Hurrell Torpedo Company, 713.
Glass and Metal Engineering Company, 221.
Hindle (Robt.) and Co., 747.
Horsham Ironworks, 157.
International Electric Syndicate, 775.
Jarrow Forge and Engineering Company, 655.
Johnson, Mattey and Company, 747.
Kidd (J.) and Son, 249.
Lactite, 249.
Langness Copper Company, 683.
Leeds Copper Company, 409.
Liverpool and District Pulsion Telephone Company, 627.
London Electrical Tramways Company, 804.
London Metallurgical Company, 221.
London Rubber and Packing Company, 683.
Marine and General Automatic Company, 189.
Mathieson (Alexr.) and Son, 655.
Mazapil Copper Company, 527.
Mobbs and Co., 591.
Moss Bay Hematite Iron and Steel Company, 747.
New York Belting and Packing Company, 221.
New Zealand Electrical Syndicate, 283.
North-Eastern Telephone Company, 381.
Plenty and Son, 189.
Practical Electro-plating and Enamelling Co., 249.
Priest (John) and Son, 627.
Purdon-Walters Motor Syndicate, 249.
Richmond (Joseph) and Co., 559.
Rubber Trust Syndicate, 559.
Sampan Patent Railway Sleeper and Steel Plant Syndicate, 283.
Scott (Ernest) and Mountain, 125.
Shettleston Oil and Chemical Company, 221.
Shropshire Electric Light and Power Company, 469.
Sleeman Controlled Torpedo Syndicate, 157.
Societe Anonyme d'Electricite Industrielle, 527.
Societe D'Eclairage Electrique de Cannes, 499.
South Indian Railway Company, 157.

**COMPANIES (NEW) REGISTERED** (*continued*)

South Moulton Shirt and Collar Manufacturing Company, 189.
Southern Railway of Peru, 315.
Staffordshire Chemical Company, 747.
Steam Loop Company, 189.
Tewkesbury Agricultural and General Engineering Company, 469.
Tylor and Sons, 221.
Union Engineering Company, 747.
United Alkali Company 25.
United States Power Syndicate, 591.
Weybridge Electric Supply Company, 713.
Weymersch Electric Battery Syndicate, 157.
Companies' Share List, 26, 60, 94, 126, 158, 190, 222, 250, 284, 316, 348, 382, 410, 442, 470, 500, 528, 560, 592, 628, 656, 684, 714, 748, 776, 806.
Comparative cost of Arc and Sunbeam Lamps, 780.
Concentric Cables, On the Propagation of Alternating Currents through, by Dr. J. A. Fleming, 258.
Condenser introduced into an Alternate Current Circuit, The Effect of a: by Dr. Oliver Lodge, 762.
Conductivity of Stranded Wires, 412.
Conductivity under Different Electrical Influences, Variations of, 161.

# THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

## ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 651.—Vol. XXVI. FRIDAY, NOVEMBER 7, 1890. Price Fourpence.

## NOTES.

Some useful suggestions with regard to the measurement of resistance have recently been made by M. Chaperon, who, in three short Papers appearing in the October number of the *Journal de Physique*, discusses the capabilities of the Wheatstone's bridge method when a telephone and alternate currents are used in place of the ordinary galvanometer and battery. In spite of the great delicacy of the telephone, measurements made with it are much less accurate than those obtained with a reflecting galvanometer, because the adjustment for minimum sound is never sharply defined. This is, to a great extent, due to the fact that all resistance coils obtainable have a certain amount of self-induction, and produce a considerable inductive effect with alternating currents of the high frequency occurring in the telephone. If this disadvantage could be overcome, the telephone would, in many cases, be a more sensitive and convenient instrument to employ than the galvanometer; and it is in this connection that M. Chaperon's suggestions are of value. The experiments have been more particularly directed to the improvement of the Kohlrausch method of measuring liquid resistances. To reduce the polarisation effects to a minimum, and to render heating negligible, M. Chaperon arranges each branch of the bridge so as to have a high resistance of about a thousand ohms. The stretched platinum iridium wire is very thin, only about ·02 millimetres in diameter, and, in order that the fixed resistance may have no great inductive effect, a special system of winding has been adopted.

The ordinary method of double-winding used in resistance coils serves very well for most direct current measurements; but the compensation for induction effects is not nearly perfect enough when rapidly alternating-currents are used, and according to M. Chaperon, the results obtained under such circumstances are "detestable." The new coils have been wound singly, but so that successive layers are wound in opposite directions, the operation being effected by a specially constructed machine. The current in adjacent conductors thus flows in opposite directions, and self-induction is practically eliminated, while the capacity effect is rendered negligible since contiguous portions of the wire are at nearly the same potential.

This method has already been used by Mr. Swinburne in the construction of non-inductive resistances for wattmeters. The chief object in view in this case was to secure good insulation by keeping the ends of the coil well apart; and the mode of winding, which is described in the Paper on "Testing Iron" in our issue of October 10th, consisted simply of reversing the bobbin in the lathe on the completion of each layer. This method is stated to yield as good non-inductive coils as the ordinary method of double winding, while the strength of the insulation is much increased.

An interesting instance of the way in which the advancement of practical knowledge contributes to the progress of theory is afforded by an artifice adopted by M. Chaperon, and which appears to have been attended with excellent results. The telephone used had a resistance lying between 150 and 200 ohms, and was thus unsuited to a Wheatstone bridge, the resistances in which were many thousands of ohms. This difficulty was, however, entirely overcome by using a small transformer, the primary circuit of which had a resistance of 5,000 ohms, and placing the telephone in the secondary circuit.

The Wenstrom hydraulic gear for electrical traction, which is alluded to by our New York correspondent, is an ingenious clutch for gradually starting a car while the armature is running at full speed. The device consists of a rotary pump full of oil, the intake and delivery ports being connected by a short passage, in which there is a plug valve. The pump is of the well-known Beale's exhauster type, which is, perhaps, better known to our readers in the modification to be found in the air blower of the Thomson-Houston dynamo. It consists of a cylindrical block placed eccentrically in a chamber, which is divided into two parts by a pair of shutters sliding in a groove in the block. When the valve is open the armature runs idle, the oil merely circulating. When the passage is closed the pump is locked, since the oil is incompressible. By partially closing the valve the speed of the car may be controlled without proportionally reducing the velocity of the armature. It seems that this invention —which aims at being nothing more than a friction clutch, and, as far as it goes, achieves a very useful purpose—just misses a far more important result, namely that of a variable speed gear. The idea occurred to us, when the Rigg hydraulic engine was first described, that two such engines coupled together in series hydraulically would form such a gear. The eccentricity of this engine, it will be remembered, is variable. A short stroke hydraulic motor pumping into a long stroke motor is what is wanted for electrical purposes. When running idle the stroke of the hydraulic motor should be nil, at starting

Digitized by Google

it should be small, and at full speed of the car it should be a maximum. Now then, inventors, there is the idea! In Reauleaux's "Kinematics of Machinery" there are between fifty and sixty "chamber crank trains," from which hints may be gathered for putting it into practice.

The regulation of motors for electric traction is a problem which seems to offer a fascinating field for the efforts of inventors. Some would use a single motor, pointing out, with good reason, that large machines are obviously more efficient than those of smaller dimensions. To this it is answered that when the two are fully loaded, the actual amount wasted electrically on account of this decreased efficiency; and mechanically, by reason of the more numerous bearings—not to say economically, in view of the multiplication of parts—is trifling compared with the facilities which are offered when an extra pull is required at starting, or when a comparatively small amount of power is needed when the car is lightly loaded, or when it is running down a gradient. A common practice is to interpose a resistance on starting, to prevent the rush of current through the stationary armature; and when, for the sake of claiming an advantage over a rival system rather than for obtaining any economic advantage, the necessary coils are wound round the magnet bars which are presumably furnished already with their proper windings, the system is said to offer a peculiar superiority, in that it employs no rheostat. Others will boldly put their resistance coils on slate frames and use asbestos without any apology, and great ingenuity has been expended in utilising a minimum number of coils in a maximum number of combinations.

If there be a form of lift which offers absolute safety it is probably to be found in that kind which is provided with a long vertical screw, the cage being attached to a massive nut. The friction which such a device entails has allowed the hydraulic lift to put this mechanical arrangement into the background. But with the application of electric motors in view, Mr. C. A. Lieb has invented a most extraordinary ball bearing. According to a sectional view of this bearing in the *Electrical World* of New York of Nov. 1st, the nut, for a length of nine threads, does not bear directly on the screw, but a continuous row of steel balls is interposed. As the screw turns the balls must evidently travel along relatively to the nut at half the velocity of the helix of contact; but whither can they travel? Mr. Lieb, in reply, provides a tunnel through the nut parallel to its axis, and through this a procession of balls makes its way from one end back to the starting point. Whether this remarkable application of the ball-bearing principle, which has done so much for the bicycle, will extend the field of usefulness of the electric motor, remains to be seen; the ingenuity of the idea is most remarkable.

Amongst the disputed points in the subject of electrical discharges is the phenomenon of globular lightning. Many treat this as an optical illusion due to the excessively minute duration of the spark discharge, just as, when we have for an instant gazed upon the noonday sun and turn away, we see a reddish globe of fire float slowly straight before our eyes. So singularly do the descriptions of globular lightning tally with this well-known phenomenon, that this explanation would be irresistible were it not for the fact that these portentous spheres are alleged to terminate their alarming promenades by a deafening explosion. On the other hand, it is impossible to explain away the many records of persons who have seen the slowly-moving globes of fire. Amongst these persons was the electrician Cavallo, who saw a luminous ball slowly ascend the stem of a Leyden jar, then slowly descend and burst with a loud report. At a recent meeting of the *Académie des Sciences*, at the conclusion of a Paper on this topic by M. Faye, the meteorologist, the ex-Emperor of Brazil, narrated how, nearly forty years ago, when travelling on horseback in the southern province of Rio Grande, he saw a globe of lightning fall, traverse the fields for some instants, and then burst with a loud sound. Will none of the votaries of the camera at least attempt to fix a globular discharge whilst it is perambulating across the landscape?

In the absence of further information, we are disposed to take the charitable view that Count Mattei is ignorant enough of electrical science to imagine that he can permanently electrify his drugs, and we need not necessarily compare him with vendors of magnetic belts and other impudent impostors. But there can be no excuse for the unblushing incapacity in electrical matters of the Public Analyst of Paddington, F.C.S., F.I.C., who describes his tests of Count Mattei's blue, green, and white electricities as follows:—"To find if they possessed any special electrical properties they were placed singly in thin glass tubes; these tubes were suspended by silk filaments. Under such circumstances an electrical body would point one end to the north and the other end to the south. Not one of these came to rest in such a position; neither were any of them attracted by a magnet, as an electrical body would be. Hence, they certainly are not electrical."

In this connection we are sorry to notice that the *St. James's Gazette*, an otherwise respectably-conducted journal, has lately taken to inserting conspicuous paragraphs as original matter, which, when read, turn out to be advertisements of an electropathic quack. This is a clear case of imposture, and, if possible, is, journalistically, more disreputable than that of the advertiser.

**Harrogate.**—The Town Council have decided to apply for powers to light the town by electricity.

**Interurban Telephony.**—The trunk wire between Cologne and Coblenz is now completed.

**Chemnitz.**—The tramway at Chemnitz has been acquired by the Allgemeine Elektricitäts Gesellschaft, who intend to work the line by electricity.

**Paris.**—A fire broke out on Saturday evening at the Grand Café, Boulevard des Capucines, owing to a short circuit of the electric light mains.

**Brighton.**—The foundation-stone of the Brighton Municipal electric light station was laid on Tuesday afternoon by the Mayor.

Digitized by Google

**Bale.**—A company has been formed by the firms Escher and Wys, Geigy, and the Oerlikon Maschinenfabrik for the electric lighting of Bâle by means of power derived from the Rhine.

**Bromley Local Board.**—This Board has decided to take the necessary steps to obtain a Provisional Order, and to request Prof. Kennedy to advise the Clerk on details.

**The Elmore Companies.**—It is announced that M. Secrétan, late of the Société des Métaux, has accepted the position of manager of Elmore's French Patent Copper Depositing Company.

**North Shields.**—In accordance with a recent decision of the Tynemouth Town Council, a notice has been published intimating that the Corporation of Tynemouth intend to apply for a Provisional Order.

**Electric Lighting Statistics.**—According to a table prepared by Dr. Bersillon the number of arc lamps used in Paris in 1885 was only 68; last year the number had risen to 393 arcs and 6,188 incandescents. The fires officially stated to have been caused by electricity had risen in the same period from 1 to 33.

**Appointments Vacant.**—The Gravesend School of Science and Art is in want of a teacher in "Electricity and Magnetism," and of a teacher in "Mathematics and Theoretical Mechanics." Further particulars will be found in our advertisement columns.

**Finsbury Technical College.**—A course of six lectures on the chemical and physical properties of india-rubber and gutta-percha will be delivered at the above institution by Mr. Thomas Bolas, on Wednesday evenings, beginning next week. For further particulars, see our advertisement columns.

**Newcastle-on-Tyne.**—One afternoon last week the lid of an electric-light main junction box was blown into the air. Three or four people are stated to have been knocked down by the force of the explosion, but no one was hurt seriously. The cause of the explosion is believed to have been an accumulation of gas in the box from neighbouring tenements.

**Antwerp.**—The military telephonic system connecting the various points of the Antwerp fortifications, installed in 1881 and partly maintained by the Compagnie Belge du Téléphone Bell, has been since August 1, 1890, in the hands of the military authorities, who have entirely reconstructed the network, employing Dejongh transmitters and Goffart receivers.

**The Frankfort Exhibition.**—We learn from the *Elektrotechinsche Rundschau* that Messrs. Seimen and Halske, besides an extensive exhibit of continous current plant, are also building a 400 horse-power alternator for the Frankfort Exhibition. Transformers of all sizes are being made, including one for a tension of 40,000 volts, to be used for testing cables.

**The Electric Light and the Defence of the Thames.**—The operations that took place last week on the Thames below Gravesend with the object of testing the efficiency of the electric light for defence purposes were much interfered with by a dense fog that hung about the river. Further operations will take place at a future period.

**Kingston-on-Thames.**—At a special meeting of the Town Council last week it was decided to apply for a Provisional Order. Last year the Council made a similar application in conjunction with the Surbiton Improvement Commissioners and the Hampton Wick Local Board, but met with a refusal on the ground that the Board of Trade had no power to grant a Provisional Order to combined authorities.

**Edinburgh Exhibition.**—The Edinburgh Exhibition, which was opened by the Duke of Edinburgh on May 1st, was closed on Saturday evening last. The total number of visitors to the exhibition has been 2,414,129. The number of visitors to the Edinburgh Exhibition of 1886 was 2,769,779. On Saturday night the number of persons admitted to the exhibition was 25,204.

**Royal Institution.**—At the general monthly meeting of this Institution, Professor Viriamu Jones, M.A., Mr. C. N. Nicholson, M.A., Mr. John Hartley Perks, and Sir James Stirling were elected members of the Royal Institution. The special thanks of the members were returned to Dr. J. A. Fleming for the presentation, on behalf of Professor Elihu Thomson, of the apparatus employed by Professor Thomson in his experiments on electro-magnetic repulsion.

**London Chamber of Commerce.**—At the meeting of the Electrical Trades' Section Committee, announced for Monday next, at 4 p.m., the following subjects are on Agenda paper:—(1.) Board of Trade rules; (2.) Proposals in regards to Correspondent's duties; (3.) Mr. Crompton's scheme for the interchange of useful information; the approaching expiration of European Commercial Treaties; American Tariff; other matters.

**The Junior Engineering Society.**—On Friday afternoon last a very numerous party of members of this Society visited the Royal Arsenal, Woolwich, by special facilities afforded through the kindness of the Director General of Ordnance Factories. The Inaugural Meeting of the Society's tenth session takes place on the 21st inst., when Professor S. P. Thompson, President-elect, delivers an address on "Electro-Magnetic Mechanisms."

**"St. Martin's-le-Grand."**—We have pleasure in noticing the advent of *St. Martin's-le-Grand, the Magazine of the Post Office*. This magazine takes the place of the now defunct *Blackfriars*, and is the same size as that journal. We think the change of title a great improvement. The first number contains Mr. Preece's Paper on "Sanitary Aspects of Electric Lighting," and a quantity of other matter of an interesting character. The magazine is well got up, and we hope will prove a success.

**Subways for Supply Mains.**—At the last meeting of the Strand Board of Works Mr. Emden's proposal respecting a subway to be made for the storing of the pipes and wires of the gas, water, and electric light companies was discussed, and the matter referred to the Works and Parliamentary Committee with a view to united action being taken. A memorial will be promoted by all the districts in London to induce the County Council to bring a Bill into Parliament dealing with the subject.

**New York Subway Rentals.**—The Consolidated Subway Company has notified to the New York electric light companies that they must pay the rentals already due and overdue for duct space in the New York subways; and that in the event of their failure to pay these rentals or a portion of them, the Subway Company will either cut their wires and cables or remove them, or both. The Companies have in the meantime protected themselves by an injunction of the New York State Supreme Court.

**Personal.**—Mr. Magnus Volk having fulfilled his engagement with the General Electric Power and Traction Company, his connection with that Company has ceased, and he is now completing some new types of electrical measuring instruments.—Mr. A. J. Lawson, A.I.E.E., late Canadian agent of the Brush Electrical Company, Montreal, has recently been appointed superintending electrical engineer to the Siam Electric Light Company, and left for Bangkok on Monday last to instal and run a Mordey Alternate Current Plant of 10,000 lights.—Mr. A. W. Jones has resigned the post of chief electrician to the Exeter Central Station, and has joined the Laing, Wharton, and Down Construction Syndicate.

**The Coffin Electric Welding System.**—We learn that in a few weeks this system will be in actual work in this country. It is proposed to erect a small plant to demonstrate the efficiency of the process in London, the power being taken from an existing public lighting installation. It is claimed by the Syndicate who hold the British patents, that a single arc-light circuit will weld bars of metal, and an incandescent circuit is all that is required for the smaller weldings, thus saving the expense of laying down a separate installation on the transformer principle.

**Chemically Pure Zinc.**—According to *l'Electricien*, M Cahaigne, of Paris, has succeeded in producing chemically pure zinc on a commercial scale and at a price but little higher than that of ordinary zinc. MM. Pouchard, Mathioux et Cie., makers of electric clocks, have used Cahaigne zinc rods in the Leclanché cells employed by them. The cells in question furnished current for about 90 hours, and the consumption of the chemically pure zinc amounted to 28 grms. per cell, while the

Digitized by Google

consumption of ordinary well-amalgamated zincs amounted to 36 to 38 grms. The Cahaigne zinc was, moreover, uniformally consumed, while the amalgamated rods were very irregularly attacked.

**Telephonic Communication between London and Paris.**—The work in connection with the establishment of telephonic communication between London and Paris is being pushed forward very rapidly on this side of the Channel, and has made such satisfactory progress during the last few weeks that it is stated communication will be established early in the new year. Some alterations, however, have been decided upon in reference to the route to be taken by the cable. Instead of crossing the Channel and touching the English coast near Hythe, it has been decided to land it at St. Margaret's Bay, where it will be connected with the special wire running from this point *viâ* Dover, Folkestone, Ashford, and Maidstone to London.

**The Boston Street Railway Power Station.**—The work on the foundations of this, the largest electric power station in the world, was, says the *Electrical Engineer* of New York, begun about the 1st of October, 1889. The foundation work is now completed, about 8,000 piles having been driven, and about 35,000 tons of concrete and masonry used in its construction. The dimensions of the boiler-house are 158ft. by 79ft. 6in., and six 500 horse-power Babcock and Wilcox boilers will be put in. The chimney rests on a base 56ft. square, tapering to 30ft. at the top of the foundation; it is now 192ft. high, and will ultimately have a height of 252ft. Power will be furnished, to start with, by six 1,000 horse-power engines installed in an engine-room 176ft. long by 150ft. broad. By the 1st December the erection of the boilers and engines will be actively commenced; and it is expected that by May, 1891, some of the engines will be ready for work.

**West Metropolitan Tramway Company.**—Referring to the fine imposed on the West Metropolitan Tramway Company, at the instance of the Hammersmith vestry, for the bad state of repair of the roadway in Uxbridge-road, the secretary of the company states that the decision will be appealed against, and that evidence will be produced showing that the alleged defects were chiefly in the part of the roadway which the vestry has to maintain. He adds: For the past two years the tramway company has been urgently pressing the Hammersmith vestry for its sanction to adopt electricity on their lines, which would necessarily involve an entire relaying of the roadway with new material. Parliament has already sanctioned the proposal, and the local boards, with the exception of those of Hammersmith and Acton, have also given their consents. It would be pure waste of money to do extensive repairs now which would all have to be done a second time.

**St. Pancras.**—The first stone of the St. Pancras municipal electric light station was laid on Wednesday afternoon. Prof. Henry Robinson (the electrical engineer to the Vestry) stated that the installation, which was now being carried out by the Vestry under his direction, would serve the south-western part of the parish, and was intended to be followed by further stations to serve the rest of the district if the result proved as satisfactory from a commercial standpoint as was anticipated. The "three-wire system" had been adopted, and the plant would be capable of supplying current to 10,000 16 candle-power incandescent lamps simultaneously. High-tension current would be provided on a separate set of mains to the 90 public lights in the streets. There would further be six sets of accumulators capable of supplying 800 to 900 lights during the period of minimum demand. Provision had been made at the outset for five miles of distributing mains, designed to carry current for 25,000 lamps burning simultaneously.

**Heavy Telegraph Work.**—The interest in the political demonstrations recently made in Newcastle was evinced in the heavy call by the Press upon the telegraph, the demand made upon it exceeding anything that had before been experienced there. There were 17 Wheatstone circuits arranged. To reach the long distances across to Ireland from Newcastle 10 repeaters had to be inserted at different parts of the lines. These were put in on the English side at Nevin, in South Wales, Haverford West, and Llanfair, and there was another at Edinburgh to reach Belfast. The longest wire run was worked from Nevin to Cork, 600 miles. Seventeen offices were supplied direct with a verbatim report and 52 with a column summary. The number of words despatched over these circuits on Friday, October 17th, was 121,000. On Saturday, the 18th, 79,000 words were telegraphed. On Monday, the 20th, the number of words signalled was 99,000; the total number of words transmitted during the three days' demonstration being 299,000.

**Vibrations of an Incandescent Platinum Wire when traversed by an Intermittent Current.**—In a recent number of the *Comptes Rendus* M. Argyropoulos describes the following experiment:—Take a platinum wire about ·7m. long and a fraction of a millimetre in diameter, and pass a current through it until it becomes incandescent; then, if the wire is stretched in a horizontal position and Foucault interrupter is inserted in its circuit, the wire immediately vibrates and becomes subdivided into a series of waves having well-marked ventral segments and nodes. The number of segments is augmented by very slowly decreasing the tension of the wire. On increasing the tension the number is diminished until the incandescent wire vibrates transversely with a single ventral segment at the middle. M. Argyropoulos employed a battery of from 45 to 50 Bunsen cells, and screwed down the commutator until the wire became white hot; then, if the commutator was released, the stretched wire immediately commenced to vibrate.

**Aluminium in the Electric Arts.**—In an article under this title the *Electrical Engineer* of New York remarks that the considerable reduction in the price of aluminium may result in its extended use in the electric arts. Its great lightness and strength make it eminently adapted for overhead line work, its specific gravity being but 2·6 as compared with copper, which has a specific gravity of 8·9. Its resistance, it is true, is nearly twice that of copper; but on account of its low specific gravity, its weight would only be about four-sevenths that now required in copper for the same conductivity. Looking still further, there are many of the parts which go to make up an electric car that could be made of aluminium, and which would tend materially to reduce the car weight without affecting its strength or efficiency. Thus, among other details, the trolley wheel and trolley pole might be made of aluminium to considerable advantage. If to this were added the substitution of aluminium for iron and brass now employed on the truck and motors, outside of the magnetic circuit, the reduction in weight would be an important factor tending to economy.

**Obituary.**—We regret to record the death at Corinth, on 19th ult., of Chevalier Edward Rosenbusch, at the age of 53. The deceased was born at Einbeck, in Hanover, and first landed in Malta as an *employé* of the Mediterranean Extension Telegraph Company. On the resignation by Mr. Andrews of the post of Superintendent, the Directors appointed Mr. Rosenbusch his successor in 1869. He introduced the electric light and the telephone into Malta, to a considerable extent at his own expense. When the Eastern Telegraph Company acquired the plant of the Mediterranean Extension Company, Mr. Rosenbusch was tranferred, first to Patras and afterwards to Corinth, where he continued to reside until his death. Mr. Rosenbusch was appointed Member of the Institution Civil Engineers in 1871, was decorated with the Order of the Crown of Prussia in 1876 for services rendered to the Royal Astronomical Society of Berlin. The Italian Government conferred upon him the Orders of the Corona d'Italia and of SS. Maurizio e Lazzaro for services rendered to the Italian refugees in Malta; and the Sublime Porte, that of the 3rd Class of the Medjidie. He leaves a widow and six children.

**Silver Refining by Electricity.**—The following method of refining silver electrically is described in the *Engineering and Mining Journal*:—The method is most suitable for the refining of auriferous silver containing about 11 per cent. of gold, the cost in this case being only about 14 cents per pound. The principle upon which the process is based consists in using in an ordinary electrolytic bath anodes of an argentiferous matte, and a thin plate of pure silver as the cathode. The bath consists of a very weak solution of nitric acid containing about one per cent. of the acid. The anodes, which are about

Digitized by Google

one-half inch thick, with a surface of about 13·5 square inches, are placed in muslin bags, which retain the gold, platinum, peroxide of lead, and similar foreign materials contained in the matte. The current used is 150 amperes, and the potential difference between the plates one volt. During the whole period of work brushes are kept moving up and down the silver plates, sweeping off the silver deposited into troughs put for the purpose at the bottom of the bath. These troughs are removed from time to time, and the silver taken out and sent to the furnace. If the matte contains copper, this is dissolved by the nitric acid, but is not deposited on the cathode.

**International Telegraph Statistics.**—The following figures for the year 1888 may be of interest:—

| Country. | Population per office open. | Square miles per office open. | Telegrams per head. | Miles of wire per office open. |
|---|---|---|---|---|
| United Kingdom | 5,300 | 17 | 1·4 | 26 |
| France | 4,125 | 22 | 1·36 | 16 |
| Germany | 3,000 | 13 | ·35 | 13 |
| Austro-Hungary | 7,520 | 46 | ·15 | 14 |
| Russia | 27,280 | 2,250 | ·08 | 37 |
| Italy | 8,200 | 30 | ·2 | 16 |
| India | 72,555 | 241 | ·01 | 36 |

It is curious to note that while such diverse countries as England, France, and India obtain about the same number of messages per employé, viz., respectively, 482, 500, and 475; in Italy they require only 6,897 employés to deal with 7,061,131 telegrams, or over 1,000 messages per employé.

**Globular Lightning.**—In a recent communication to the Académie des Sciences, M. H. Faye gives a long list of globular lightning phenomena witnessed during a storm at Saint Claude in August last. The list was collected by M. Cadenat Professor of Physics, at the Saint Claude College, and the following is a sample story. M. Mermet stated that he saw three fireballs fall into a courtyard at the back of his house. Two of them moved slowly along at some little height above the ground. The third struck against an iron bar resting on a wall, rebounded, and then travelled along at a distance of some few metres above the soil: suddenly changing direction, it entered a passage and descended a staircase at the end. It then passed between the wall and an open door, destroying the lock and ironwork, into the street, where it burst, making a big hole in the door and splitting it from top to bottom. M. Mascart remarked at the end of this communication, that it would be prudent to "make some reserves" as to the actual existence of globular lightning, at least in certain cases where it appeared to have altogether extraordinary properties. On the other hand, the ex-Emperor of Brazil testified to having seen a case of globular lightning in the Province of Rio Grande forty years ago.

**Electric Lighting (Transmission of Power) in Switzerland.**—The following figures with regard to the position of the electric light in Switzerland may be gathered from a recently published table. The total number of installations at the end of 1889 was 351, of which 11 only were central stations. Of the 340 isolated plants no less than 182, or 51 per cent., were in mills or factories of various descriptions. The number of dynamos running at the end of last year was 408, having a total output of 5,150 kilowatts, or an average of 12·6 kilowatts each; these machines supplied 51,155 incandescent and 845 arc lamps. The eleven central stations are those at Aussersihl, Brunnen, Faido, Geneva, Interlaken, Lausanne, Leukbad, Lucerne, Martigny, Meyringen, and Vevey-Montreux. The stations at Brunnen, Lucerne, and Vevey-Montreux are on the alternate-current transformer system, the others employing the continuous-current system. Power is derived in 177 cases from turbines, in 138 cases from steam engines, in 32 cases from gas engines, in 4 cases from electric motors. Besides these installations there are 24 transmission of power installations, 7 electro-motor stations, and 41 accumulator installations. The power transmitted varies from 2 to 280 horse-power, and the distance from ·05 to 10 kilometres. The number of machines is 76 and their capacity 1,714 kilowatts. The electric tramway at Vevey-Montreux, 10·6 kilometres long with 7 motor cars, and the electric rope railway on the Bürgenstock are included.

**Indurated Fibre Conduits.**—According to the *Electrical Engineer* of New York, some indurated fibre pipes used for underground telephone work in Philadelphia have stood severe tests during a period of over eighteen months. This material is made from long wood fibres, separated, washed free from all saps and gums, moulded while in a pulpy state into the requisite size and shape, and then subjected to great hydraulic pressure. After this it is treated and hardened by a special chemical process and rendered impervious to moisture, acids, or gas. It is extremely tough and durable, and will withstand great crushing strains. The tensile strength is about 1,100lb. to the square inch. Its weight is about one-fifth that of iron for equivalent service in pipe form, and it will resist over 200 degrees of heat. For electric light subway work the manholes have a bottom of asphalt concrete, upon which is placed a flooring of indurated fibre an inch or more in thickness. The walls of the chamber are similarly treated. The wires are carried through these manholes in rubber tubing to the pipes, which are generally 1½in. inside diameter with ½in. shell, and are joined together with collars, in which they are fastened by means of screw threads. This system is, as already mentioned, in successful use in Philadelphia, where 40 miles are laid. In Detroit, the Detroit Electric Light Company have about 20,000ft., and the local Edison Company have some also. Specimens that have been underground for four years have been recently exhumed and tested, and showed no change whatever.

**The Electric Storage Battery Company's Accumulator.**—The storage battery now being manufactured by the Electric Storage Battery Company of Philadelphia bears a striking resemblance to the Laurent-Cely accumulator described in *The Electrician* of May 30, 1890. The conclusion arrived at by this Company is that the lead reduced from the chloride possesses the best properties for battery purposes. To obtain the chloride, commercial lead is melted and converted into a finely divided powder. The finely divided lead is then dissolved in nitric acid and precipitated as chloride of lead by the addition of hydrochloric acid. The white chloride of lead so obtained, after being thoroughly washed and dried, is mixed with a certain proportion of chloride of zinc, and the mixture brought to a molten state in a furnace. The fused mixture is then poured into square moulds and allowed to cool. The square blocks of chloride so formed, and which are destined as the active matter in the plates, are then placed in a mould prepared for their reception and a grid of lead cast around them under pressure. The grids are then packed between zinc plates and placed in a tank containing dilute chloride of zinc. There is thus formed a voltaic couple, the action of which is to dissolve the zinc chloride and to extract the chlorine from the lead chloride contained in the blocks. The last trace of chlorine is removed from the plates by washing and then placing them in a tank containing nitric acid, and passing a current. This action also opens the pores and leaves a pure lead sponge in the grid. The plates intended for positives are then packed tightly between perforated ebonite boards, and formed into peroxide in dilute sulphuric acid. The standard cell consists of 9 positive and 10 negative plates, having a capacity of 230 ampere hours, and weighing complete 34lb. This gives a capacity of 9·9 ampere hours per lb. of plate and 18 ampere hours per lb. of total active material. In size the plate is 5¾ × 6in. In the traction cell the weight of active material and of the grids is, respectively, 12¼ and 10⅝lb. Four cars on the Lehigh Avenue Street Railroad, Philadelphia, have, says the *Electrical Engineer*, of New York, been operated continuously during the last four months with cells of this type. This road has numerous curves, and gradients as heavy as 5¼ per cent. These have taxed the cells to their utmost, the 100 cells on each car frequently being discharged at the rate of 45 electrical horse-power. During the month of August, these cars alone carried 59,000 passengers, with frequent loads of 100 passengers on a car. The batteries have frequently made runs of 63 miles with a single charge under these conditions. A storage battery station on this system has also been for some time in operation at Germantown, Pa. The plant consists of 512 cells, in eight series of 64 each, and has a capacity of 1,600 ampere hours.

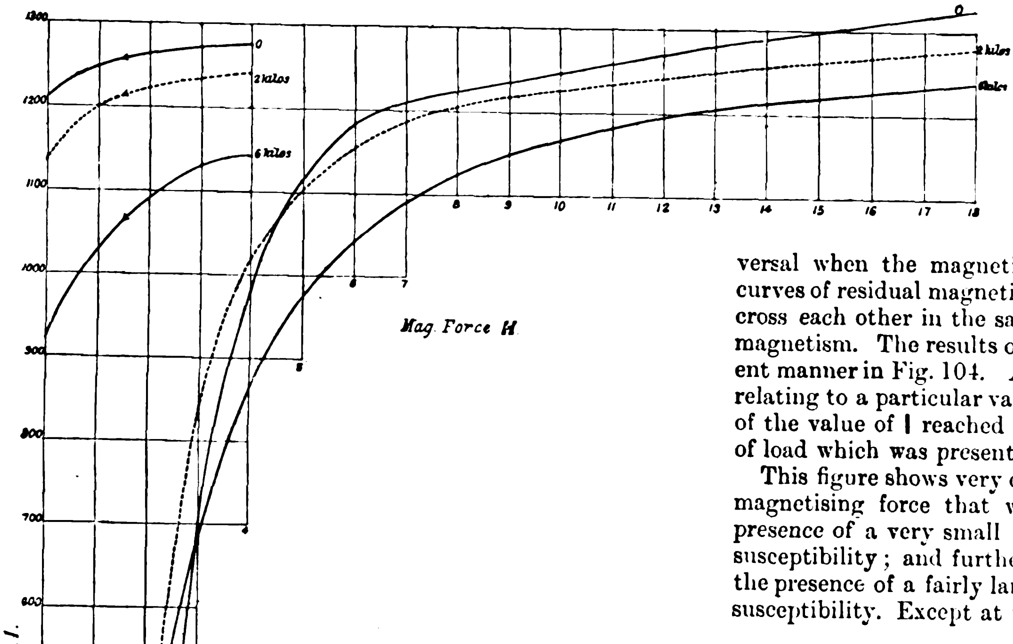
## MAGNETISM IN IRON AND OTHER METALS.*—XXXIV.

BY PROF. J. A. EWING, F.R.S.

(*Continued from page 733.*)

§ 124. **Effects of Longitudinal Pull in Iron.**—Turning now to iron, we find that much more complex variations of magnetic quality are produced by longitudinal stress. We have to distinguish between two cases, that of soft annealed iron, and that of iron which has been hardened by a mechanical operation such as stretching, which has given it a permanent set. With hard metal the effects of stress are in general much greater than with annealed metal. Both cases have this in common, that the presence of any moderate amount of longitudinal pull increases the susceptibility when the magnetisation is weak, but reduces the susceptibility when the magnetisation is strong. We have here the phenomenon of the Villari reversal to which allusion has already been made. But in the case of hard metal, where it is possible to apply a stronger pull without permanently altering the characteristics or structure of the piece, it appears that the presence of a sufficiently great amount of stress may be unfavourable to magnetisation, even in the earliest stages of the magnetising process. These, as well as other effects of stress will be best appreciated by means of a careful study of curves which exhibit the process of magnetisation in iron wires pulled by various amounts of hanging load. The wires, in the experiments to be described, were of such a size that each kilogramme of load corresponded to a stress of about 2·2 kilometres per square mm.



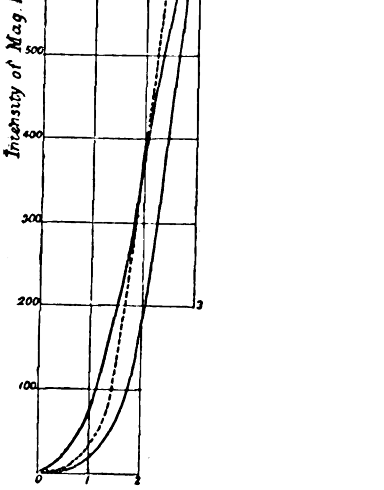


Fig. 103.—Magnetisation of Annealed Iron under Various Amounts of Longitudinal Pull.

§ 125. **Annealed Iron under Pulling Stress.**—Fig. 103 shows, by curves of I and H, the magnetisation of a wire of soft annealed iron under various amounts of longitudinal pull (no load, 2 kilos, and 6 kilos).* The curve for no load lies at first lowest, and finally highest. Each curve, in fact, lies at first lower, and afterwards higher, than a curve for any greater amount of load. Thus, the presence of load is favourable to magnetisation when I is small, but unfavourable when I is great. And the curves obtained by removing the magnetising force (which are shown to the left in the figure) preserve throughout their whole course the relative places with which they start, the differences between them becoming only accentuated as the magnetising force is reduced to zero. Thus, the presence of pulling load is unfavourable to the residual magnetism left after a strong field has been applied; though, as another experiment has shown, it is favourable to the residual magnetism that is left after magnetisation by a weak field Its influence on the residual magnetism is, in fact, of the same kind as its influence on the induced magnetism; both suffer reversal when the magnetisation is sufficiently increased. The curves of residual magnetism (which are not drawn in the figure) cross each other in the same manner as the curves of induced magnetism. The results of this experiment are shown in a different manner in Fig. 104. A series of curves are drawn there, each relating to a particular value of the force H, to show the relation of the value of I reached by applying that force to the amount of load which was present when the force was applied.

This figure shows very clearly that except under the strongest magnetising force that was applied in the experiment, the presence of a very small amount of pulling load increases the susceptibility; and further, that except in the weakest fields, the presence of a fairly large amount of pulling load reduces the susceptibility. Except at very low and again at high magnetisation, there is maximum of a susceptibility occurring with a particular load; and the value of this load becomes smaller as the magnetisation is increased. This maximum disappears in the lowest fields, no doubt only because the load is insufficiently great to show it.

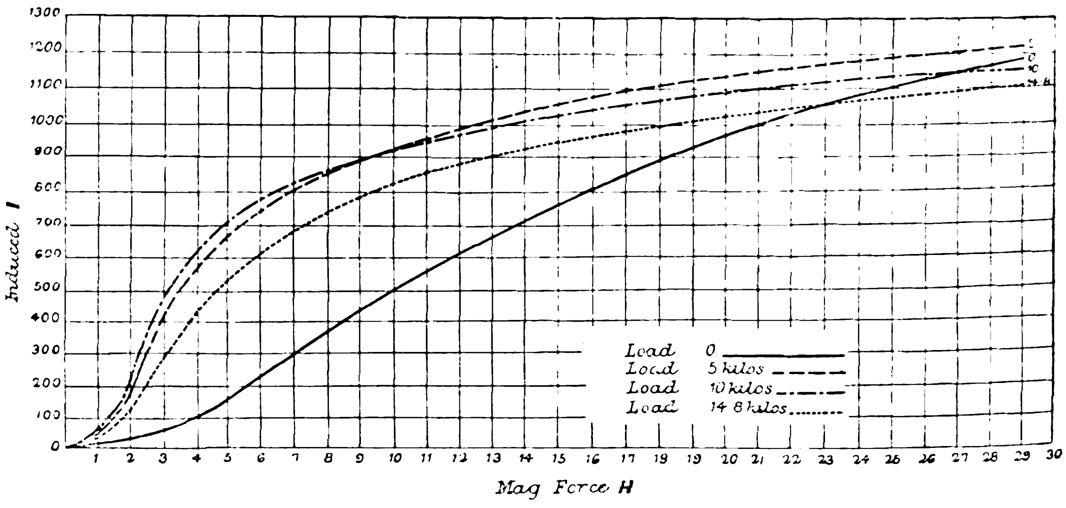

Fig. 105.—Magnetisation of Hardened Iron under Various Amounts of Longitudinal Pull.

§ 126. **Hardened Iron under Pulling Stress.**—Figs. 105 and 106 show the effects of various amounts of longitudinal pull on iron wire which had been hardened by stretching beyond the an elastic limit. Fig. 105 gives the induced magnetism, and Fig. 106 gives the residual magnetism, both in relation to H, the process of magnetising being performed, as in previous examples, while a constant load hung from the wire.

The first thing to observe here is the immense effect which a moderate amount of pull has in augmenting the susceptibility with respect to feeble magnetising forces. On the other hand, when a condition approaching saturation is reached, the presence

* All rights are reserved.

* *Phil. Trans.*, 1885, plate 64.

Digitized by Google

of load is unfavourable to magnetisation; in other words, we have, as before, the Villari reversal. But it is now to be noticed that even in the weakest fields the susceptibility is increased only when the amount of the load is moderate: to apply stress

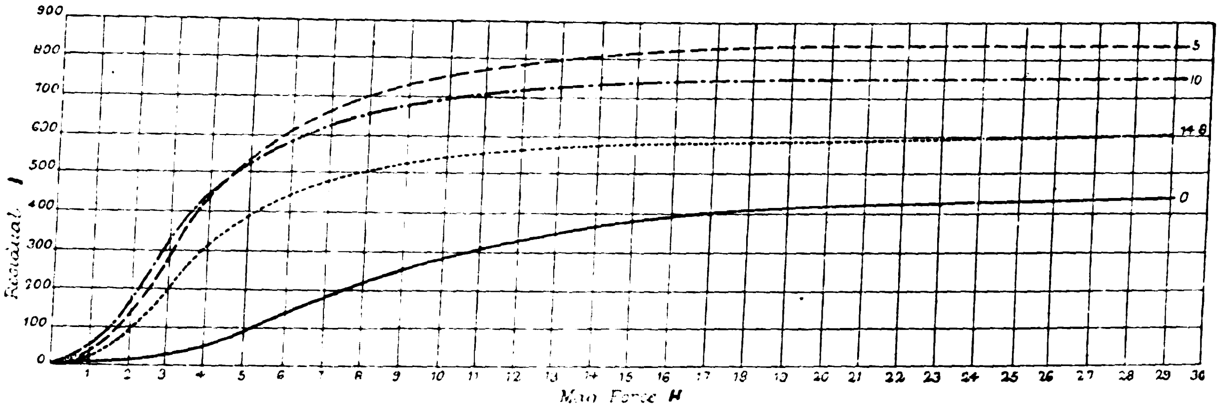

Fig. 106.—Residual Magnetisation of Hardened Iron under Various Amounts of Longitudinal Pull.

beyond a certain amount is prejudicial, whether the magnetisation be strong or weak. This is shown by the fact that the curve for 14·8 kilos. lies below the curves for 5 and 10 kilos. thoughout its whole course.

The same remarks apply to the residual magnetism (shown in Fig. 106). The influence of stress on it is even greater.

Fig. 107 shows, in the same way as Fig. 104, the results of another experiment of the same kind, in which a piece of the same iron wire, also hardened by stretching, was magnetised under

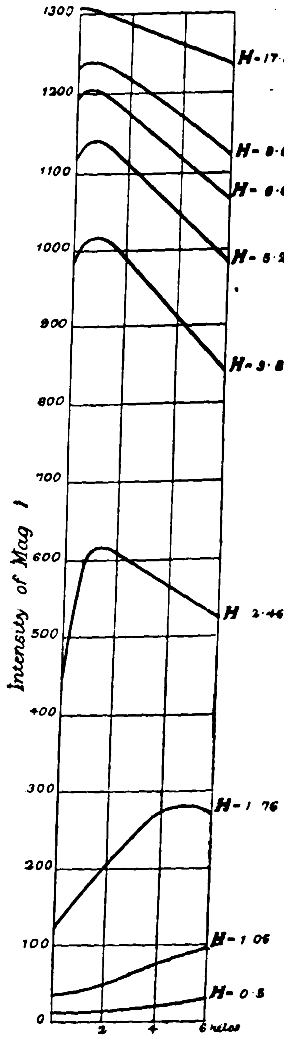

Fig. 104.—Magnetisation of Annealed Iron under Various Amounts of Longitudinal Pull.

a series of loads which in this case ranged up to about 19 kilos. This figure shows very clearly that a moderate amount of load is more favourable to magnetisation than either less load or more; the exact amount which is most favourable depends on the degree of magnetisation, being less in strong fields than in weak ones. It varies, in this example, from about 10 to 5 kilos, for the range of magnetic forces with which the experiment deals.

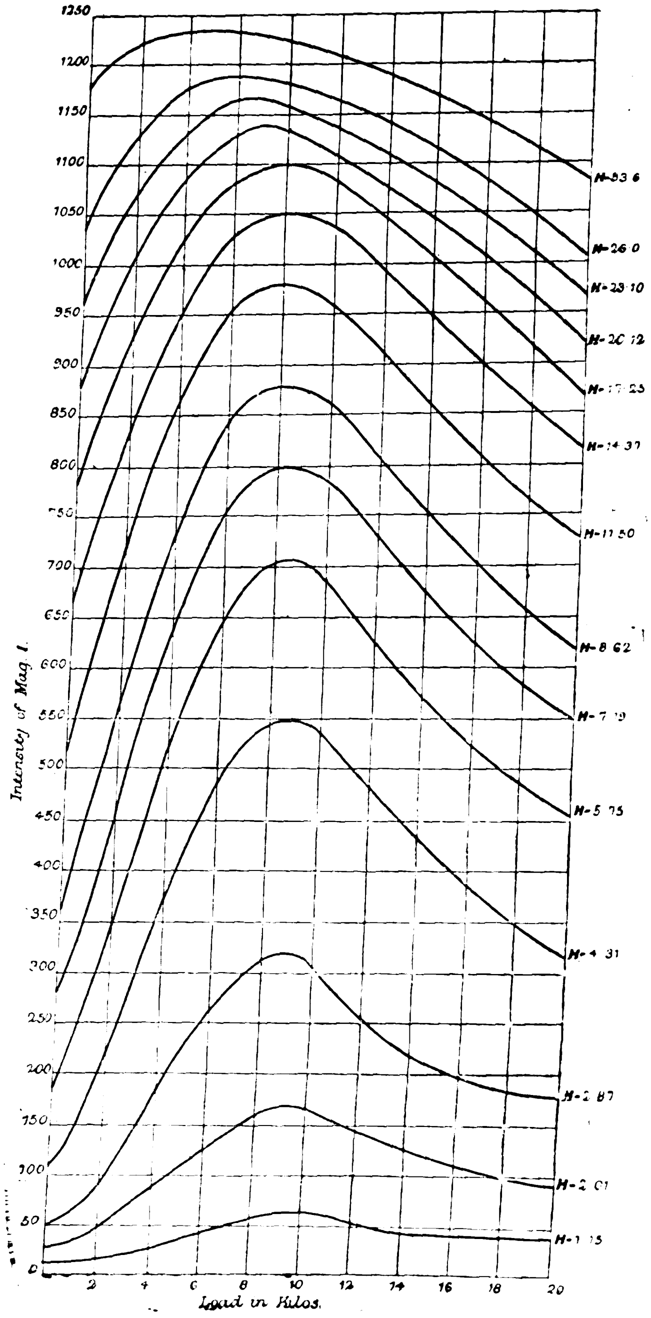

Fig. 107.—Magnetisation of Hardened Iron under Various Amounts of Longitudinal Pull.

The effects of pulling stress on the susceptibility of steel are generally similar to the effects in iron.

## DRUM ARMATURE WINDING.

BY F. M. WEYMOUTH.

*Introductory.*

It frequently happens that men who have served their apprenticeship in mechanical engineering, and, perhaps, had considerable experience in that line, ultimately drift into electrical work. If of an inquiring turn of mind, such as, indeed, may be taken to be generally the case, they will find a variety of problems arise before them in connection with their new sphere of occupation, for which to them there is no immediate solution. Many books abound; but some of these are expensive, or else cover so much ground that much detail is necessarily omitted. The drum armature in itself involves a host of problems; taking its theory alone it is very puzzling to the new comer, and mechanical considerations also of all sorts demand attention. It is the object of these articles to put some of these mechanical considerations before younger readers. As to the theory that was treated much at large in another Article (on the Generation of Current and Potential in Drum Winding, see *The Electrician* of July 16th, 1889).

Various methods have been adopted from time to time by different inventors and makers to put this type of winding into a practical form. Among the many points for consideration that occur, perhaps the most prominent is that involving the question as to how to take the cross-connections at the end of the armature round the spindle. It is thus of interest to observe for one thing in what different ways this particular

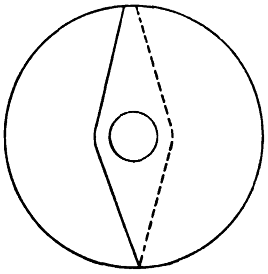

Fig. 1.

difficulty has been surmounted, and the "end-winding," as it is termed, arranged. It may be true that in the case of armatures for small currents, and wound with flexible wire, this difficulty may not be very great. But in dealing with heavy currents and conductors of large section, it is different, and many points of mechanical construction arise for consideration; and it is with these we shall be mostly concerned in the course of our remarks. We may state here, parenthetically, that though some of the sketches that will accompany this article will be taken from designs actually carried out, all will not, but will merely illustrate principles of design without pretending to be actual representations of any particular machines. Further, it may be added that we shall confine ourselves almost exclusively to armatures for two-pole machines.

Dealing for the present with wire-winding for light currents, we meet with the most simple and crude of all armature winding in Siemens' wire wrapping. This winding consists fundamentally as shown in Fig. 1, and supposing a single turn per section, in merely carrying the wire from one commutator segment, say, along the periphery of the drum parallel with the axis, across the further end, giving it a slight bend to one side to get past the spindle, and so back again on the other side, repassing the spindle, and then joining it to the next commutator lug from whence it started, or in irregular winding to some other lug. In practice, however, the wire may be carried round many times before being joined up to the lug of the next commutator segment. Each "section" of the winding is thus said to be composed of so many "turns;" and while there may thus be any number (within reason) of "turns per section," there are as many "sections" as there are segments in the commutator, neither more nor less. All the turns in a section may lie in approximately the same plane, carefully insulated from each other, and each section likewise from neighbouring sections, and from the core. There may hence be in a winding of this sort a large total number of turns of the single wire; and as the volts depend for one factor on the aggregate of the areas enclosed severally within half the number of these single coils or turns, it will be seen that this form of winding is particularly suitable for small currents and a high pressure, for few amperes but many volts.

It will now become obvious that in a fully wound armature of this sort, especially when the wires lie in two or more layers on the periphery of the drum, there will be a great accumulation of wire at each end, giving the ends of the armature a more or less hemispherical shape, where the coils overlie each other, as shown in Fig. 2. The current courses round the armature in one section as many times as there are turns in it, thence to a commutator segment, whence again, supposing the segment not to be in contact with a brush, to another section. Now, as each turn round the armature means virtually the opportunity of acquiring potential, a considerable difference of pressure accumulates between each section as a whole, and so between each commutator segment, rendering special care necessary as to their insulation.

But now, instead of each section of the winding being composed of one long length of wire carried round many times, the several turns being "in series" with one another, let us suppose that each "turn" consists of a separate wire, and the "section" a group of wires all carried round together, with all their ends at one end of the section connected to one commutator lug, and all the other ends to another lug. The several "turns" would now be connected "in parallel." The current, instead of being able only to flow through the turns one after

Fig. 2.

the other, would now flow through them all at once as they lie side by side, and thus would go only *once* round the core lengthways between any two segments of the commutator. The effect will hence be noted. The aggregate of the areas enclosed within the several coils, as we may now term the sections, being considerably reduced, other things being equal, the volts will be proportionately reduced; and as the current is able to flow through all the wires in a coil at once, it meets with less resistance—the resistance depending for one thing on the sectional area of the conductor—and there will be a large current; in a similar manner there would be a greater flow of water under a given head through a large pipe than a small one. We thus find, in fact, that the conditions as compared with the former case are reversed, and we have many amperes, but few volts. It will be necessary to provide a larger commutator; for while the number of segments remains unaltered, these must be of a section sufficiently large to carry the now heavy current, and of a length sufficient to afford room for a suitable number of brushes to take it off.

But to return once more to the former case of many turns per section, we may consider briefly some of the merits and demerits of this particular form of winding apart from its adaptability for heavy currents. As is well known, and fully explained in our last article, the current in its course through the armature winding, pursues two paths from brush to brush; in fact, as it might, supposing it were possible to remove the core, and pull the wire all out into one large circular loop with the brushes on the opposite ends of a diameter, when the current would be able to flow along both sides of the loop from one brush to the other. Now, with too great a density of current, the conductors are liable to heat. Let us briefly consider this point. Take the case of two pipes conveying

Digitized by Google

water, one, say, 4in. diameter bore and the other 2in., and let us imagine the same delivery through each. Now, as the sectional areas of the two bores—or, in other words, of the fluid cylinders in each—will vary with the square of their diameters, it follows that the velocity of the water in the small pipe will be $2^2=4$ times the velocity in the large pipe. Now, confining ourselves to slow velocities (as with high velocities the analogy will not hold good for hydraulic reasons), and imagining a long length of piping, we now find that besides there being in the first place the necessity of four times the head or pressure to produce the higher velocity in the small pipe, there will be a still further increase of head necessary in the case of the small pipe, on account of the increased friction between the water and the internal skin of the pipe due to the higher pressure. Thus the point to be noted is, that in this small pipe as compared with the large, we find there is a waste of energy incurred due to this friction. If this be carried to an extreme, and an attempt be made to still further increase the delivery, the small pipe may end by bursting. Now to return to our electric conductors, we find this analogy to hold good. If it is attempted to force more than a certain quantity of electricity per unit of time through a given size of conductor, there will be similar waste of energy; only in the case of the electric current, this will show itself by the rise of temperature of the conductor; and this waste energy, in the form of heat, will be dissipated by radiation or convection. As the heating of the conductor will decrease its conductivity, there will likewise need to be a corresponding increase of pressure or potential. Similarly, also, if matters be carried to an extreme, and it be attempted to make the wire carry an undue amount of current, the wire will simply melt, or even burst, with a sudden increase of current, owing to the inside of the wire melting before the outside, and thus expanding quicker.

## THE CENTRAL STATIONS OF THE METROPOLITAN ELECTRIC SUPPLY COMPANY.

BY DR. J. A. FLEMING, M.A.

*(Continued from page 739.)*

The underground conductor system of this Company consists of iron conduits into which are drawn highly insulated mains, mostly Silvertown electric light cable (Class L), the size chiefly in use being $\frac{19}{16}$. The pipes are of iron, cast vertical and in nine foot lengths. These iron conduits are laid under the footways and split T pipes are inserted for the customers' "take off," but no junction or jointing boxes are used. The general system of main laying as devised by the engineer of the Company, Mr. Frank Bailey, is to lay the mains in "rings," drawing in the cable in short lengths, and taking both ends of each such length into the consumers' premises.

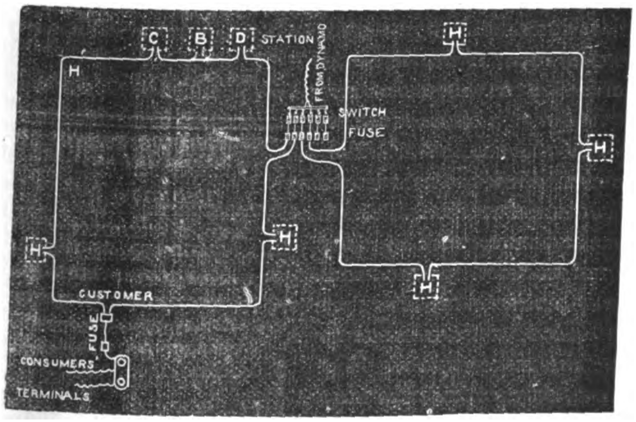

FIG. 10.—The Metropolitan Company's System of Ring Mains.

The diagram in Fig. 10 will make clear the arrangement followed. This arrangement in "rings" ensures that each customer gets his supply in duplicate, and the "ring" can be cut anywhere without interfering with the continuity of the supply of any consumer; and any section can be cut out and tested or replaced at any time. As the present price of coal necessitates working at a current density of about 600 amperes per square inch, it is clear that even if the "ring" is cut anywhere the cable will not become overloaded. Each of the sections or lengths from customer to customer is without joint*, and no making of T joints (always a difficult matter) is required. If a house at B Fig. 10 requires a supply the main from C to D can be disconnected from the cut-outs even with the current on, and one or both the halves of that section of the cable drawn out of the conduit and replaced by new lengths, the old lengths being returned to stores and used for other similar work; or one of the lengths may be drawn through with a new short length of the proper dimension attached to the end.

*(To be continued.)*

## THE CITY AND SOUTH LONDON RAILWAY.

The City and South London Railway was opened by the Prince of Wales on Tuesday last, and in a few weeks' time it may be expected that a regular passenger traffic will commence. The "royal train" having brought a number of guests from the City terminus, an inspection was made of the engine-room and other parts of the depôt at Clapham-road. Luncheon was afterwards served to a party of 250 visitors, among whom were many well-known engineers.

The railway is of the subway type, passing from King William-street, in the City, under the Thames, to Stockwell. The line has been constructed on a method, designed by Mr. Greathead, in the form of two circular iron tunnels 10ft. in diameter, driven throughout the London clay, and about 60ft. below the surface. The method of working resembles the sinking of a caisson. A steel shield was forced forward while material was excavated. When a sufficient advance had been made, a ring of cast-iron plates was built up, and a lime grout was forced into the space left by the sides of the shield between the lining plates and the soil. A speed of 16ft. per day was attained, and since the tunnels were commenced several other important works have been constructed, or are in progress, on the same plan. Near the Stockwell terminus an old water-course, consisting of gravel, with a considerable quantity of water, was encountered. The air-lock principle, for which this system is excellently adapted, was employed, and after some delay in providing the necessary machinery which it was hoped might have been unnecessary, the tunnels were satisfactorily completed. It was originally intended to work the railway by cable, but tenders were invited for running it by electricity, and eventually plans were submitted to the Company by Messrs. Mather and Platt, and the Company accepted this firm's scheme, which is based upon the experience obtained by Dr. Edward Hopkinson in the construction of the Bessbrook-Newry Narrow-Gauge Electrical Railway. The contractors employed Messrs. John Fowler and Co., of Leeds, to supply the boilers and engines, and Messrs. Beyer, Peacock and Company to construct the framework of the electrical locomotives. All the electrical plant has been carried out under the special superintendence of Dr. Edward Hopkinson, of Messrs. Mather and Platt. Dr. John Hopkinson, F.R.S., has acted throughout as consulting engineer, and Mr. G. A. Grindle as resident engineer.

The whole of the generating plant is situated at Stockwell, the suburban terminus of the line. It consists of three large Edison-Hopkinson dynamos, each worked independently by a vertical compound Fowler engine. The engines work at a steam pressure of 140lb. per square inch, and have been built of exceptionally massive proportions. They run at 100 revolu-

* In a former part of this article (see *The Electrician*, Oct. 31, 1890, p. 739) it was stated erroneously that the joints were made and vulcanised in place. On this method of Mr. Bailey's there are no joints in the mains at all.

## DRUM ARMATURE WINDING.

BY F. M. WEYMOUTH.

*Introductory.*

It frequently happens that men who have served their apprenticeship in mechanical engineering, and, perhaps, had considerable experience in that line, ultimately drift into electrical work. If of an inquiring turn of mind, such as, indeed, may be taken to be generally the case, they will find a variety of problems arise before them in connection with their new sphere of occupation, for which to them there is no immediate solution. Many books abound; but some of these are expensive, or else cover so much ground that much detail is necessarily omitted. The drum armature in itself involves a host of problems; taking its theory alone it is very puzzling to the new comer, and mechanical considerations also of all sorts demand attention. It is the object of these articles to put some of these mechanical considerations before younger readers. As to the theory that was treated much at large in another Article (on the Generation of Current and Potential in Drum Winding, see *The Electrician* of July 16th, 1889).

Various methods have been adopted from time to time by different inventors and makers to put this type of winding into a practical form. Among the many points for consideration that occur, perhaps the most prominent is that involving the question as to how to take the cross-connections at the end of the armature round the spindle. It is thus of interest to observe for one thing in what different ways this particular difficulty has been surmounted, and the "end-winding," as it is termed, arranged. It may be true that in the case of armatures for small currents, and wound with flexible wire, this difficulty may not be very great. But in dealing with heavy currents and conductors of large section, it is different, and many points of mechanical construction arise for consideration; and it is with these we shall be mostly concerned in the course of our remarks. We may state here, parenthetically, that though some of the sketches that will accompany this article will be taken from designs actually carried out, all will not, but will merely illustrate principles of design without pretending to be actual representations of any particular machines. Further, it may be added that we shall confine ourselves almost exclusively to armatures for two-pole machines.

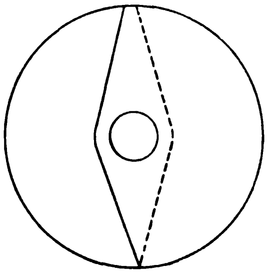

Fig. 1.

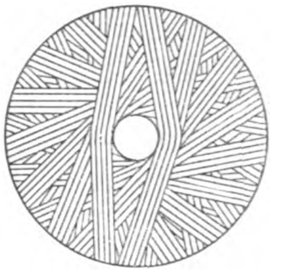

Fig. 2.

Dealing for the present with wire-winding for light currents, we meet with the most simple and crude of all armature winding in Siemens' wire wrapping. This winding consists fundamentally as shown in Fig. 1, and supposing a single turn per section, in merely carrying the wire from one commutator segment, say, along the periphery of the drum parallel with the axis, across the further end, giving it a slight bend to one side to get past the spindle, and so back again on the other side, repassing the spindle, and then joining it to the next commutator lug from whence it started, or in irregular winding to some other lug. In practice, however, the wire may be carried round many times before being joined up to the lug of the next commutator segment. Each "section" of the winding is thus said to be composed of so many "turns;" and while there may thus be any number (within reason) of "turns per section," there are as many "sections" as there are segments in the commutator, neither more nor less. All the turns in a section may lie in approximately the same plane, carefully insulated from each other, and each section likewise from neighbouring sections, and from the core. There may hence be in a winding of this sort a large total number of turns of the single wire; and as the volts depend for one factor on the aggregate of the areas enclosed severally within half the number of these single coils or turns, it will be seen that this form of winding is particularly suitable for small currents and a high pressure, for few amperes but many volts.

It will now become obvious that in a fully wound armature of this sort, especially when the wires lie in two or more layers on the periphery of the drum, there will be a great accumulation of wire at each end, giving the ends of the armature a more or less hemispherical shape, where the coils overlie each other, as shown in Fig. 2. The current courses round the armature in one section as many times as there are turns in it, thence to a commutator segment, whence again, supposing the segment not to be in contact with a brush, to another section. Now, as each turn round the armature means virtually the opportunity of acquiring potential, a considerable difference of pressure accumulates between each section as a whole, and so between each commutator segment, rendering special care necessary as to their insulation.

But now, instead of each section of the winding being composed of one long length of wire carried round many times, the several turns being "in series" with one another, let us suppose that each "turn" consists of a separate wire, and the "section" a group of wires all carried round together, with all their ends at one end of the section connected to one commutator lug, and all the other ends to another lug. The several "turns" would now be connected "in parallel." The current, instead of being able only to flow through the turns one after the other, would now flow through them all at once as they lie side by side, and thus would go only *once* round the core lengthways between any two segments of the commutator. The effect will hence be noted. The aggregate of the areas enclosed within the several coils, as we may now term the sections, being considerably reduced, other things being equal, the volts will be proportionately reduced; and as the current is able to flow through all the wires in a coil at once, it meets with less resistance—the resistance depending for one thing on the sectional area of the conductor—and there will be a large current; in a similar manner there would be a greater flow of water under a given head through a large pipe than a small one. We thus find, in fact, that the conditions as compared with the former case are reversed, and we have many amperes, but few volts. It will be necessary to provide a larger commutator; for while the number of segments remains unaltered, these must be of a section sufficiently large to carry the now heavy current, and of a length sufficient to afford room for a suitable number of brushes to take it off.

But to return once more to the former case of many turns per section, we may consider briefly some of the merits and demerits of this particular form of winding apart from its adaptability for heavy currents. As is well known, and fully explained in our last article, the current in its course through the armature winding, pursues two paths from brush to brush; in fact, as it might, supposing it were possible to remove the core, and pull the wire all out into one large circular loop with the brushes on the opposite ends of a diameter, when the current would be able to flow along both sides of the loop from one brush to the other. Now, with too great a density of current, the conductors are liable to heat. Let us briefly consider this point. Take the case of two pipes conveying

type on both the high-pressure and low-pressure cylinders, and are controlled by a powerful governor having a capacity of 750ft. lb., which is driven direct from the crank shaft by cotton stroke. The engines will indicate up to 375 horse-power each. The cylinders are steam jacketed, the high pressure is 17in. diameter and the low pressure 27in., stroke 27in. The pistons

Digitized by Google

are fitted with Mather and Platt's rings and springs, and the valves are specially arranged with multiple parts which reduces their movement considerably and still allows a very prompt action; as the ports are as close as possible to the end of each cylinder the loss of pressure by wire drawing is very small. Large and slow speed engines were selected on account of the very irregular nature of the work, it being considered that the high speed engines which are so largely and economically used for electric lighting could not so well cope with the sudden variations of load as the type which has been selected. The fly wheels are 14ft. diameter and 28in. broad, and drive the dynamos direct by means of leather chain belts 26in. wide.

It is a pity that the engine-room does not permit of a greater distance than 24ft. between the centres of the engines and that of the dynamos, since jockey pullies are rendered necessary. These are all very well as an expedient, but are not often to be met with in an important station of this kind. The engines are supplied with steam from six Lancashire boilers 7ft. diameter by 28ft. long, which are fitted with Vicar's mechanical stokers.

Livet's boiler setting is used, which provides flues of a varying area, and which, in conjunction with the mechanical stoker, is said to effect a saving of fuel, and certainly succeeded on the occasion of our visits to the depôt in preventing smoke. Two large feed water heaters are also supplied with brass tubes of ample surface for receiving the whole of the exhaust steam from the engine without back pressure.

The 202 kilowatt dynamos are fitted with all the latest improvements. The weight of the armature alone, which is drum wound with spiral ends, being about two tons, the weight of the entire machine being something over 17 tons. Each machine is capable of generating 450 volts and 450 amperes. There are three brushes on each rocking arm, each separately adjustable with a forward thrust and hold-off catch. The magnet limbs are exceedingly massive, each limb with its pole piece being over four tons, and the yoke of the machine weighs about three tons. The machines can be run either as shunt or compound as required. The total weight of copper wire on the magnet of each machine is nearly one and a-half tons. The present machines have an electrical efficiency of slightly over 96 per cent., and the commercial efficiency of the engine and dynamo, *i.e.*, ratio of the electric power available outside the dynamo to the indicated horse-power of the engine is over 75 per cent. Two dynamos are capable of working the trains on the line at any time.

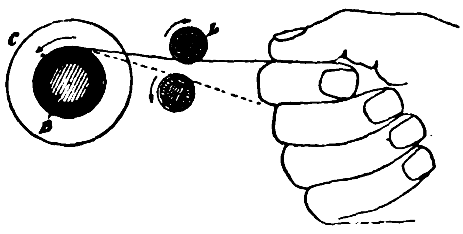
The current is conveyed from the dynamos to a general distributing and testing switch-board, fixed in a recess of the engine-house. From this board, which resembles in some respects the Westinghouse switch-board described in our last issue, the main circuits are taken to various parts of the line, and the current passing through each circuit is measured, suitable arrangements being provided for switching over from one circuit to another. The main cables have been manufactured by the Fowler-Waring Company, and consist of a copper core of $\frac{61}{14}$ B. W. G., insulated with Fowler-Waring insulating material and then lead-sheathed.

The working conductor is of channel steel carried on glass insulators, the joints being fished, and also connected with copper strips. The steel employed is of very high conductivity, and has been rolled specially for the purpose by the Shelton Iron and Steel Company, of Stoke-on-Trent. The working conductor is divided into sections for convenience of testing and carrying out repairs on the permanent way. The insulation obtained is thought by the contractors to be extraordinarily high. When the full pressure of 500 volts is on the complete system of working and feeding conductors, the leakage current does not exceed one ampere, so that the total loss by leakage is less than 1 horse-power; this is a small fraction of 1 per cent. of the total power required for working the line to its full capacity. The current is collected from the working conductor by sliding shoes of iron or steel arranged in a very similar way to that employed on the Bessbrook line.

Fourteen electric locomotives have been supplied by Messrs. Mather and Platt for working the line, each capable of developing 100 effective horse-power, and of running at from 25 or 26 miles per hour. The locomotives are constructed so that the shafts of the armatures are the axles of the locomotives. The driving wheels run at about 240 revolutions per minute when the locomotive is travelling at 20 miles per hour. The locomotives have a fixed wheel base and a motor is fitted to each axle, the axles not being coupled, but working independently. The current is conveyed from the collecting shoes through an ammeter to a regulating switch, then to a reversing switch, thence to the magnets and back through the frame-work of the locomotive to the rails. The locomotives are fitted with Westinghouse Automatic Air Brakes, and also a screw hand-brake, and they and the carriages are lighted from the working conductor by lamps in series. The compressed air for the brakes is stored in two cylinders, twelve inches in diameter, and the capacity is sufficient for three times as many stoppages as are likely to occur in any double journey. The trains, when loaded, will weigh 30 tons, and it is intended that ten trains shall be worked on the line at one time.

## WOOD'S MAGNET WINDER.

A clever little device is described in the *Electrical Engineer* of New York, by which a wire may be easily guided to and fro in winding magnet coils. Two guide spindles, L, are geared together and to the sleeve B on which the bobbin C is carried. The spindles have screw threads cut on them, and as they revolve in opposite directions, a wire guided by any thread is carried laterally in one



direction or in the other. The operator has only to move his hand up or down to engage the wire in one screw-thread or in the other. The speed of the guide spindles must be proportioned to the gauge of the wire. The difficulty in winding a magnet chiefly is met with at the ends rather than in guiding the wire, as every young electrician knows, but this method may sometimes prove to be useful.

## MEETINGS OF SCIENTIFIC SOCIETIES, &c.

**FRIDAY, November 7th.**

INSTITUTION OF ELECTRICAL ENGINEERS.

*7.30 p.m.* Students' Meeting.

ELECTRO HARMONIC SOCIETY.

*8 p.m.* Smoking Concert at St. James's Hall.

**MONDAY, November 10th.**

LONDON CHAMBER OF COMMERCE.

*4 p.m.* Meeting of Electrical and Allied Trades Section Committee.

**TUESDAY, November 11th.**

INSTITUTION OF CIVIL ENGINEERS.

*8 p.m.* Ordinary Meeting. Paper to be read: "Steam on Common Roads," by JOHN MCLAREN, A.M.I.C.E. Presentation of Medals, Premiums, and Prizes awarded at the end of last Session.

ROYAL VICTORIA HALL.

*8.30 p.m.* Lecture: "Columbus," by A. H. GILKES.

**THURSDAY, November 13th.**

INSTITUTION OF ELECTRICAL ENGINEERS.

*7 p.m.* Council Meeting.

*8 p.m.* Ordinary General Meeting. Paper to be read: "On the Chemistry of Secondary Cells," by Prof. W. E. AYRTON, F.R.S., C. G. LAMB, B.Sc., and E. W. SMITH.

The above Paper will be discussed together with that on "The Working Efficiency of Secondary Cells," by the same Authors, which was read at the Edinburgh Meeting on July 16th.

**FRIDAY, November 14th.**

PHYSICAL SOCIETY.

*5 p.m.* Papers to be read: "On Certain Relations existing among the Refraction Indices of some of the Chemical Elements," by Rev. T. PELHAM DALE, M.A.; "Tables of Spherical Harmonics with examples of their practical use," by Prof. J. PERRY, F.R.S.

# The Electrician.

**Published every Friday, Price Fourpence; Post Free, Fourpence Halfpenny.**
**Editorial, Publishing, and Printing Offices:**
**SALISBURY COURT, FLEET ST., LONDON, E.C.**
*Telephone No.* 2714. *Telegrams:* "ELECTRICIAN NEWSPAPER, LONDON."

*All Letters relating to Subscriptions, Advertisements and other business matters should be addressed to the Publisher,* "THE ELECTRICIAN," *Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* "THE ELECTRICIAN" *Printing and Publishing Company, Limited, and be crossed* "*Coutts and Co.*" *All other letters to be addressed to the Editor.*

*All letters intended for insertion in* "THE ELECTRICIAN," *or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever will be taken of anonymous communications.*

"THE ELECTRICIAN" *is published every Friday morning, in time for the morning mails. Subscribers should receive their copies by the first post on Friday morning.*

"THE ELECTRICIAN" *is on sale at the railway bookstalls throughout the Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices as above.*

*New Volumes of* "THE ELECTRICIAN" *commence in May and November.*

## SUBSCRIPTION RATES.

The rates for Subscriptions to "THE ELECTRICIAN" are as follows:—

| | 3 months. s. d. | 6 months. s. d. | 12 months. s. d. |
|---|---|---|---|
| For the United Kingdom | 5 0 | 10 0 | 19 6 |
| For Foreign Parts and Colonies:— Within Postal Union | 6 6 | 12 6 | 24 0 |
| Aden, Borneo, Ceylon, China, India, Japan, Java, Labuan, Mozambique, New Caledonia, Persia, Philippine Islands, Siam, Transvaal, and Zanzibar | 7 6 | 14 6 | 28 0 |

## TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has by far the largest circulation of any English Electrical paper, and circulates all over the World.**

*Particulars relating to Advertisements will be promptly forwarded on application to the Offices as above.*

TRADE ADVERTISEMENTS *intended for the current issue must reach the Offices not later than First Post on Thursday morning. Renewals of expiring advertisement orders and alterations to standing advertisements should be in the Publisher's hands by Wednesday at latest. No alteration can be made in Wrapper advertisements after Wednesday evening.*

SMALL PREPAID ADVERTISEMENTS *(for Rates see page xvii.) are accepted up to 4 p.m. on Thursday.*

## TECHNICAL PRINTING.

"THE ELECTRICIAN" PRINTING AND PUBLISHING COMPANY (LIMITED) *inform Electricians, Electric Light Engineers, &c., that they make a specialty of Technical Printing, and have a large Staff thoroughly acquainted with Electro-Technology. They can, therefore, promise Accuracy and Despatch in the Printing of Electro-Technical Literature, &c.*

## "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. (Royal 8vo.)

*Early in each year is issued* "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. *The* DIRECTORY *was established in 1883, and the 1890 Edition consisted of about 850 pages of printed matter. The names and addresses of all persons engaged in the Electrical Industries at home and abroad may be relied upon as accurate. Useful Tables and Electrical Formulæ, and information specially compiled for this work are given, together with popularly-written Biographical Notices of the leading Electricians, Electrical Engineers, &c., accompanied in many cases by Portraits.*

*Orders for the 1890 issue should be forwarded* AT ONCE *to the Publishing Offices, Salisbury-court, Fleet-street, London, E.C.*

*The 1891 Edition is now preparing, and New Names, &c., can now be received.*

## ELECTRICAL BOOKS AND PUBLICATIONS.

*All Books, Newspapers, and other publications, dealing with Electrical and kindred subjects, can be ordered direct of* "THE ELECTRICIAN" *Printing and Publishing Company, who are proprietors of the well-known* "ELECTRICIAN" *Series of Standard Electrical Works, and are agents for all the leading publishing houses at home and abroad.*

## THE CITY AND SOUTH LONDON RAILWAY.

The construction and equipment of the first electrical railway in this country, which was opened on Tuesday last, naturally divides itself into two portions—the mechanical work of driving the tunnels and making the lifts, and the electrical work of providing for the transmission of the power generated by the engines to the motors which propel the trains. These two portions differ from each other to a somewhat remarkable degree, inasmuch as the former is full of novelties, while the latter is as simple a piece of electrical engineering as can be found. The tunnels were driven on the ingenious GREATHEAD system, which, while it reminds one strongly of the "shield" with which BRUNEL drove the first Thames tunnel, is a bold and skilfully-arranged departure from ordinary practice. The new idea of running one tunnel below another in order to save space, the working of a connected system of immense lifts from one pumping station, the abolition of the ticket system, are among the more important innovations, together with many minor devices, such as the ejector hydrants for draining the tunnel. On the other hand, the electrical engineer, while he cannot but welcome the direct driving of the armatures, a desideratum often talked of but never before realised, will find little, if any, other novelty, either great or small; even the direct driving being an obvious method which is only a novelty, because an opportunity for its use has not previously presented itself. At all events, no ingenious devices are apparent, and on this account but little chance is offered for a

Digitized by Google

breakdown. To achieve an undertaking on such a scale with appliances so simple reflects the highest credit on the engineers concerned. This, the most extensive and important application of the transmission of power, has been carried out with three dynamos of a very well-known type; a switch-board of the utmost simplicity, and one which in this respect may be envied by many an owner of an electric light plant; a steel channel rail on glass insulators, a most unpretentious pair of collectors, a pair of series motors, and a resistance switch; and there you have the whole apparatus. We are not aware that there is any newly patented invention in use, though a large amount of work of a far higher order has been expended, both on the design of the whole scheme and the elaboration of the details. But this absence of elaborate invention is a most satisfactory indication of the state to which electrical engineering has advanced. It is an industry which is scarcely ten years old, and it is no great exaggeration to say that all the electrical apparatus required for this railway might but for its size have been bought from stock, so great is the adaptability of electricity and of electrical machinery. We recently ventured to criticise in a friendly way a system of electric traction, which merits the term "system" since it is an aggregation of ingenious and original inventions, and, as in many "systems" one new departure entails another, the outsider has a difficulty in discovering which features are essential and which are adventitious. The electrical details of the City and South London Railway are so simple that even the *Daily Telegraph* cannot go wrong, though it is unable to put forth an article on the subject without going out of its way to introduce the fairy Electra who "bravely submits to be accumulated, and leaps into the crystal vacuum and glows with cheerful splendour as she circles round the tiny *film* of *platinum*."

It is, we think, highly satisfactory that the first electric railway is no adaptation, but embodies an absolutely fresh departure. Many firms engaged in electric traction and several companies, have from time to time asserted with more or less confidence that they were on the point of entering or had entered into an arrangement with the Metropolitan or with the District Railway Company for running trains, or for working a portion of the lines. In the majority of these cases, it is probable that the proposers were not acquainted with the magnitude of their offers, and modestly withdrew after they had ascertained the real facts. There would be a strong temptation to use the present carriages, and to run—or, at all events, to talk about running—trains of the ordinary length. Electric traction has a much better chance at the South London line. Here the trains will carry a hundred passengers; and 20 trains can run in the hour, even if the two-minute service, which is being talked about, is not feasible. In speed, they can easily outrun the ponderous trains on the Inner Circle; and probably the system of filling and emptying the cars of passengers will give the new line a greater advantage. The earliest railways were sadly fettered by the traditions of the stage-coach; and until these were shaken off, and it was realised that the change was something more than the exchange of horses for a steam locomotive, not much progress was made. Should the new railway prove to be a success, the projected line under Oxford-street is sure to be constructed. When that in its turn has given satisfactory evidence that the right system has been adopted, the alteration of the Metropolitan and possibly of the District Railway must be only a matter of time.

But a work of this kind, though it be all that an engineer can ask for, and on this very account incapable of any fundamental improvement, may for all that fail to be a financial success. The first Thames tunnel was practically a failure as a footway, though a triumph as a work of engineering. *The Times* of Tuesday discusses the probabilities of a 5 per cent. dividend, and does not do so in the prospectus writer's style. The one fare of twopence is, fortunately, a matter which can at any time be altered. It is not improbable that it will reduce the traffic at the intermediate stations, but it may make the calculation of the cost of running rather difficult to compare with other railways. We very much regret to hear that Messrs. Mather and Platt have contracted to run the trains at 3½d. per train mile for two years. This system has proved disastrous in both electrical and other mechanical tramway work, it has led to all sorts of complications and disputes, and has created antagonism where co-operation is essential. The local authorities themselves have not done as much harm to the development of electric traction as have tramway companies, who have tempted inexperienced inventors to make what they call demonstrations of their systems under this method of contracting at so many pence per car mile.

The selection of the standard gauge of 4ft. 8½in. is very satisfactory. It is impossible to tell how our railway systems may develop, and in the event of a serious strike, or a siege, internal communication by means of railways such as this, and the others which may be expected to follow, would be of incalculable value if they could on such emergencies be connected with the main lines. The adoption of the Westinghouse brake is another sensible feature. No doubt an electrical brake would pull up the train quite as promptly, but the failure of the current in the conductor is remotely possible, and the air brake entails a very small expense in working. There is one point only which we wish to criticise, and that is, the insulation resistance of the line. We could hardly believe it when we learned that a leakage of one ampere was calmly contemplated from the point of view of the horse-power lost. In closed iron tubes, and with continuous currents, the effect on telephones and telegraphs is not likely to be serious. The flat glass insulators and the proximity of the conductor to the return rails will easily account for this low insulation, but it seems to be scarcely in keeping with the high-class execution and admirable design of the rest of the undertaking.

## ELECTRICAL DISTRIBUTION BY TRANSFORMERS FROM CENTRAL AND ECCENTRIC STATIONS.*

BY DR. J. A. FLEMING, M.A.

*(Continued from page 711.)*

§ 18. **The Lowrie-Hall System.**—The various elements in the Transformer system of the House-to-House Electric Lighting Company have been brought to their present perfection by the inventive skill of Mr. W. Lowrie and Mr. C. J. Hall. The Alternator built by Messrs. Elwell-Parker, of Wolverhampton, is of a somewhat similar type to the Alternator of Messrs. Zipernowsky Déri and Blathy, employed in the Ganz system. In this machine the stationary portion is the armature in which the current is generated, and the revolving portion constitutes the field magnets. Fig. 51 shows the general external appearance of the 100-unit size machine having a safe out-put of 100,000 watts, or 130 horse-power. The circular iron frame is composed of thin sheets of charcoal iron ring-shaped, insulated from each other by paper and bolted together. This armature ring is parted on the central horizontal line so that the upper part can be lifted off to insert or remove the field magnets. This ring-frame is carried on the cast-iron frame work of the machine, but is insulated from it. On the inner cylindrical surface of this ring-shaped iron core are fixed the armature coils. These coils are formed of copper tape, each wound on a former so as

* All rights are reserved.

Digitized by Google

to form a coil of flat or link shape, and yet slightly curved so as to fit closely to the inner surface of the armature core. The edges of the tape winding are thus exposed. The centre of the flat coil is occupied by a piece of insulating material. These flat coils are placed close together upon the cylindrical inner surface of the divided iron armature ring so that the axis of each coil is radial to the ring, and the coils are secured in their places by strips of wood screwed to the cheeks and extended over the ends of the coils outside the line of travel of the magnets.

These armature coils are then joined up in series, and the terminal wires brought to insulated terminals on a sheet of ebonite contained in a lock-up box. There are 28 armature coils thus joined in series, each coil producing about 70 volts, or 2,000 in all.

The armature coils can be easily individually removed for examination or for repair. The field magnet or revolving portion of the machine consists of a solid soft wrought-iron ring, with wrought-iron radial pole pieces securely attached thereto; and these pole pieces are of solid wrought iron.

The exciting coils are wound on shells, which are slipped on to which is secured the wrought iron ring with the magnet poles. The shaft carries two gun-metal rings insulated from each other and from the shaft to which are attached the ends of the field-magnet circuits, and by means of which the exciting current is passed into the field circuit. Each ring is provided with two sets of brushes, each set being ample for collecting the exciting current, and the brushes and their holders are carried by a support from the base plate. Suitable adjustable springs control the pressure of these brushes, and their holders are carried against their contact rings. The shaft carries two pulleys of cast iron, one, the driving pulley, turned with seven grooves for seven $1\frac{1}{2}$in. ropes, and the other turned with four grooves for four $\frac{3}{4}$in. ropes for driving the exciter dynamo. The exciter is a series-wound machine, with drum armature, running a speed of 800 revolutions per minute. Each alternator has its own exciter, and for the 100 unit alternators the exciters furnish a current of 25 to 28 amperes at 120 volts.

The speed of the alternators is 350 revolutions per minute, giving an alternating current having about 10,000 alternations per minute, or a "frequency" of 83.

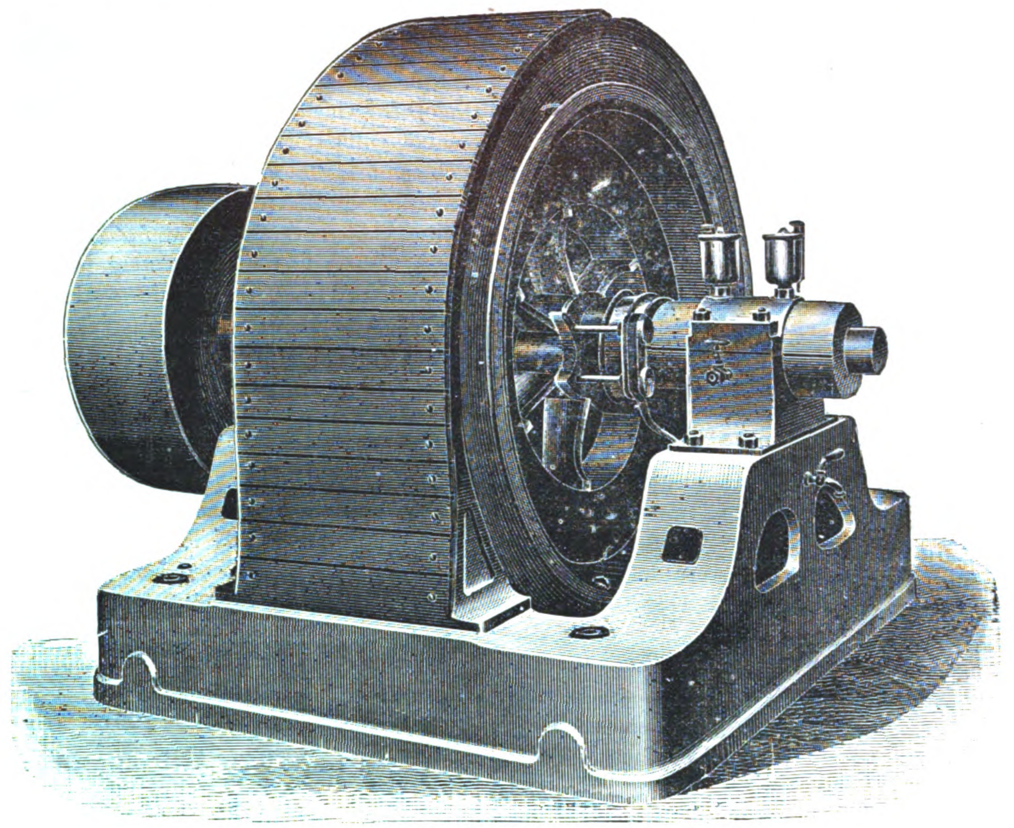

FIG. 51.—100-Unit Lowrie-Hall-Parker Alternator.

these pole pieces, and secured by bolts from being displaced by centrifugal action. There are 28 such radial magnetic poles, alternately N and S polarity.

The coils of the field magnets are joined up in series, and the terminal wires are brought to two insulated gun metal rings on the steel shaft of the dynamo.

The current density in both armature coils and field magnet coils is not allowed to exceed 2,000 amperes per square inch of section.

The base plate of the dynamo is of strong box pattern, ribbed and flanged. The frame for supporting the laminated iron armature core is cast separate, and securely bolted to planed facings. The plummer blocks for the bearings are cast separate from the base plate, and secured thereto by bolts and lugs and wrought iron wedge keys. The bearings of the magnet shaft are each 20in. long and fitted with brasses of phosphor bronze. The bottom brass is so arranged that it can be removed without lifting the shaft and yet well secured sideways. The bearings are provided at each end with oil catchers, by which used oil is caught and drained away to a tank in the base plate, from which it can be drawn off and filtered for re-use. The steel shaft carried by these bearings is 6in. in diameter. It carries a cast iron hub to

The output of each alternator is 50 amperes at 2,000 volts. The over-all height of this alternator is 8ft. 6in., and the weight 10 tons. A separate pair of wires are taken off one coil of the armature for the purpose of regulation of electromotive force in a way to be presently described.

The commercial efficiency of this alternator at full load is stated to be about 85 or 87 per cent. These alternators work well in parallel. If two alternators driven by separate engines are thrown in parallel and the steam is shut off one engine, it still continues to be taken round by its dynamo acting as a motor and driven by the fellow-dynamo acting as a generator.

Alternators of this type are made in the following sizes:—

| Safe output in kilowatts. | Load in 60-watt lamps. | Revolutions per minute. | Revolutions of exciter per minute. |
|---|---|---|---|
| 30 | 500 | 600 | 1,000 |
| 45 | 750 | 550 | 1,000 |
| 60 | 1,000 | 500 | 1,000 |
| 90 | 1,500 | 400 | 800 |
| 120 | 2,000 | 350 | 700 |
| 150 | 2,500 | 300 | 600 |
| 200 | 3,300 | 250 | 500 |

Digitized by Google

All these machines are arranged to give an alternating current having 10,000 to 12,000 reversals of current per minute, and electromotive force of 1,000, 2,000, or 3,000 volts, as required.

§ 19. **Lowrie-Hall Transformers.**—The transformers are of the closed magnetic-circuit core type. Two iron cores are formed of piles of thin iron plates (*see* Fig. 52), each plate being separated by thin paper from the next. On each of these cores is wound a primary and a secondary coil one over the other, part of the iron core projecting beyond the coils at both ends. The two coil-covered cores are then placed side by side, and the plates of the cores projecting beyond the coils are turned over alternately, each pair of plates forming a closed magnetic circuit. The whole of the plates are then clamped tightly together at both ends to ensure good magnetic contact. The completed converter shown in Fig. 53 thus seems to form a closed laminated iron ring of rectangular shape, and having a primary and secondary coil wound on each side of the ring. The transformers are placed in iron-converter cases (Fig. 54). The pairs of primary and secondary coils are respectively joined up in series, and the terminals brought to insulated terminals outside the case. The usual primary and secondary double-pole fuses are placed in porcelain boxes on the case. The converter cases have lugs and rings so as to suspend or fix them in place. These transformers are said to take about ·02 ampere-current in the primary when on open secondary circuit. The various sizes used are for out-puts of 1, 2, 4, 6, 8, 10, 16, 20, 30, 40 E.H.P., and are wound to convert from 2,000, 1,500, and 1,000 volts to 100 or 50 volts.

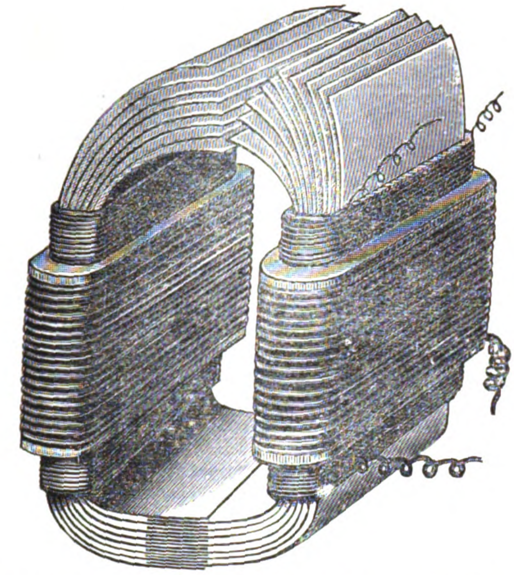

Fig. 52.– Diagram showing Method of building up the Lowrie-Hall Transformer.

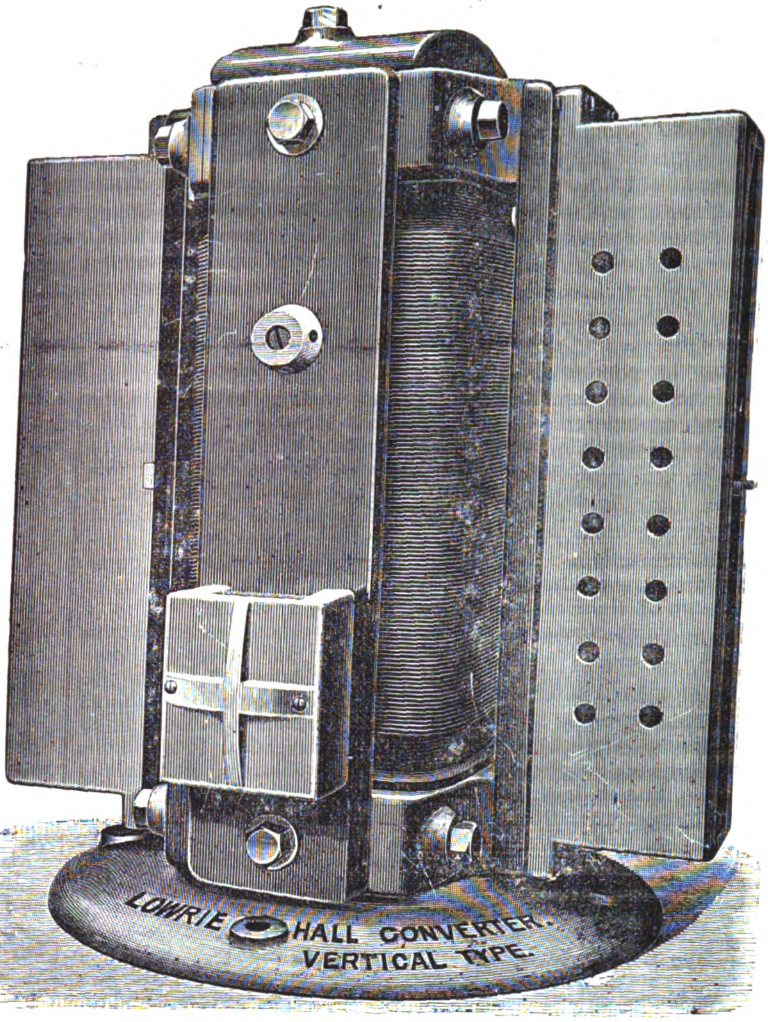

Fig. 54.—Lowrie-Hall Transformer.

*(To be continued.)*

## THE ELECTROLYTIC PREPARATION OF BLEACHING AGENTS.*

BY A. RIGAUT.

The fact that bleaching agents could be obtained by electrolysis of the chlorides has been known for some time. Becquerel[1] calls attention to the fact that chlorine and sodium are products of the decomposition of sodium chloride by the current from a battery of 30 cells. Brand[2] asserts that in 1820 he had suggested the idea of bleaching by the electrolysis of a solution of sea salt, and the experiment which he described is a very curious one. He applied a small disc of platinum, which had been rendered electro-positive to a piece of coloured calico, impregnated with a solution of sodium chloride, and which was stretched upon a second disc, rendered electro-negative. White patches resulted at the parts electrolysed. Brand added that this application had been patented by Bagg. In 1849 Bouis,[3] taking up the experiments of Kolb, who had succeeded in transforming by electrolysis a solution of potassium chloride into chlorate discovered that with the same number of cells the resulting reactions were different, according to the temperature at which he worked, and that if matters were arranged so that the temperature was not raised, hypochlorite of potassium and not chlorate was obtained. This experiment, however, he repeated with more or less concentrated solutions and with different currents the action of which was prolonged for 48 hours, and he always obtained hypochlorite of potassium. The mechanism of its formation is due to the action of the chlorine liberated at the anode upon the nascent potassium at the cathode, the latter arising from the reaction of liberated potassium upon the water of the solution. Since then C. Watt[4] (1851), Hunter (1857), De Gemini[5] (1858) have described electrolytic processes for the production of alkaline hypo-chlorites. In 1859 Lardenois patented a product "electro-chlorygen" obtained by the electrolysis of salt in a lead vat, which formed the negative pole, the positive pole being a sheet of platinum. It is still the electrolysis of the chlorides, with a view of obtaining sodium and chlorine, that Dickson, in 1862, was working at. At the time that these various processes were patented electrolytic methods were practically inapplicable, and we doubt if they were even tried by the chemical industry.

In more recent times we have the patent of Fitzgerald and Molloy (1862). These gentlemen also obtained hypochlorites from chlorides, and pointed out a method of regenerating by electrolysis the hypochlorite exhausted in a bleaching process. The next patent we come to is that of Fournier (1879). A little later (1882) Ostersetzer investigated the electrolysis of a solution of sodium chloride, and showed that when dilute it only gave hydrogen and oxygen, while after a certain degree of concentration had been reached, sodium hypochlorite[6] was obtained. Upon this work, Dobbies and Hutchinson based a method of bleaching by electricity.[7] In 1883 MM. Naudin and Bidet took up the question of electro-chemical bleaching,[8] and endeavoured with the aid of M. Schneider to apply it commercially. These gentlemen showed that in the electrolysis of sodium chloride, taking into consideration the losses inherent to any commercial process, one ought to be able to make the same quantity of chlorine serve indefinitely, "the chlorine on coming into contact with organic matter being transformed into a compound substance containing an exactly equivalent amount of chlorine, and capable of yielding it up." In short, they showed that the chlorine could be regenerated after having acted upon the coloured substance. The laboratory experiments of MM. Naudin and Bidet were very successful, but the inventors, badly informed perhaps, as to the efficiency of the modern dynamo-electric machine, did not devote themselves to the solution of the many difficulties which crop up when a process is made use of commercially, and on a large scale, and they soon gave up the research. In 1883, when M. Naudin published his results, electric bleaching was, it is asserted, well known in Russia,[9] where Lidoff and Tikcomiroff[10], seeking to find the liquid possessing the maximum bleaching power, electrolysed various chlorides. These investigators gave the preference to chloride of potassium. Representing the bleaching properties of an electrolysed solution of potassium chloride by 100, that of sodium chloride was found to be 73, and that of calcium chloride 24. Lidoff and Tikhomiroff also, it seems[11], carried out electric bleaching at the Vienna Electrical Exhibition. According to M. Gimé[12], the production of hypochlorites by electrolysis has, for some time past, been carried out in America, and a concentrated solution of sea-salt is there generally employed. In France, however, we think we are not wrong in stating that, with the exception of M. Hermite, who generates bleaching agents for a special purpose, all the users of hypochlorites still employ chemical processes. In fact, at the Centenary Exhibition, the electro-chemical industry was only represented by the Hermite process and by that of MM. Gall and de Montlaur for manufacturing potassium chlorate.

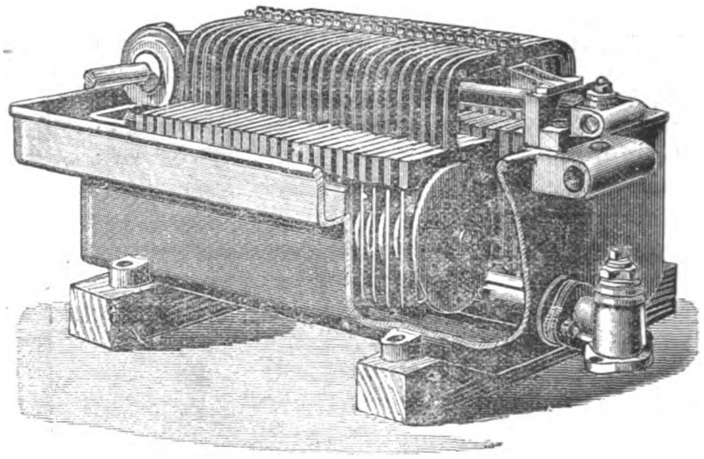

FIG. 1.—Hermite Electrolyser.

It was in 1883, after the failures of M. Naudin, that M. Hermite was led to take up the subject of the electrolysis of the chlorides. After prolonged experiments on sodium chloride, he relinquished this substance, firstly, for calcium chloride, and then for magnesium chloride, the latter salt, in his opinion, lending itself best to transformation into a bleaching agent.

In the Hermite process, the "electrolyser" (Fig. 1) is of galvanised cast iron. Along the bottom runs a pipe, pierced with numerous holes, by means of which the solution enters the vat. A channel runs along the upper edge of the "electrolyser," into which the electrolysed solution overflows and finds its way to the bleaching vats. The cathodes consist of a series of zinc discs mounted on two slowly rotating spindles. Between each pair of discs is an anode plate (Fig. 2) consisting of platinum gauze fixed in an ebonite frame and connected by a leaden lug to a copper bar. In order to keep the zinc discs perfectly clean, flexible ebonite scrapers, such as the one shown in Fig. 2, are fixed to the anodes. As the zinc discs revolve, these ebonite pieces bear against their surfaces and clear off any deposit. In carrying out operations on a large scale, several "electrolysers" are connected in series. Generally speaking, a current of from 1,000 to 1,200 amperes at a pressure of five volts is employed.

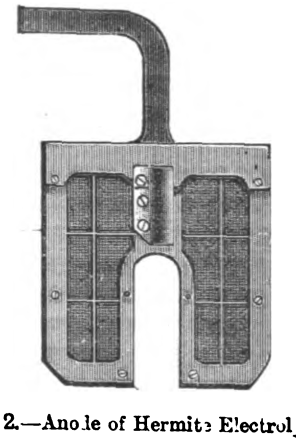

FIG. 2.—Anode of Hermite Electrolyser.

From the point of view of economy the anode should be a good conductor, cheap, and unattacked by the products of electrolysis. Carbon seems, therefore, to be the most suitable substance for this purpose, and in many processes it has been and is employed. M.

Hermite, however, after lengthy experiments, failed to obtain a grade of carbon proving sufficiently unattackable by electrolysed chlorides. He found that carbon oxidised and disintegrated. The classical researches of Bartoli and Pasogli (1882) showed that whenever in electrolysis oxygen was liberated at the anode, carbon is attacked, and we have as a result carbonic oxide, carbonic acid, and a black substance "mellogen," etc., and, in the case of graphite, graphitic acid. According to the same investigators, when chloride solutions are electrolysed the disintegration of the retort carbon employed is the more rapid the more dilute the solutions. Since, therefore, in the Hermite process the magnesium chloride solution is extremely weak, platinum anodes become absolutely necessary, and this renders the "electrolysers" costly, and tends to prevent the general adoption of the process in "*la petite industrie.*" M. Hermite has endeavoured to make use of platinised copper and porcelain, but the platinum was rapidly attacked by the electrolysed solution.

Up to the present M. Hermite has employed a 5 per cent. solution of magnesium chloride, but he now proposes to use a more economical bath. After having tried with some success a solution of Strassfurt "camallite," which is a double chloride of magnesium and potassium, he now makes use of a solution containing 5 per cent. of magnesium chloride and 5 per cent. of sea salt, a small quantity of recently precipitated magnesia being added to the bath. When this solution is electrolysed, only the water and the magnesium chloride appear to be decomposed; the solution, in fact, remains perfectly clear, and if the sodium chloride were electrolysed, soda would be formed and magnesia precipitated, and the liquid would be clouded.

The interpretation of the various chemical reactions which take place during the electrolysis of the chlorides is difficult, though the formation of hypochlorites by the action of the chlorine liberated at the + pole upon the alkali generated at the − pole seems a probable explanation. This does not, however, explain the great bleaching power of the solution, which bears no relation to the amount of chlorine it contains. This apparently abnormal property may be explained, if not proved, somewhat as follows:—The water is decomposed at the same time as the chloride, ozonised oxygen being formed. Now, ozone, as Dr. Graf pointed out some few months ago, is fairly soluble in the alkaline chlorides, and especially so in magnesium chloride. Again, electrolytic ozone is a well-known bleaching agent, and H. N. Warren[13] tried to make use of it in his method of bleaching by the electrolysis of water. Among the products which might be formed is oxygenated water, whose absence, however, in the electrolysed solutions of the chlorides has been noted, but which would, if present, be able to act as a bleaching agent; indeed, quite recently a method of bleaching cotton based on its properties has been described.[14] But oxygenated water being absent, we can predict the presence of other bleaching agents in the liquid. M. Dutet[15] has, in fact, observed that in the electrolysis of alkaline solutions the volume of the oxygen which is liberated is much less than one-half of that of the hydrogen. The properties of the liquid obtained were investigated by M. Dutet, who came to the conclusion that alkaline peroxides, endowed with oxidising powers, are formed, whose instability has, up to the present, prevented their isolation. Now these unstable peroxides may be bleaching agents, and we note that one of the conditions of the electrolysis of the chlorides is the alkalinity of the liquid, potash or soda for the alkaline chlorides, magnesia in the case of the Hermite process. Let us add to this hypothesis the far more probable one of the formation of unknown oxygen chlorine compounds, for the chemistry of these compounds is still very obscure. It is, indeed, possible that there may be some sort of incompatibility between the formation of all these products by electrolysis of the chlorides. For instance, it is well known that ozone is rapidly destroyed in the presence of chlorine; but what is the resultant body, and what are its bleaching qualities? MM. Hautefeuille and Chappins endeavoured to obtain it by means of high-tension electric discharges in a mixture of oxygen and chlorine[16]. In 1887 the brothers Brin proposed to use the bleaching properties of this mixture after its passage through their "ozoniser" to bleach paper pulp[17]. Mailfert asserts that chlorine and ozone combine to form chloric acid[18]. E. Becquerel[19] made an experiment which showed that an oxygen compound of chlorine should result from the electrolysis of the chlorides, even without the presence of alkalies. Becquerel placed in the same circuit some acidulated water and an aqueous solution of chlorine, and found that while 7·25 volumes of oxygen were liberated from the water, only 6·25 were liberated from the chlorine solution. The same experiment with bromium and iodine gave respectively 4·5 and 4 volumes. Electrolytic oxygen is, therefore, capable of combining with chlorine. M. Riche, who has also studied this question, has shown that the final product of the electrolysis of an aqueous solution of chlorine is perchloric acid.[20]

## THE ELECTRO-MAGNET.*

BY PROF. SILVANUS P. THOMPSON.

(*Continued from page 751.*)

### APPENDIX TO LECTURE II.

CALCULATION OF EXCITATION, LEAKAGE, &c.

*Symbols used.*

$N$ = whole number of magnetic lines (C.G.S., definition of magnetic lines, being 1 line per square centimetre to represent intensity of a magnetic field, such that there is 1 dyne on unit magnetic pole) that pass through the magnetic circuit. Also called the *magnetic flux*.
$B$ = the number of magnetic lines per square centimetre, in the iron; also called the *induction*, or the internal magnetisation.
$B''$ = the number of magnetic lines per square inch in the iron.
$H$ = the magnetic force or intensity of the magnetic field, in terms of the number of magnetic lines to the square centimetre that there would be in air.
$H''$ = the magnetic force, in terms of the number of magnetic lines that there would be to the square inch, in air.
$\mu$ = the *permeability* of the iron, &c.; that is, its magnetic conductivity or multiplying power for magnetic lines.
$A$ = area of cross section, in square centimetres.
$A''$ = area of cross section, in square inches.
$l$ = length in centimetres.
$l'$ = length, in inches.
$S$ = number of spirals or turns in the magnetising coil.
$i$ = electric current, expressed in amperes.
$v$ = coefficient of allowance for leakage; being the ratio of the whole magnetic flux to that part of it which is usefully applied. (It is always greater than unity.)

RELATIONS OF UNITS.

1 inch = 2·54 centimetres;
1 centimetre = 0·3937 inch.
1 square inch = 6·45 square centimetres;
1 square centimetre = 0·1550 square inch;
1 cubic inch = 16·39 cubic centimetres;
1 cubic centimetre = 0·0610 cubic inch.

TO CALCULATE THE VALUE OF B OR OF B″ FROM THE TRACTION.

If P denote the pull, and A the area over which it is exerted, the following formulæ (derived from Maxwell's law), may be used:—

$$B = 4{,}965 \sqrt{\frac{P \text{ kilos.}}{A \text{ sq. cm.}}};$$

$$B = 1{,}316{\cdot}6 \sqrt{\frac{P \text{ lb.}}{A \text{ sq. in.}}}; \text{ or}$$

$$B'' = 8{,}494 \sqrt{\frac{P \text{ lb.}}{A \text{ sq. in.}}}.$$

TO CALCULATE THE REQUISITE CROSS-SECTION OF IRON FOR A GIVEN TRACTION.

It is not expedient to attempt to employ tractive forces exceeding 150lb. per square inch in magnets whose cores are of soft wrought iron, or exceeding 28lb. per square inch in cast iron. Dividing the given load that is to be sustained by the electro-magnet by one or other of these numbers, gives the corresponding requisite sectional area of wrought or cast iron respectively.

TO CALCULATE THE PERMEABILITY FROM B OR FROM B″.

This can only be satisfactorily done by referring to a numerical Table (such as Table II. or IV.), or to graphic curves (such as Fig. 18), in which are set down the result of measurements made on actual samples of iron of the quality that is to be used. The

* A series of four Cantor Lectures delivered before the Society of Arts, January—February, 1890.

Digitized by Google

values of $\mu$ for the two specimens of iron to which Table II. refers may be *approximately* calculated as follows :—

$$\text{For annealed wrought iron, } \mu = \frac{17{,}000 - B}{3 \cdot 5};$$

$$\text{For grey cast iron, } \mu = \frac{7{,}000 - B}{3 \cdot 2}.$$

These formulæ must not be used for the wrought iron for tractions that are less than 28lb. per square inch, nor for cast iron for tractions less than $2\frac{1}{4}$lb. per square inch.

### To Calculate the Total Magnetic Flux which a Core of given Sectional Area can conveniently carry.

It has been shown that it is not expedient to push the magnetisation of wrought iron beyond 100,000 lines to the square inch, nor that of cast iron beyond 42,000. These are the highest values that ought to be assumed in designing electro-magnets. The total magnetic flux is calculated by multiplying the figure thus assumed by the number of square inches of sectional area.

### To Calculate the Magnetising Power requisite to force a given Number of Magnetic Lines through a definite Magnetic Reluctance.

Multiply the number which represents the magnetic reluctance by the total number of magnetic lines that are to be forced through it. The product will be the amount of magnetomotive force. If the magnetic reluctance has been expressed on the basis of centimetre measurements, the magneto-motive force, calculated as above, will need to be divided by 1·2566 $\left(i.e., \text{by } \frac{4\pi}{10}\right)$ to give the number of ampere-turns of requisite magnetising power. If, however, the magnetic reluctance has been expressed in the units explained below, based upon inch measures, the magnetising power, calculated by the rule given above, will already be expressed directly in ampere-turns.

### To Calculate the Magnetic Reluctance of an Iron Core.

(*a*) *If Dimensions are given in Centimetres.*—Magnetic reluctance being directly proportional to length, and inversely proportional to sectional area and to permeability, the following is the formula :—

$$\text{Magnetic reluctance} = \frac{l}{A\mu};$$

but the value of $\mu$ cannot be inserted until one knows how great B is going to be ; when reference to Table II. gives $\mu$.

(*b*) *If Dimensions are given in Inches.*—In this case we can apply a numerical co-efficient, which takes into account the change of units (2·54), and also, at the same time, includes the operation of dividing the magneto-motive force by four-tenths of $\pi$ (=1·2566) to reduce it to ampere turns. So the rule becomes

$$\text{Magnetic reluctance} = \frac{l''}{A''\mu} \times 0 \cdot 3132.$$

*Example.*—Find the magnetic reluctance from end to end of a bar of wrought-iron 10in. long, with a cross section of four square inches, on the supposition that the magnetic flux through it will amount to 440,000.

### To Calculate the Total Magnetic Reluctance of a Magnetic Circuit.

This is done by calculating the magnetic reluctances of the separate parts, and adding them together. Account must, however, be taken of leakage ; for when the flux divides, part going through an armature, part through a leakage path, the law of shunts comes in, and the net reluctance of the joint paths is the reciprocal of the sum of their reciprocals. In the simplest case the magnetic circuit consists of three parts (1) armature, (2) air in the two gaps, (3) core of the magnet. These three reluctances may be separately written, as in the table in following table.

If the iron used in armature and core is of the same quality, and magnetised up to the same degree of saturation, $\mu$ and $\mu_3$, will be alike. For the air-gaps $\mu = 1$, and therefore is not written in.

If there were no leakage, the total reluctance would simply be the sum of these three terms. But when there is leakage, the total reluctance is reduced.

| — | For Centimetre Measure. | For Inch Measure. |
|---|---|---|
| 1. Armature ............... | $\frac{l}{A_1 \mu_1}$ | $\frac{l''_1}{A''_1 \mu_1} \times 0 \cdot 3132$ |
| 2. The Gaps ............... | $2\frac{l_2}{A_2}$ | $2\frac{l''_2}{A''_2} \times 0 \cdot 3132$ |
| 3. Magnet Core............ | $\frac{l_3}{A_3 \mu_3}$ | $\frac{l''_3}{A''_3 \mu_3} \times 0 \cdot 3132$ |

### To Calculate the Ampere-Turns of Magnetising Power Requisite to Force the Desired Magnetic Flux through the Reluctances of the Magnetic Circuit.

(*a.*) *If Dimensions are given in Centimetres* the rule is :—

Ampere-turns = the magnetic flux, multiplied by the magnetic reluctance of the circuit, divided by $\frac{4}{10}$ of $\pi$ (=1·2566).

Or, in detail, the three separate amounts of ampere-turns required for three principal magnetic reluctances are explained as follows :—

$$\left.\begin{array}{l}\text{Ampere-turns required to drive N lines}\\ \text{through iron of armature} \ldots\ldots\end{array}\right\} = N \times \frac{l_1}{A_1 \mu_1} \div \frac{4\pi}{10},$$

$$\left.\begin{array}{l}\text{Ampere-turns required to drive N lines}\\ \text{through the two gaps} \ldots\ldots\end{array}\right\} = N \times \frac{2l_2}{A_2} \div \frac{4\pi}{10},$$

$$\left.\begin{array}{l}\text{Ampere turns required to drive } v\text{N lines}\\ \text{though the iron of magnet core} \ldots\ldots\end{array}\right\} = vN \times \frac{l_3}{A_3 \mu_3} \div \frac{4\pi}{10},$$

And, adding up : —

$$\text{Total ampere-turns required} \ldots\ldots = \frac{10}{4\pi} N \left\{ \frac{l_1}{A_1 \mu_1} + \frac{2l_2}{A_2} + \frac{v\, l_3}{A_3 \mu_3} \right\}.$$

(*b.*) *If Dimensions are given in Inches*, the rule is :—Ampere-turns = magnetic flux multiplied by the magnetic reluctance of the circuit. Or, in detail :—

$$\left.\begin{array}{l}\text{Ampere-turns required to drive N lines}\\ \text{through iron of armature} \ldots\ldots\end{array}\right\} = N \times \frac{l''_1}{A''_1 \mu_1} \times 0 \cdot 3132,$$

$$\left.\begin{array}{l}\text{Ampere-turns required to drive N lines}\\ \text{through two gaps} \ldots\ldots\end{array}\right\} = N \times \frac{2\, l''_2}{A''_2} \times 0 \cdot 3132,$$

$$\left.\begin{array}{l}\text{Ampere-turns required to drive } v\text{N lines}\\ \text{through iron core of magnet} \ldots\ldots\end{array}\right\} = vN \times \frac{l''_3}{A''_3 \mu_3} \times 0 \cdot 3132;$$

And, adding up :—

$$\text{Total ampere turns required} = 0 \cdot 3132\, N \left\{ \frac{l''_1}{A''_1 \mu_1} + \frac{2\, l''_2}{A''_2} + \frac{v\, l''_3}{A''_3 \mu_3} \right\}.$$

It will be noted that here $v$, the coefficient of allowance for leakage, has been introduced. This has to be calculated as shown later. In the meantime it may be pointed out that, in designing electro-magnets for any case where $v$ is approximately known beforehand, the calculation may be simplified by taking the sectional area of the magnet core greater than that of the armature in the same proportion. For example, if it were known that the waste lines that leak were going to be equal in number to those that are usefully employed in the armature (here $v = 2$), the iron of the cross might be made of double the section of that of the armature. In this case $\mu_3$ will approximately equal $\mu_1$.

### To Calculate the Coefficient of Allowance for Leakage, $v$.

$v$ = total magnetic flux generated in magnet core ÷ useful magnetic flux through armature. The respective useful and waste magnetic fluxes are proportional to the permeances along their respective paths. *Permeance*, or magnetic conductance, is the reciprocal of the *reluctance*, or magnetic resistance. Call useful permeance through armature and gaps $u$; and the waste permeance in the stray field $w$; then

$$v = \frac{u + w}{u},$$

$w$ may be estimated by the Table VIII. given above, or other leakage rules, but should be divided by two, as the average difference of magnetic potential over the leakage surface is only about half that at the ends of the poles.

### Rules for Estimating Magnetic Leakage.

(I. to III. Adapted from Prof. Forbes' rules.)

*Prop. I. Permeance between two parallel areas facing one another.*—Let areas be $A_1''$ and $A_2''$ square inches, and distance apart $d''$ inches, then :—

$$\text{Permeance} = 3 \cdot 193 \times \tfrac{1}{2} (A''_1 + A''_2) \div d''.$$

*Prop. II. Permeance between two equal adjacent rectangular areas lying in one plane.*—Assuming lines of flow to be semicircles, and that distances $d''_1$ and $d''_2$ between their nearest and furthest edges respectively are given, also $a''$ their width along the parallel edge :—

$$\text{Permeance} = 2 \cdot 274 \times a'' \times \log_{10} \frac{d_2''}{d_1}.$$

*Prop. III. Permeance between two equal parallel rectangular areas lying in one plane at some distance apart.*—Assume lines of leakage to be quadrants joined by straight lines.

$$\text{Permeance} = 2 \cdot 274 \times a'' \times \log_{10} \left\{ 1 + \frac{\pi (d'_2 - d_1)}{d''_1} \right\}.$$

Digitized by Google

*Prop. IV. Permeance between two equal areas at right angles to one another.*—Permeance (if air angle is 90°) = double the respective value calculated by II. or III.

Permeance (if air angle is 270°) = $1\frac{2}{3}$ times the respective value calculated by II.

If measures are given in centimetres these rules become the following:—

$$\text{I. } \tfrac{1}{2}(A_1 + A_2) \div d;$$

$$\text{II. } \frac{a}{\pi} \log_e \frac{d_2}{d_1};$$

$$\text{III. } \frac{a}{\pi} \log_e \left(1 + \frac{\pi(d_2 - d_1)}{d_1}\right).$$

*Prop. V. Permeance between two parallel cylinders of indefinite length.*—The formula for the reluctance is given above: the permeance is the reciprocal of it. Calculations are simplified by reference to Table VIII.

---

I have now to make a few remarks before entering upon the consideration of special forms of magnets. I have already pointed out that where you require a magnet simply for holding on to its armature, common-sense (in the form of our simplest formula) dictated that the circuit of iron should be as short as was compatible with getting the required amount of winding upon it. That at once brings us to the question of the difference in performance of long magnets and short ones. Last week we treated that topic so far as this, that if you require your magnet to attract over any range across an air space, you required a sufficient amount of exciting power in the circulation of electric current to force the magnetic lines across that resisting space, and therefore you required length of core in order to get the required coil wound upon the magnetic circuit. But there is one other way in which the difference of behaviour between long and short magnets—I am speaking of horse-shoe shapes—comes into play. So far back as 1840, Ritchie found that it was more difficult to magnetise steel magnets (using for that purpose electro-magnets to stroke them with) if these electro-magnets were short than if they were long. He was, of course, comparing magnets which had the same tractive power, that is to say, presumably had the same section of iron magnetised up to the same degree of magnetisation. This difference between long and short cores is obviously to be explained on the same principle as the greater projecting power of the long-legged magnets. In order to force magnetism not only through an iron arch but through whatever is beyond, which has a lesser permeability for magnetism, whether it be an air gap or an arch of hard steel destined to retain some of its magnetism, you require magneto-motive force enough to drive the magnetism through that resisting medium; and, therefore, you must have turns of wire; that implies that you must have length of leg on which to wind those turns. Ritchie also found that the amount of magnetism remaining behind in the soft iron arch after turning off the current, at the first removal of the armature, was a little greater with long than with short magnets; and, indeed, it is what we should expect now, knowing the properties of iron, that long pieces, however soft, retain a little more—have a little more memory, as it were, of having been magnetised—than short pieces. Later on I shall have specially to draw your attention to the behaviour of short pieces of iron which have no magnetic memory.

WINDING OF THE COPPER.

I now take up the question of winding the copper wire upon the electro-magnet. How are we to determine beforehand the amount of wire required, and the proper gauge of wire to employ?

The first stage of such a determination is already accomplished; we are already in possession of the formulæ for reckoning out the number of ampere-turns of excitation required in any given case. It remains to show how from this to calculate the amount of bobbin-space, and the quantity of wire to fill it. Bear in mind that a current of 10 amperes (*i.e.*, as strong as that used for a big arc light) flowing once around the iron, produces exactly the same effect magnetically as a current of one ampere flowing around 10 times, or as a current of only one-hundredth part of an ampere flowing around a thousand times. In telegraphic work the currents ordinarily used in the lines are quite small, usually from five to twenty thousandths of an ampere; hence in such cases the wire that is wound on need only be a thin one, but it must have a great many turns. Because it is thin and has a great many turns, and is consequently a long wire, it will offer a considerable resistance. That is no advantage, but does not necessarily imply any greater waste of energy than if a thicker coil of fewer turns were used with a correspondingly larger current. Consider a very simple case. Suppose a bobbin is already filled with a certain number of turns of wire, say 100, of a size large enough to carry one ampere without over-heating. It will offer a certain resistance, it will waste a certain amount of the energy of the current, and it will have a certain magnetising power. Now suppose this bobbin to be re-wound with a wire of half the diameter, what will the result be? If the wire is half the diameter it will have one quarter the sectional area, and the bobbin will hold four times as many turns (assuming insulating materials to occupy the same percentage of the available volume). The current which such a wire will carry will be one-fourth as great. The coil will offer sixteen times as much resistance, being four times as long and of one-fourth the cross-section as the other wire. But the waste of energy will be the same, being proportional to the resistance and to the square of the current, for $16 \times \frac{1}{16} = 1$. Consequently the heating effect will be the same. Also the magnetising power will be the same, for though the current is only one-quarter of an ampere, it flows around 400 turns; the ampere-turns are one hundred, the same as before. The same argument would hold good with any other numerical instance that might be given. It therefore does not matter in the least to the magnetic behaviour of the electro-magnet whether it is wound with thick wire or thin wire, provided the thickness of the wire corresponds to the current it has to carry, so that the same number of watts of power are spent in heating it. For a coil wound on a bobbin of given volume the magnetising power is the same for the same heat waste. But the heat waste increases in a greater ratio than the magnetising power, if the current in a given coil is increased; for the heat is proportional to the square of the current, and the magnetising power is simply proportional to the current. Hence it is the heating effect which in reality determines the winding of the wire. We must—assuming that the current will have a certain strength—allow enough volume to admit of our getting the requisite number of ampere-turns without overheating. A good way is to assume a current of one ampere while one calculates out the coil. Having done this, the same volume holds good for any other gauge of wire appropriate to any other current. The terms "long-coil" magnet and "short-coil" magnet are appropriate for those electro-magnets which have, respectively, many turns of thin wire and few turns of thick wire. These terms are preferable to "high-resistance" and "low-resistance," sometimes used to designate the two classes of windings, because, as I have just shown, the resistance of a coil has in itself nothing to do with its magnetising power. Given the volume occupied by the copper, then for any current-density (say, for example, a current density of 2,000 amperes per square inch of cross-section of the copper), the magnetising power of the coil will be the same for all different gauges of wire. The specific conductivity of the copper itself is of importance; for the better the conductivity, the less the heat-waste per cubic inch of winding. High conductivity copper is, therefore, to be preferred in every case.

Now the heat which is thus generated by the current of electricity raises the temperature of the coil (and of the core), and it begins to emit heat from its surface. It may be taken as a sufficient approximation that a single square inch of surface, warmed 1°Fahr. above the surrounding air, will steadily emit heat at the rate of $\frac{1}{225}$ of a watt. Or, if there is provided only enough surface to allow of a steady emission of heat at the rate of 1 watt* per square inch of surface, the temperature of that surface will rise to about 225° Fahr. above the temperature of the surrounding air. This number is determined by the average emissivity of such substances as cotton, silk, varnish, and other materials of which the surfaces of coils are usually composed.

In the specifications for dynamo machines it is usual to lay down a condition that the coils shall not heat more than a certain number of degrees warmer than the air. With electro-magnets it is a safe rule to say that no electro-magnet ought ever to heat up to a temperature of more than 100°Fahr. above the surrounding air. In many cases it is quite safe to exceed this limit.

The resistance of the insulated copper wire on a bobbin may be approximately calculated by the following rule. If $d$ is the diameter of the naked wire, in mils., and D is the diameter, in mils., of the wire when covered, then the resistance per cubic inch of the coil will be:—

$$\text{Ohms per cub. inch} = \frac{960{,}700}{D^2 \times d^2}.$$

We are, therefore, able to construct a wire-gauge and amperage table which will enable us to calculate readily the degree to which a given coil will warm when traversed by a given current, or conversely, what volume of coil will be needed to provide the requisite

* The *watt* is the unit of rate of expenditure of energy, and is equal to ten million ergs per second, or to 1-746th of a horse-power. A current of one ampere, flowing through a resistance of one ohm, spends energy in heating at the rate of one watt. One watt is equivalent to 0·24 calories per second of heat. That is to say, the heat developed in one second, by expenditure of energy at the rate of one watt would suffice to warm one gramme of water through 4·2 (Centigrade) degrees. As 252 calories are equal to one British (lb. Fahrenheit) unit of heat, it follows that heat emitted at the rate of one watt would suffice to warm 3·4lb. of water one degree Fahrenheit in one hour; or one British unit of heat equals 1,058 watt-seconds.

Digitized by Google

circulation of current without warming beyond any prescribed excess.

Accordingly, I shall give a Wire-Gauge and Amperage Table which we have been using for some time at the Finsbury Technical College. It was calculated out under my instructions by one of the Demonstrators of the College, Mr. Eustace Thomas, to whom I am indebted for the great care bestowed upon the calculations.

For many purposes, such as for use in telegraphs and electric bells, smaller wires than any of those mentioned in the table are required. The table is, in fact, intended for use in calculating magnets in larger engineering work.

*(To be continued.)*

## AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *October* 21, 1890.

**The Street Railway Convention.**—The event of the past week has been the American Street Railway Convention, at Buffalo, N.Y. To electricians it was particularly interesting, for the reason that every branch of electrical industry was there represented, its representatives outnumbering the Street Railway delegates proper by at least two to one. The Westinghouse Electric Railway Company, which has been working very quietly up to the present time, appeared with one of its motor cars, a particularly elegant specimen, built at the Pullman works, and the new motor was the subject of a great deal of attention on the part of both street railway men and electricians. Little need be added to what has already been published of its peculiarities. In practice it runs admirably, the cast-in gearing somewhat deadening the noise which is only too noticeable in most electric cars. This was not as completely obviated, however, as early reports indicated—the unpleasant whirring was somewhat muffled, but by no means absent. Another interesting electrical exhibit was that of the Wenstrom electric railway system which is now being vigorously exploited. The Wenstrom system uses a four-pole motor of the well-known Wenstrom type, geared but once instead of through an intermediate shaft, as is now usual. The gearing is not rigid, but through the medium of a hydraulic coupling, practically a small rotary pump forcing oil through a closed circuit. The circulation can be regulated or entirely stopped by a valve, so that when the valve is opened, the motor may run free without driving the car axle; but when it is closed, and the oil can no longer circulate, the whole turns as if it were rigidly connected, as indeed it is, through the medium of an incompressible mass of oil. The arrangement is highly ingenious, and is said to work admirably in practice. The first Wenstrom road will be started ere long, and then some further details will be forthcoming. The Edison Company, which is now operating the Sprague apparatus, showed a complete motor truck, equipped with two interesting additions to the Sprague apparatus. The first of these is what is euphemistically known as a starting coil. It is nothing more nor less than a resistance momentarily thrown into series with the motors at the start in order to obviate the initial rush of current. The Edison managers are careful not to call it a resistance coil or rheostat. It is not in any proper sense of the term a rheostat: but it certainly is a resistance coil, although only for temporary use. The second Edison edition to the Sprague system is the equaliser. This is intended to obviate any unequal distribution of current between the two motors, which, as is well known, are placed in parallel. Experience has shown that the load, under certain circumstances, may be very unequally distributed between the pair of motors, and equalising coils have been devised to prevent this. Their action is virtually a sort of compound winding, so that when one motor tends to get more than its share of the work, the increase of current would pass around the field magnets and the other motor, and equalise the load again. It is really a species of cross-compounding between two machines. There seems to be no limit to the number of electric cars to be tried at present. On October 15th, a new Eickemeyer railroad-motor was tested, with a considerable degree of success, which is intended to obviate the necessity for the present gearing, which constitutes a serious objection to our present street-car systems.

NEW YORK, *October* 28, 1890.

**The Westinghouse Arc Light Alternators.**—At the meeting of the Institute of Electrical Engineers, October 21st, a very interesting Paper was read by Messrs. Tobey and Walbridge, dealing with a series of remarkable tests made by them on the alternating arc light dynamo of the Westinghouse Company. This machine, like much of the Westinghouse apparatus, is the invention of Mr. William Stanley, jun., one of our best known and most accomplished experts in alternating current matters. It possesses the very remarkable property of being almost exactly self-regulating, the current of a 40-light arc machine remaining very nearly constant from no load to full lead. This noteworthy result is obtained by the peculiar construction of the armature. This is provided with wide and deep teeth, flaring at the ends so as to partly shut in the space between them. The coils consist of a large number of turns, and are wound around these teeth. The action of the armature as a regulator is accomplished by virtue of its very powerful magnetic reaction. Any tendency to increase the current immediately lowers the potential. So perfectly is this regulation carried out, that the terminals can be short-circuited without the slightest danger; in fact, an automatic short-circuiting switch is provided to avoid the dangerous rise in potential that might be caused by breaking a circuit. The efficiency of this alternator is said to be remarkably high, reaching 90 per cent. on half load, and somewhat higher on full load. Taken altogether, it is a type of dynamo that possesses a very large number of valuable qualities.

**Electrical Execution.**—Another effort is being made to have the electrical execution law repealed, this time in behalf of the miserable Japanese wretch sentenced a few months ago. The present plea is that the execution of Kemmler furnished evidence that death by electricity was a cruel form of capital punishment, and, as such, prohibited by the Constitution of the United States. It is hardly probable, however, that the Supreme Court, before whom this question will come, will take the view of the case desired by the prisoner's attorneys.

**A Substitute for Platinum Wire in Incandescent Lamps.**—The report is current that a chemist near this city has discovered a practical method of dispensing with platinum wire in the manufacture of incandescent lamps. On investigation it appears that this rumour has some substantial foundation. In view of the rapid rise in the price of platinum such a discovery is certainly much to be desired by the public; and it is to be hoped that the inventor will secure the substantial reward that such a discovery merits.

## CORRESPONDENCE.

### THE EDINBURGH EXHIBITION.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Your remarks of last week are calculated to convey an erroneous impression as to the origin and conduct of the Exhibition, a result which I am sure you by no means intend.

No "professional Exhibition promoter" had anything to do with its initiation; in fact, none of the originators had had any connection with previous Exhibitions in any capacity whatever. Mr. Bapty was appointed manager by the Executive Council several months after the start, with which he had absolutely nothing to do. He is the only person favoured with a "dinner and cheque," for which tokens of appreciation he is indebted to the exhibitors alone.

It is clearly inexact to state that "the two representative bodies of the electrical trades and professions gave it no encouragement whatever." On the contrary, the Institution of Electrical Engineers, at a special and full meeting of

Digitized by Google

Council, decided to support the Exhibition, and did so, as a fact, in every way possible. The junior body took a different view, and endeavoured through the three or four members who are reported to have attended the meetings at which the matter was discussed to stop the Exhibition, but in that they altogether failed. Not only was the Exhibition, as a whole, the largest and most varied ever seen in Scotland, but as an electrical Exhibition it was by far the best ever held in the United Kingdom, and is entitled to rank second only to the Paris show of 1881. That the Electrical Section of the London Chamber of Commerce were not unanimous in opposing is shown by the fact that the names of some of its prominent members figure on the London Committee and as exhibitors in the catalogue.

The statement that the chief electrical exhibitors were from the North is also wide of the mark. The great majority of electrical exhibits were from London and France; very few came from Scotland itself. Neither were medals awarded to any electrical exhibits as the paragraph might be read to imply.

The financial results are no doubt disappointing, but are not likely to prove nearly so much so as some of the published statements indicate. The Exhibition was promoted, not to make a profit, but to instruct, educate, and amuse, and in these respects the intentions of the originators have been fully realised.

The almost continuous wet weather experienced during the run of the Exhibition militated much against its financial success, but the chief adverse circumstance, against which it was impossible to contend, was the utter breakdown of the train service on the North British Railway, on which easy access to the Exhibition principally depended. Had this been foreseen or deemed within the bounds of probability, or even possibility, another site would have been chosen or the Exhibition abandoned altogether.—Yours, &c. A. R. BENNETT.

Edinburgh, November 3rd, 1890.

## LOCAL AUTHORITIES AND ELECTRIC TRAMWAYS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR:—No doubt there are Vestries *and* Vestries, but there also are various kinds of schemes for electric tramways submitted to them.

Last week the Chelsea Vestry had submitted to them a scheme by which it was proposed to lay an electric tramway down the main business thoroughfare, and to run cars about 6ft. wide down the centre of a 19ft. 6in. roadway, with shops on each side, where at the present time blocks are constantly occurring during the summer season.

Is it astonishing that the Vestry objected to such a scheme? It is absurd to talk about bribery and bad motives. The ordinary traffic must be given facilities for getting about, and a body of business men know this and must act accordingly.—Yours truly, T. W. E. HIGGENS.

Town Hall, Chelsea, S.W., Nov. 3, 1890.

[We are glad to note that Mr. Higgens, the Surveyor to the Chelsea Vestry, agrees with the opinion expressed in our leader of last week regarding bribery. Considering the present state of the King's-road and of the Fulham-road, the opposition of the Vestry appears to be reasonable.—ED. *E.*]

## ECCENTRIC STATIONS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: When a word already in use has a new meaning assigned to it in scientific language, it is of great importance that that meaning should be carefully defined at the time of its introduction; otherwise the word, instead of saving time, causes confusion.

In the absence of the slightest hint from the author, I concluded—I think, fairly enough—that by central stations he meant generating centres, and by eccentric stations, distributing banks of converters fed from those centres. Thus Deptford would be a central station and the Grosvenor an eccentric; but in one of your Editorial notes to-day I see Deptford described as an "eccentric" station. Might I ask for an authoritative statement as to what is the correct meaning?

While speaking of accuracy, I may mention that the famous lighthouse experiments were conducted at the South and not the North Foreland.—Yours, &c., A. K. C.

[The meaning attached by Dr. Fleming to the term "eccentric station" is, we are authoritatively given to understand, the meaning one would naturally attach to it—viz., *a station which is not at the centre of the area of distribution.* The Deptford Station *is*, therefore, according to Dr. Fleming's use of the term, an "eccentric station."—ED. *E.*]

## LANE FOX CLAIMS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: At a meeting of the Defence Association formed to resist the claims being made by the Lane Fox Electrical Company in respect of the Lane Fox patents, held at the offices of the Kensington and Knightsbridge Electric Lighting Company (Limited), at 148, Brompton-road, S.W., the following resolution was passed:—

"That the list of members of this Association be closed on Saturday fortnight, November 22nd, and after that date members of the electrical trade who, being attacked by the Lane Fox Electrical Company, are desirous of availing themselves of the benefits of this Association, will be required to pay the double fee of £50." Under these circumstances, any members of the trade who wish to join the Association should communicate with me before the above-mentioned date.

I may mention, for the benefit of those who are not fully acquainted with the steps that have been taken in the matter, that several opinions have been obtained and submitted to counsel by different members of the Association, all of which agree in advising that the claims of the Lane Fox Electrical Company cannot be sustained.

Trusting you will be able to insert this in your next issue, as it is most important that it should reach all your readers.—Yours, &c., for the Defence Association,

R. S. ERSKINE, Hon. Sec.

148, Brompton-road, London, S.W., Nov. 4, 1890.

## BOOKS, &c., RECEIVED.

"Proceedings of the American Association for the Advancement of Science, August, 1889." (Salem.)

"Impianti Illuminazione Elettrica." Manuale Praticao di Emilio Piazzoli. (Milano: Ulrico Hoepli.)

"A Treatise on Electro-Metallurgy." By WALTER G. MCMILLAN, (London: Charles Griffin & Co.)

"Electric Light." By John W. Urquhart. 4th Edition. (London: Crosby, Lockwood & Son.)

## TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning.*]

TENDERS INVITED.—The Gas Committee of the Corporation of Nelson are prepared to receive tenders for the supply and erection of an installation capable of supplying electricity for 300 lights. The drawings and specifications may be seen, and all further information obtained, from Mr. Wm. Foster, Engineer's Office, Gas Works, Nelson. Copies of quantities and form of tender may be obtained from the said engineer on deposit of two guineas, which will be returned on receipt of a *bonâ fide* tender. Tenders are to be sent in to Mr. R. M. Prescott, Town Clerk, on or before the 13th inst.

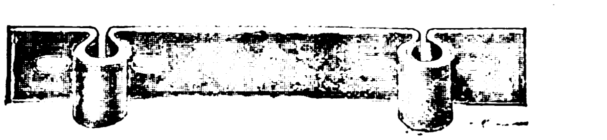
——— Friday, November 28th (not later than two o'clock) is the date fixed for the sending in of tenders for the lighting of the Western District of the City of London. (*See* our issue of October 25th.)

MESSRS. LACOMBE AND CO.—A gold medal has been awarded to Messrs. Lacombe and Co. for their carbon exhibit in the French electrical section of the Edinburgh Exhibition.

Digitized by Google

THE PLANET ENGINEERING COMPANY.—At a meeting held at the Royal Institute of British Architects on Monday last, the Council Room of the Institute was lit by the electric light. The installation at the Institute is being carried out by the above Company, and for the evening a temporary connection was made with accumulators in the Council Room to the satisfaction of the members.

A FIBRE CLEAT.—Messrs. David Moseley and Sons are introducing a cleat made of Celluvert or Kartavert. They are made for



single or for double wires, and are insulating when dry. They are largely used in America, and those who use cleats in this country will find them to be strong and light.

NEW YORK INSULATED WIRE COMPANY.—This Company notify us that they have received a large order for the Grimshaw wires for the Executive Buildings, Washington. They also take pride in having supplied the wire for the Statue of Liberty, the Washington Monument, and the American Departments of War and Navy.

## LEGAL INTELLIGENCE.

### The Halifax and Bermuda Cable Company v. Magniac.

This was an action before Mr. Justice Charles, on Tuesday last, to recover £3,988 and interest, being balance of calls due on Debentures of the Company applied for by the defendant.

Mr. Crump, Q.C., and Mr. Spokes appeared for the plaintiffs; Mr. Haughton for the defendant.

Mr. CRUMP said defendant applied for fifty Debentures of £100 each, in May, 1889, and forty-nine were allotted him; he paid £500 on application and another £500 on allotment, but, applications for the balance being unattended to, after some difficulty an action was commenced by substituted service, the defendant, being abroad, and judgment was signed against him. Afterwards, on the application of the defendant, the judgment was set aside, and a defence was put in to the effect that he had been induced to apply for the Debentures by misrepresentation.

Mr. HAUGHTON said he need not trouble his friend to go into the case at length. The defendant had satisfied himself that the prospectus was issued *bona fide*, and negotiations had been going on with a view to his paying the whole amount due, and the Company abandoning any claim for costs, which he understood was agreed to; but when the friend who had conducted the negotiations said he should like to have the debentures on paying over the money, it appeared that these very debentures which had been allotted to Mr. Magniac, and on the footing of which he was sued, had been deposited by the Company as security for a loan, and the parties with whom they were pledged declined to release them on payment of the amount due on the calls, their claim being somewhat larger on account of interest. He asked, therefore, not making any objection to paying the amount, and even the costs that the money might be paid into court or deposited with someone who would hand it over on receiving the debentures.

Mr. CRUMP said his friend was quite mistaken. When the defendant paid the money the debentures would be handed to him.

Mr. HAUGHTON asked leave to prove what he had stated, but

Mr. JUSTICE CHARLES said such an issue was not raised on the pleadings. He must accept Mr. Crump's statement, and as the only defence raised was abandoned, he must give judgment for the plaintiffs.

### The Edison and Swan Electric Light Company v. Robertson.

This matter came before Mr. Justice Stirling on Tuesday on a motion brought by the plaintiffs for judgment in default of appearance. The statement of claim asked for an injunction to restrain the defendant from further infringing the plaintiff's patent, an order for the delivery up to the plaintiffs of the infringing lamps, and an order for damages. Inasmuch as the plaintiffs had previously established the validity of their patent, they now asked for costs as between solicitor and client. His Lordship made the order as asked.

### Douse's Patent Fire-Check Company.

In this petition, which was brought by Mr. T. J. W. Buckley, for the winding-up of the Company, Mr. Alexander Young, who appeared for the petitioner, stated that he had the consent of the petitioner and of the Company, signed by their respective solicitors, that no order should be made on the petition, except that the costs of the petitioner and of the creditors supporting the petition be taxed and paid. The Company had, as a matter of fact, paid 20s. in the £.—Mr. Justice Stirling acceded to the application.

## COMPANIES' MEETINGS.

### Monte Video Telephone Company (Limited).

The annual ordinary general meeting of this Company was held at the offices, 25, Abchurch-lane, E.C., on the 31st ult., under the presidency of Mr. Arthur Holland.

The SECRETARY (Mr. Edward Johnson) having read the notice calling the meeting,

The CHAIRMAN said that the report was not so satisfactory as they could have desired, and certainly not in accord with the indications held out at the previous meeting, and at others when they were asked to increase the capital of the Company for the purpose of multiple switch boards and other improvements. It was satisfactory, however, in respect of profits, for, as shown in the report, it was about equal to that of last year, and this time they had passed through a period of real depression which was felt both at Monte Video and Buenos Ayres. Although telephones in many cases were articles of necessity, they were in many others articles of luxury and convenience, and when there came a time in which it was imperative for customers to exercise economy, the tendency was to dispense with them. The Company had suffered a great deal in this way, and many withdrawals had resulted from the stagnant state of business in Monte Video. On the other hand, owing to the improvements which the shareholders sanctioned some time ago, they had a considerable number of new shareholders to take the place of those who had withdrawn. Consequently they were, from a financial point of view, in about the same position as they were last year. They had deducted from the profits small sums for preliminary expenses and depreciation of furniture. This would be written off in a few years. They would propose a full dividend of 6 per cent. on the Preference shares, and to carry £1,000 to depreciation, and another £1,000 to reserve fund, because in the present state of things they deemed it prudent to have a substantial reserve. He continued to hope that when the wave of depression had passed, they would receive the full benefit of all the money they had spent out there. As stated in the report, they had spent a considerable amount in extending wires and cables to new subscribers; and under the head of profit and loss there was an increase in the subscriptions of £891. On the other hand, there was an advance in the expenditure of £1,130, owing to the extra taxes which they had been called upon to pay, and also on account of extra insurance. Expenses in London were a little higher, owing to the fact that in the previous twelve months they had received a little consideration from the Company for whom they had turned out of their old offices. Expenses in Monte Video amounted to 48 per cent. of their receipts. This showed a favourable comparison with the outlay of the Telephone Company on the other side of the river, whose expenses were 61 per cent. of their earnings. It showed that they must have had good management. He considered that the ordinary stocks of the Company would, before long, be a very valuable property. Had there been no withdrawals and the same influx of new subscribers, they could have paid their Ordinary shareholders 6 per cent. He concluded by moving the adoption of the report and accounts.

Mr. THOS. D. PETERS seconded the resolution, which was unanimously agreed to.

The CHAIRMAN them moved, and Mr. E. F. POWERS seconded, the declaration of the full dividend of 6 per cent. on the Preference shares of the Company.

The resolution was carried *nem. con.*

On the motion of the CHAIRMAN, seconded by Mr. POWERS, the retiring Director, Mr. Peters, was re-elected to his seat at the Board.

The auditors, Messrs. Gerard, Van de Linde and Son, were subsequently reappointed, and the proceedings terminated with a vote of thanks to the Chairman.

### Westminster Electric Supply Corporation (Limited).

The ordinary general meeting of the shareholders of this Corporation was held on Wednesday last at the offices, 4, Victoria Mansions, Westminster, under the presidency of the Right Hon. Lord Suffield, K.C.B.

The SECRETARY (Mr. Frank Iago) read the notice convening the meeting, and the report of the Directors was taken as read.

The CHAIRMAN said he had not much to add beyond what the shareholders already knew from the report. The maps hanging on the walls (as to which Prof. Kennedy would be happy to give any explanation that might be required) represented the work done up to last week. But since the maps were made up still further progress had been made, nearly 11¾ miles of mains now being laid. They all knew as well as he did the position of the Company, and the trouble and delay, partly necessary and partly otherwise, that had been caused in the progress of their operations not to speak of the difficulties that they had to deal with in obtaining stations and so on. But he must congratulate them, as he did himself, upon the great progress that had been made, considering the time that had been at their disposal in which to pursue their work. They had already a station at Millbank-street, Westminster, which, he was happy to say, was now in working order. And here he must give credit to their chief engineer for the great ability and energy which he had shown in carrying out the undertaking. Their other works were also progressing. They had already completed excavations at Davies-street, Mayfair, and some of the plant, two engines or more, he believed, and a considerable portion of the other necessary plant had been ordered, and was ready to be delivered. The works at Eccleston-place, Belgravia, were also proceeding apace. In fact, though they were not in a position to supply current to any great extent at present, he hoped that before long they would be able to do so. Any shareholders who might feel disposed to do so could go and see the Millbank-street station, and they would thus be able to form an opinion of the

kind and extent of the work that had been accomplished. He could assure them that the Directors had done everything they could to attend to the interests of the shareholders.

A SHAREHOLDER asked whether the applications for the electric light were very numerous.

The CHAIRMAN replied that they were, and were coming in every day. Of course the Company was not in a position to satisfy them as yet, and in many cases they had been obliged to say that they would not be able to supply current so early as was desired. He hoped that by the early part of January they would be able to supply nearly all the lights that were required. He believed he was within the mark in saying so.

A SHAREHOLDER wished to know whether an application had been made to the Stock Exchange for a settlement.

The CHAIRMAN replied that the application had been made and granted.

Mr. E. A. FRANKENSTEIN said he desired to ask three questions, which were of some importance. The first was when would the remainder of the capital be called up? The second was, what prospect of a dividend had they? And the third was, had they an absolute monopoly of electric lighting in the various districts mentioned in the Report?

The CHAIRMAN, in reply, said it would be impossible to say when the capital would be called up. As they all knew, their expenses were very great, and they would have to make another call shortly, payable early in the New Year; but when the whole of the uncalled capital would be applied for he was not in a position to state. With respect to the dividend, when they considered how much they had yet to do, he was afraid that they could not expect an early return. The third question was an important one. They had not an absolute monopoly. He understood from Mr. Wallace that they had a monopoly in a part of, but not throughout the whole of the district. He supposed that there would always be some rivalry on the part of other companies, and it would be their aim to attain such perfection in their arrangements as to give them a fair start of competitors. They were the only Company supplying in the district on their particular system, which they considered the best. They believed, also, that those to whom they supplied considered it the best. One very important feature in connection with it was the fact that in taking on new customers they had not to cut off the current from anyone else, as was the case with other companies—the London Company, for instance.

Mr. FRANKENSTEIN presumed, therefore, that so long as they remained best, the monopoly would be virtually assured.

The CHAIRMAN thought this to be practically the case. He might say that the only company in competition with them was the London Company.

Mr. S. R. SCOTT said he would like to say a few words from a shareholder's point of view. Having been long interested in this concern, and believing it to be an undertaking which would be eventually remunerative, he would say in answer to the shareholder opposite that they must give the Board some time to carry out an important work of this kind. With respect to the question of competition, he had always understood—perhaps they would correct him if he were wrong—that Parliament had given them, so to speak, half of their district to light, and that if they did their duty reasonably, the Board of Trade would maintain them in their position. Although they had a competitor, he was assured from the remarks that had been made that that competitor would not be a serious one, inasmuch as their system was likely to be more suitable and satisfactory in its working. He did not wish to mention names, but the impression which he had was that inasmuch as a company had to withdraw its light from some premises which this Company had already lighted seemed to point to that conclusion. He would like to say that, having had the opportunity through the kindness of Prof. Kennedy, of going over the works the previous day, he was quite astonished to find the progress which the Directors had made in providing for the lighting of that district. The station by the waterside, near the House of Commons, was in a very forward condition. In fact, practical working was going on when he was on the premises, so that within a day or two the station would be in full working order, and would render unnecessary the temporary iron shed which first of all contained the apparatus for supplying the Houses of Parliament. The other two stations had also progressed considerably, more especially the one at Eccleston-place, which would before Christmas make a great show. At the third station, and the last taken in hand, excavation was proceeding rapidly, and the workmen were putting in concrete at the present time, preparatory for the reception of the plant. Mr. Wallace reminded him of this fact, that when they got this station ready, they would not have to stand waiting for their machinery, which had been ordered, and was, in some cases, now ready. This was a matter which, in the first instance, appeared to some shareholders to be alarming because they thought that demands of this kind would be so great that they should have to wait for their plant. This was not so, however, for the plant was ready to put in position when the stations were ready to receive it. As to the dividend, he had heard that a neighbouring company doing business much on the same lines as their own, he believed (and he had heard this indirectly) was earning a very good dividend, and at its coming meeting it was going to show, though it had been at work only a few months longer than themselves, excellent profits, out of which they could distribute a good return. Another thing which he would like to say to his fellow shareholders was this. The Articles of Association of this Company were made at an early date — before the Company assumed its present proportions and its present capital. Under the head of "Directors" the Articles of Association said: "The remuneration of the Directors shall be £200 to the Chairman and £100 to each of the other Directors, and such other sum as shall be voted by the Company in general meeting." Now, he thought that seeing that the Directors had been working very hard, and, as they knew, most successfully, he did not think that that article in the Articles of Association mentioned an adequate sum for the payment of such a Board as they possessed. He would like to suggest to the Board on that occasion that they should at an early opportunity call a statutory meeting in order to alter the article he referred to. He understood that the Directors had taken no remuneration as yet, and he was sure that the shareholders did not want Directors, however good and however great they might be, to work for nothing. It would be absurd and unfair, and he, for one, having a large interest in the Company, was prepared to say that their Board ought to be properly paid. This came from him in his own private capacity as a shareholder. The Directors had not prompted him to say this. He said it as a shareholder, in the interests of other shareholders. He wished to see the work of the undertaking carried on as it had been hitherto, and in order to see this done, and to ensure the retention of those gentlemen on the Board they ought to be paid well. The present sum was not adequate for their service. He hoped that the article would be altered at an early date. With these remarks he would conclude by congratulating the shareholders on the position they now occupied. It appeared to him that the Company was going on rapidly to success. He spoke as a man of business, and not as an electrician. He kept his eyes open to what was going on, and he thought they were approaching success.

Mr. STEWART said he would be glad to hear whether the expenditure already made did or did not exceed, or was likely to exceed, to any great extent the estimates originally made. He wished also to ask the Board whether the capital was adequate to carry out the work.

Prof. KENNEDY said that the expenditure up to this time had been well within the estimates. The other question was not quite within his province.

Mr. STEWART thought it had been answered a good deal by what Prof. Kennedy had just said.

The CHAIRMAN thought that the capital at present was quite adequate to carry out the work. He did not know what might have to be done later on. In answer to a further question, he added that they were quite unable to judge what the sites would come to, but they considered that the prices had been reasonable. He thought there was every reason to anticipate a good dividend when they were fully at work.

Prof. KENNEDY, at the request of a shareholder, then gave an outline of the work done by the Company up to date by means of charts on the walls.

A SHAREHOLDER asked whether all the shares had been taken up.

The CHAIRMAN replied that all the shares issued had been taken up, and that there was a certain portion reserved.

Another SHAREHOLDER wished to know whether the remaining shares were ever offered to the public.

Mr. SCOTT said that he was adviser to the Company on the occasion alluded to, and he wished to say that 60,000 shares were offered, and over 40,000 were taken up by the public, and the Directors agreed to withdraw the balance. It was upon the strength of these 40,000 shares that the Company was now proceeding.

A SHAREHOLDER wished to know whether there was any danger attached to their system of electric lighting?

The CHAIRMAN said he could answer the question himself, but perhaps they would prefer to hear the Engineer on the subject.

Prof. KENNEDY explained that the system adopted by the Company was a low-tension one, and he thought he might say that it was entirely without danger. They had no high-tension current for good or evil, and no one could get seriously hurt by it, even under the most unfavourable circumstances.

The CHAIRMAN then formally proposed the adoption of the report.

Mr. E. BULNOIS, M.P., seconded the motion, which was agreed to *nem. con.*

The CHAIRMAN said that in closing the meeting he could not do otherwise than thank Mr. Scott for the kind remarks which the gentleman had made with regard to the Directors. As to the remuneration of the Directors he felt quite certain that his brother Directors would agree with him in leaving the question entirely in the hands of the shareholder.

Mr. SCOTT then proposed a vote of thanks to the Chairman and Directors, and wished to emphasise the fact, from personal observation of the progress of the undertaking, that they had as good a Directorate as could be found in the City of London. He desired to couple the vote with the name of Prof. Kennedy and the staff, all of whom had been equally energetic in carrying on the work.

The motion was seconded and cordially carried.

The CHAIRMAN having acknowledged the compliment, the proceedings terminated.

---

The following is the report of the Board of Directors referred to above :—The Board are pleased to be able to state that the affairs of the Corporation are proceeding in a rapid and satisfactory manner. The first work which claimed their attenntion after the allotment of the shares was that of obtaining suitable sites for central stations, three of which were required for the supply of the district which had been allotted to the Corporation. In January last the Board acquired the undertaking of the City of Westminster Electrical Syndicate, Limited, who had commenced business in the district, and thereby obtained possession of St. John's Wharf, Millbank-street, and also of the contract for electric lighting in the Houses of Parliament. After considerable trouble and delay, the Board succeeded in obtaining two other eligible sites, one in Eccleston-place, Belgravia, and the other in Davies-street, Mayfair, both being on the Duke of Westminster's estate. Pending the installation of the large central stations, current has been supplied from two temporary stations, one in the stoneyard adjacent to the Houses of Parliamenon and the other in Dacre-street, Victoria-street By means of these temporary stations the nucleus of a good business has been formed, and at the present time current is being supplied from

underground mains equivalent to about 6,000 eight candle-power lamps on circuit. The demand for current already far exceeds the amount which can be generated from the plant in actual work, but the new station at St. John's Wharf is now running, and able to take over the work in the Westminster district, and allow the Dacre street plant to supply as far as Belgrave-square, pending the completion of the Eccleston-place station. The installations in Mayfair and Belgravia are rapidly advancing. The mains have been laid in many of the principal streets, and are being laid as quickly as possible in the others, and the Board hope that current will be supplied from both these stations early in the new year. The Board have ordered plant—viz., engines, boilers, dynamos, batteries, &c.—to the amount of about 2,600 indicated horse-power for the three stations, a large part of which has already been delivered. This will be sufficient to supply about 40,000 eight candle-power lamps alight at one time, allowing an ample margin for steam power in reserve. According to present experience this will correspond to upwards of 100,000 eight candle-power lamps on circuit. The system of distribution adopted is the low-tension continuous current. The mains already laid are shown on maps, which can be seen at the Corporation's offices, and amount in all to nearly 11 miles, and permission has already been obtained from the authorities for the whole system of proposed mains. The financial year ends on December 31st, and the accounts will be made up and audited to that date, and the Board recommend that in future the annual general meeting of the shareholders should be held in the month of February, when the accounts would be ready for presentation.

## West India and Panama Telegraph Company (Limited).

The following is the report of the Directors for the half-year ended June 30 last, to be submitted to the twenty-seventh ordinary general meeting to be held at Winchester House, Old Broad-street, E.C., on Wednesday, next, the 12th inst., at 2 p.m.

The amount to credit of revenue is £52,351. 2s. 4d. (against £49,985. 11s. 9d. for the corresponding half-year of 1889), and the expenses have been £26,669. 17s. 4d. (against £24,458. 6s. 9d. for the same period in 1889), leaving a balance of £25,681. 5s. 0d., which, with the balance of £516. 19s. 8d., brought from the last account, makes a total of £26,198. 4s. 8d. Of this sum the Directors have placed £1,500 to reserve, leaving an available balance of £24,698. 4s. 8d., with which it is proposed to deal as follows:—

| | | | |
|---|---|---|---|
| First Preference Shares— | | | |
| Dividend, 6 months to June 30th, 6s. per share... | £10,368 | 18 | 0 |
| Second Preference Shares— | | | |
| On account of arrears of dividend to June 30th, £3 per share ...... | 14,007 | 0 | 0 |
| Balance to current half-year's account ...... | 322 | 6 | 8 |
| | £24,698 | 4 | 8 |

The traffic receipts for the six months show an increase of £2,779. 7s., as compared with the corresponding period.

Several interruptions to the cables occurred during the half-year, and the expenses for repairs amount to £13,936. 8s. 3d., being £2,900. 19s. 11d. more than those for the corresponding six months.

The shareholders will remember that at the time of the last general meeting negotiations were in progress with the Government of Barbadoes to lay a second cable to that colony in consideration of the continuance of the subsidy of £2,500 per annum for a period of 10 years. The necessary Act having been passed, the new cable was successfully laid between Barbadoes and St. Vincent in July last. In consequence of the laying of the new line above referred to out of the stock of cable in the West Indies, it has become necessary to replenish that stock for repairing purposes, and a contract has been entered into with Siemens Brothers and Company (Limited) for the manufacture of 215 knots of cable, which will be conveyed to the West Indies in the Company's steamship "Grappler," which arrived in the Thames on the 21st inst.

The Danish colonies of St. Thomas and St. Croix have renewed their subsidies for a further term of five years from December 31st last.

The Company was represented by the Chairman at the International Telegraph Conference recently held in Paris.

## Western and Brazilian Telegraph Company (Limited).

The following is the report of the Directors for the half-year ended June 30 last, to be presented at the twentieth ordinary general meeting of the Company, to be held at Winchester House, Old Broad-street, E.C., on Thursday next, the 13th inst., at 12 noon:—

The total earnings amount to £89,346. 13s. 9d., as against £86,555 17s. 10d., an increase of £3,290. 15s. 11d., compared with the half-year to June 30, 1889. The working expenses amount to £40,509. 13s. 3d., as against £39,104. 15s. 5d., an increase of £1,404. 17s. 10d. This increase is attributable to a larger sum having been written off the steamers on account of depreciation (£1,031), to the rise in the price of coals, to the opening of a new station, and to the larger volume of traffic. Including the amount brought forward from 1889 (£3,248. 16s. 6d.) and the dividend received upon the shares held in the "Platino" Company to June 30th, the balance to the credit of the revenue account is £59,970. 17s., from which has to be deducted £13,220 for Debenture interest, leaving £46,750. 17s., of which £7,500 has been placed to the renewal fund and £5,880 to the Debenture Redemption Fund. This leaves £33,370. 17s. The Directors recommend the payment of a dividend of 6s. per share, free of income tax, on the Ordinary shares for the half-year, being at the rate of £4 per cent. per annum, carrying forward £5,751. 7s. At the corresponding period last year the dividend was at the same rate. Since the last half-year's report 30 "Platino" shares have been exchanged for 18 shares of this Company. The dividend warrants will be posted on the 14th November.

An agreement for the absorption of the Montevidean and Brazilian Telegraph Company (Limited) will be submitted for the approval of the meeting. The undertakings are so closely allied that it is most desirable they should be brought under common control, and it is now proposed to purchase the above Company by an issue of 5,300 Ordinary shares of £15 each in the Western and Brazilian Telegraph Company (Limited), ranking for dividend earned after January 1st next. The agreement at present subsisting provides for the payment to that Company of a percentage of the gross receipts of the Western and Brazilian Telegraph Company (Limited). This payment, forming a portion of the amount paid to the London Platino-Brazilian Telegraph Company (Limited) is a charge coming between the A and B Debenture issue of the Western and Brazilian Telegraph Company (Limited). Consequent upon the arrangement now proposed, the proportion of this charge, hitherto paid to the Montevidean Company, will disappear.

The Directors have the pleasure to state that after long and difficult negotiation, the Government of Brazil have authorised the Company to lay alternative cables. The thanks of the Company are due to the Government of the United States of Brazil for this decision. Steps will be now taken to lay the lines immediately necessary.

## The Metropolitan Electric Supply Company, Limited.

The following is the report of the Directors, to be presented to the shareholders at the meeting to be held at Winchester House, Old Broad-street, E.C., to-day (Friday) at 12 noon:—

PATENT

SILICIUM BRONZE AND SILICIUM COPPER WIRE.

The best for overhead Telephone and Telegraph Lines,

AND ALL ELECTRICAL PURPOSES.

Hard Drawn High Conductivity Copper Wire.

ROLLED AND DRAWN PHOSPHOR BRONZE.

PHOSPHOR BRONZE — VULCAN — PHOSPHOR — DURO METAL

PHOSPHOR BRONZE BEARINGS, BUSHES, AND OTHER PARTS OF ELECTRICAL MACHINERY.

*SOLE PROPRIETORS of the British, Indian and Colonial Patents,*

THE PHOSPHOR BRONZE COMPANY (Limited),

*87, Sumner Street, Southwark, London, S.E.*

WIRE AND SHEET MILLS: BAGOT STREET, BIRMINGHAM.

Under the Electric Lighting Act it has been provided that the accounts of statutory supply companies shall be made up to the 31st December in each year, and that these accounts shall be presented to the Board of Trade not later than the 25th March in the year following. It will be remembered that last year the accounts were made up to the 30th September; in order, therefore, to comply with the above-mentioned statutory requirements, it is necessary to alter the period of the Company's financial year to the end of December, and the date of the annual general meeting to the beginning of next year. The accounts for the fifteen months ending the 31st December next will therefore be submitted to the meeting to be held early in 1891. The present meeting has been convened in accordance with Article 71 of the Company's Articles of Association, which provides that an ordinary meeting shall be held annually.

The Directors are pleased to have the opportunity of informing the shareholders that the Company is making steady and substantial progress in its works, and that what promises to be a large and remunerative business is being built up. During the fourteen months which have elapsed since the Company obtained Parliamentary powers, upwards of forty miles of electric light mains have been laid in pipes under the streets of the principal thoroughfares of the Company's districts. Current is being supplied from four central stations, two of which—viz., Whitehall and Sardinia-street—are fully equipped, while the other two—viz., Rathbone-place and Manchester-square—are on the eve of completion.

The Company's area of supply has been enlarged by the addition of the important and valuable district of Paddington. The Directors are giving careful consideration of the best means of supplying current in this district, and an advantageous site on which to erect a central station has already been acquired on favourable terms. While it is impossible, until the accounts have been made up and audited, to review the Company's financial position in detail, the Directors are of opinion that the prospects of the Company are such as to warrant them in looking forward to a satisfactory dividend being earned during the ensuing year.

In accordance with the Articles of Association, three of the Directors—viz., Sir James Anderson, Mr. J. Spencer Balfour, M.P., and Sir George Elliott, Bart, M.P., retire by rotation, and, being eligible, offer themselves for re-election. The auditors, Messrs. Deloitte, Dever, Griffiths, and Co. retire, and offer themselves for re-election.

## NEW COMPANIES REGISTERED.

**J. H. EVANS AND CO.**—Registered with a capital of £25,000 in £5 shares. Objects: To carry on the business of mechanical engineers, and machine and engineering tool makers.

**UNITED ALKALI COMPANY.**—Registered by H. Fonshaw and Hawkins, 5, Castle-street, Liverpool, with a capital of £6,000,000, in 300,000 Preference and 300,000 Ordinary shares of £10 each. Among the objects of the Company are the carrying on business as manufacturers of chemical products and drugs of all kinds, and as metallurgists in all its branches, and the carrying on of any business directly or indirectly connected with the generation, accumulation, distribution, supply, or application of electricity. Sir Charles Tennant, Bart., is to be the first honorary president.

## CITY NOTES, &c.

**BRAZILIAN SUBMARINE TELEGRAPH COMPANY.**—The receipts of this Company for the week ended October 31st amounted to £5,411.

**BRITISH INSULATED WIRE COMPANY (LIMITED).**—The Prospectus of this Company was issued on Friday last. The capital is £60,000, divided into 3,950 Cumulative £7 per Cent. Preference Shares; 3,450 Ordinary "A" Shares; 4,300 Ordinary "B" or Deferred Shares, and 300 Founders' Shares, all of £5 each. The present issue is for 3,450 Preference Shares, and 3,450 Ordinary "A" Shares. The Directors are Theodor Guillaume, (Messrs. Felten and Guillaume), 11, Billiter Street, London, E C., and Mulheim-on-the-Rhine, Germany; James B. Atherton, Mayfield, Huyton, Lancashire; W. Marriner Brigg, Hawkstone, Keighley, Yorkshire, and T. P. Hewitt, Eccleston Park, Prescot, Lancashire. The Consulting Engineer is Mr. R. E. Crompton. The Secretary *(pro tem.)* is Mr. E. England, and the Registered Office is situate at 15, Union Court, Castle Street, Liverpool. The Prospectus states that the Company has been formed for the purpose of acquiring, working and developing the British rights in the Patents now being worked in America by the Norwich Insulated Wire Company in the production of paper insulated telephone, telegraph, and electric light wires and cables of high insulation resistance, and low static capacity. The basis of the Patents is the recent discovery that pure vegetable paper possesses in a high degree all the qualities needed for an insulated material. The Norwich Insulated Wire Company's Works are capable of turning out, per month, 15,000 miles of insulated telephone and electric light wire, and the Company has large orders now on hand. The Company has secured the services of Mr. J. B. Atherton as General Manager. The Cables have been submitted to the examination of many leading electrical engineers both England, America, and the Continent, and in every instance with a highly satisfactory result. It is intended to proceed at once with the erection of a suitable factory on the land at Prescot already mentioned, with all the necessary machinery, for the manufacture, by means of the patents acquired, of cables, and all kinds of electrical conductors. The list of applications for shares opened on Friday last, and closed on Tuesday.

**CUBA SUBMARINE TELEGRAPH COMPANY.**—The estimated traffic receipts of this Company for the month of October were £3,200, as compared with £2,903 in the corresponding month of last year. The receipts for the month of July, estimated at £3,150, realised £3,134.

**DIRECT SPANISH TELEGRAPH COMPANY.**—The traffic receipts of this Company for the month of October show an increase of £154, as compared with the corresponding period last year.

**EASTERN TELEGRAPH COMPANY, LIMITED.**—The traffic receipts of this Company for the month of October, 1890, amounted to £59,589, as against £62,981 for the corresponding period of 1889, or a decrease of £3,392.

**EASTERN SOUTH AFRICAN TELEGRAPH COMPANY (LIMITED).**—On Monday, the 17th inst., at 2 o'clock p.m., at the Company's Offices, 50, Old Broad Street, E.C., 298 First Mortgage Debentures of £100 each will be drawn for payment on the 1st January 1891.

**EASTERN EXTENSION TELEGRAPH COMPANY.**—The receipts of this Company for October amounted to £47,117, as against £45,679 in the corresponding period, showing an increase of £1,438.

**GREAT NORTHERN TELEGRAPH COMPANY.**—The traffic returns of this Company are as follows:—Receipts in October, 1890, £26,000; 1st January to 31st October, 1890, £232,800; corresponding months, 1889, £229,200; corresponding months, 1888, £226,200.

**MIDDLESBOROUGH (U.S.A.) ELECTRIC LIGHT, HEAT, AND POWER COMPANY.**—Certificates for this Company are now ready, and will be exchanged for banker's receipts at the London office, Blomfield House, New Broad-street, London, E.C.

**MESSRS. RUSTON, PROCTER AND CO.**—This Company has declared an interim dividend of 5s. per share.

**STOCK EXCHANGE.**—Application has been made to the Committee to appoint a settling day for the shares of Elmore's French Patent Copper Depositing Company (Limited). The Committee have appointed special settling-days as under: Friday, Nov. 7th—International Okonite Company (Limited), Preference shares, Nos. 5,667 to 17,000, and Ordinary shares, Nos. 22,667 to 34,000 (also to be quoted in the Official List); Wednesday, November 12th—Dee Oil Company (Limited), shares, Nos. 1 to 13,400; and White's Asbestos (Limited), shares, Nos. 20,001 to 35,000. The Committee have ordered the undermentioned securities to be quoted in the Official List: Bell's Asbestos Company (Limited), 4,000 new shares, Nos. 20,001 to 24,000, and vendors' £6,000 Debentures, Nos. 249 to 308.

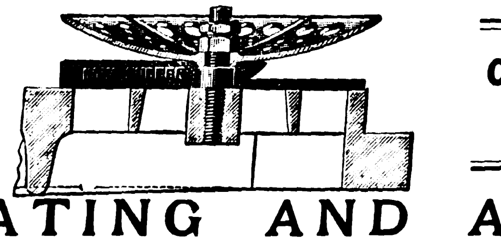
**WEST COAST OF AMERICA TELEGRAPH COMPANY.**—The traffic receipts of this Company for the month ending 31st October, 1890, amounted to £5,800.

**WESTERN AND BRAZILIAN TELEGRAPH COMPANY.**—At a meeting of the Board of this Company on Monday last it was decided that, after placing £7,500 to the renewal fund and £5,880 to the Debenture redemption fund, the Directors would recommend, at the forthcoming meeting, a dividend of 6s. per share (free of income-tax), being at the rate of £4 per cent. per annum, for the six months ended June 30 last. The traffic receipts of this Company for the week ending October 31, 1890, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company, Limited, were £4,235.

**WEST INDIA AND PANAMA TELEGRAPH COMPANY (LIMITED).**—The estimated traffic receipts for the half-month ended Oct. 31st were £2,910, against £2,735 in the corresponding period of 1889.

NEW VALVE

No Rubber, Percha, or Leather.



One-half the price of Rubber or Metal.

FOR CIRCULATING AND AIR PUMPS.

Unaffected by any Lubricating Oils. Does not Expand in diameter. Feed Water may be worked at any temperature Suitable for any shaped guards. Only one quality manufactured.

"12, John-street, Sunderland, 26th Sept. 1885.

"DEAR SIRS,—In reply to your letter of the 25th inst., the Valves I got from you have done their work well, and ARE AN UNQUALIFIED SUCCESS. I will continue to get them from you as required.—Yours faithfully, JAMES WESTOLL."

For further Testimony and Prices, apply to MOSSES & MITCHELL, 68-71, Chiswell Street, London.

# THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

## ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 652.—Vol. XXVI. FRIDAY, NOVEMBER 14, 1890. Price Fourpence.

## NOTES.

The Metropolitan Electric Supply Company, if we may judge from the figures placed before the shareholders on Friday last, has not let the grass grow under its feet during the first few months of its statutory existence. Since March last the Company has increased the number of lamps connected to its mains by 140 per cent., and its four generating centres, with their total capacity of nearly 7,000 horse-power, have now been got into working order. Supplying, as the Metropolitan Company does, an area of close upon five square miles, comprising some of the wealthiest districts of London, its Directors may well rest content with the development of the splendid territory already acquired, the more so since the station capacity still exceeds the present demand. It is satisfactory to learn that the "cost of coal and of working the machinery" has been found not to exceed 3½d. per unit; but it is the total cost per unit—that is to say, production plus distribution and management—upon which financial success will ultimately depend.

We wish every success to Mr. Crompton's scheme for the interchange of useful information, and hope that the first two forms, relating to efficiency at various loads and to the cost of producing and of distributing energy, will meet with less indifference than most of the circulars issued by the Chamber of Commerce. There are some matters which ever evade human inquiry. Where do dead donkeys and bent pins go? Is a tube boiler better than a shell? In reply to the first question, some thinkers suggest that they pass into the fourth dimension; but the second is as yet beyond our ken. We therefore wait for the replies to the circular.

The second form is excellent as far as it goes, but it may be feared that the request which follows it will be thought to have a somewhat personal colouring. Cables and other conductors covered with continuous insulation are to be charged with 5 per cent. for maintenance, but bare conductors, insulated by means of glass, porcelain, or other such imperishable materials, are to be debited with only 1 per cent. As we do not know, we will not prophecy about the relative cost of maintenance of the two systems of mains; but if Mr. Crompton will undertake to maintain the mains which he has laid for several different companies at 1 per cent., with say another tenth per cent. for net profit, we should congratulate the companies on their bargain. Fifteen per cent. on accumulators is a guaranteed figure, but although the old A. T. v. B. T. controversy resulted in a drawn battle as regards economy of generation and distribution, there is not any conceivable reason for supposing that a transformer need be charged with three times the depreciation that is set against engines and dynamos.

The operations of the Chemical Union, which has been registered under the title of the United Alkali Company (Limited), with a capital of six millions, has produced a further advance in bleaching powder, which has risen from £5 to over £6 per ton. This will give a better chance for the electrolytic methods of bleaching described in the article which is concluded in this issue, and may make the production of peroxide of hydrogen and of ozone of more commercial importance than hitherto.

Mr. Lane Fox has nearly lost the valuable services of Sir Richard Webster and Mr. J. F. Moulton, Q.C., by the smartness of his numerous opponents. These learned counsel have had a retainer from Mr. Lane Fox of ten years' standing, but the new Lane Fox Electrical Company was made a party to the case which is impending, and after examining precedents Sir Richard Webster found that the prior retainer was thereby invalidated. This case will therefore be dropped, and in a new case Mr. Lane Fox will be the sole plaintiff.

The only claim which the Lane Fox Company have hitherto attempted to enforce has been based on patent No. 3,988** of 1878, but since they consider that in certain quarters there is a disposition to evade rather than to fairly discuss terms, it is threatened that patent 4,626 of 1878 will be produced for the purpose of including all voltmeters as belonging to the category of "shunt electrometers." We understand from Mr. Lane Fox that no shunt instruments for measuring difference of potential had been suggested at that date, when the current for electric lighting was not "divided," and working at constant pressure was unknown. How many other patents Mr. Lane Fox has up his sleeve if his opponents do not play fair, we have no opportunity for estimating. Meanwhile, we congratulate him on being the inventor not only of parallel distribution but of the voltmeter.

We publish this week a Paper by Prof. Kimball on Electromagnetic Radiation, which briefly summarises the modern theory of electric action. Although very little will be found in it which has not already been stated, the simple manner in which

Digitized by Google

most of the new notions have been explained will form a welcome addition to the literature of the subject. Perhaps the most obvious tendency of recent electrical work is to bring out clearly the function of the wire conveying the current. The old notion was that the energy was in some way carried along the wire with the current, and the heating of the conductor was vaguely supposed to be due to frictional loss occurring in the passage. The view now held is, however, that the function of the wire is merely directive. The energy of the current exists in the air, or medium outside the wire, and is located in the magnetic whirls represented by the lines of force. Energy can only be transmitted when variations take place in these lines, and these variations are controlled by the current flowing in the surrounding wire. The manner in which the energy flows through the air has been studied more especially by Prof. POYNTING, whose views have, however, been subjected to a guarded criticism by Prof. HERTZ.

IT is an easy matter to see that the transmission of energy by electricity is strikingly different from the commoner methods. Whenever power is transmitted by ordinary means, material of great mechanical is necessary either as the active agent as in shafting, or as a means of constraint as in the steam engine, or as in transmission of power by compressed air. With electricity, however, two thin wires carrying 10 amperes at a pressure of a little over 2,000 volts will transmit 30 horse-power, although the carrying wires may be not only flexible but mechanically very weak. The strength of the leads has, indeed, no influence on the process. The energy flows through the air from the dynamo to the motor or lamps, and the current in the wires merely controls the flow which occurs. The actual mechanism involved in the process is as much a mystery as that causing gravitational attraction, though a general idea as to how a conductor can direct the flow of energy without being traversed by it, may be found on page 199 of Dr. OLIVER LODGE'S "Modern Views."

THE tests of the Willans engine and dynamo, which will be found in another column, significantly show how a dynamo excels a steam engine in commercial efficiency, not only on full load, but when giving a comparatively small output. Of the theoretical efficiency we need say nothing. There seems to be but little hope that any steam engine will ever give one-eighth of the energy which is contained in the coal, while it is a poor dynamo indeed that will not yield back seven-eighths of the energy imparted to its shaft. It is remarkable that the efficiency of a good dynamo remains high even at one-quarter load, and we have calculated the one-eighth, one-sixteenth, and one thirty-second loads for the purpose of drawing the curves. With a good indicator and careful observers the system employed is one which commends itself to engineers. Scientifically, a transmission dynamometer might give another decimal place; but that is quite unnecessary for the present purpose, and whatever may be the merits of such a method, they lose nearly all their weight when it is remembered that the dynamo in question was tested on its own bedplate and bearings, and coupled to and driven by its own engine.

The reduced price of glow lamps in the United States, which is referred to in our notes, raises several questions of interest, but the deductions which may be made in America are not of equal importance in this country. The practice of including lamp renewals in the charge for the supply of electric light has been seldom attempted with us, but it is a common custom in America. We are offered no guarantee of the duration of a lamp, nor, under the present monopoly, can we demand it. The vague tradition that a lamp should last for 1,000 hours is about as useful and reliable as that which recommends 1,000 amperes to the square inch as a maximum current density for wiring. Experience has shown that both traditions are safe. The one may be further investigated by simple arithmetic, in conjunction with the Board of Trade regulations and Mr. KENELLY'S researches, but the other can be confirmed only by the slow accumulation of records which are rarely kept, and which, when brought to light, too often refer to such phenomena as that which is described in our correspondence columns. A glow lamp will burn out as surely as a wax candle, but with the disadvantage that we can never tell how much longer it will last. Many other articles, however, an umbrella for example, have as uncertain a span of durability, but if we doubt the quality of one maker we can always try the productions of another. It is not improbable that the flood of cheap lamps, which may be expected when the spell of Cheesborough is broken, at the close of 1892, and that of Edison in November of the following year, will bring the question of durability *versus* cost into prominence.

**Poole.**—Consent has been given to the application made by the Brush Electrical Engineering Company for a Provisional Order.

**City and South London Railway.**—It is stated that the City and South London Railway will be opened to the public on the 26th inst.

**Lecture on Magnetism.**—Prof. J. A. Ewing delivered a lecture last week before the Dundee Naturalists' Society on his molecular theory of induced magnetism.

**Bromley.**—A formal resolution was passed at the last meeting of the Local Board empowering the clerk to take the necessary steps for obtaining a Provisional Order.

**Telegraph Line from Bombay to Calcutta.**—The new through telegraph line from Bombay to Calcutta, *viâ* the Bengal-Nagpore Railway, is expected to be opened on April 1st next.

**Appointment.**—The Secretary of State for India has appointed Mr. Arthur W. Thomson, C.E., B.Sc., of the Glasgow and West of Scotland Technical College, to be Professor of Mechanism and Applied Science in the College of Science, Poona.

**Electrical Trades Union.**—Members of the above union are specially requested to attend the fortnightly meeting on Saturday, November 15th, as business of great importance will be discussed, including Report of Delegate to London Trade Council.

**Trient.**—The Municipals central station at Trient is now in full work. This station possesses interest owing to the conductors being laid on the five-wire system, and also from the fact that the dynamos are on the same shafts as the turbines that drive them.

**The German Telegraph Department.** — The German Postmaster-General, Herr Stephan, issued last week a general order for facilitating the rapid despatch by telegraph of the Speech from the Throne, delivered on Wednesday at the opening of the Prussian Diet. The number of telegraph clerks at the chief office was doubled on that occasion.

Digitized by Google

**Commercial Cable Company.**—The Commercial Cable Company has opened a branch office at No. 4, Charing-cross, S.W. (opposite the Grand Hotel), and by means of this new office the West End of London is now in direct communication with the United States and Canada, &c.

**Anglo-American Telegraph Company.**—This Company has opened an office for the reception and delivery of telegrams at No. 2, Northumberland-avenue, Charing Cross, thus placing the West-end of London in direct telegraphic communication with New York, Canada, West Indies, &c.

**The Series System of Electric Traction.**—Early in April of the present year a large contract (100 cars) was obtained by the Short Electric Railway Company, at Rochester, N.Y. This Company has now made a successful start, though it is not mentioned whether the series method of working has been adhered to.

**Electricity and Gas in the United States.** — More than 300 gas companies are now operating electric lights in connection with their gas works, and supplying current to 32,000 arcs and 140,000 incandescents. In one year—from March, 1889, to 1890—the gas companies increased their ownership in electric lights to the extent of almost fifty per cent.

**Southend.**—The following resolution was carried unanimously at the last meeting of the Local Board:—"That the Local Board do forthwith make application to the Board of Trade for a Provisional Order authorising the board to supply electricity for public and private purposes within and throughout the whole or any part of the district of the Local Board."

**Electric Ploughing.**—An installation for the purpose of ploughing the land by electric motors has, says *Industries*, been set up in Spain on property belonging to the Marquis de la Laguna. The power of a water-wheel of some 20 horse-power will be employed, and the implement for working the land is expected to work at a distance of three miles from the generating dynamo.

**Woking.**—The Woking installation has been completed, and on Tuesday night the light was supplied for the first time to private consumers. The plant consists of two multitubular boilers of 100 horse-power each and two high-speed triple expansion engines, each driving a dynamo capable of supplying 2,000 eight candle-power incandescent lamps. The price charged is 8d. per unit.

**Proposed International Exhibition in Canada.**—A movement is on foot with a view to holding an International Exhibition in Canada during 1892, to celebrate the centenary of the opening of the first Canadian Parliament, the jubilee of the granting of responsible government to the colony, and the twenty-fifth anniversary of the establishment of the confederation of the Canadian provinces.

**Societe des Metaux.**—The official report made by M. Levasseur, liquidator of the Société des Métaux, shows that, notwithstanding the rise in copper, the liquidation will be of a disastrous character, the shareholders not receiving anything, and the holders of debentures and mortgages and other creditors only 34 per cent. of the amounts due to them. The final indebtedness is estimated at about 111,000,000fr., and the assets at 38,000,000fr.

**The Laying of the First Atlantic Cable.**—A drawing giving the longitudinal sections of the old "Agamemnon" and of the United States frigate "Niagara," the steamers engaged in laying the first (1858) Atlantic cable, has just been published by Mr. F. C. Webb, of 27, Forest-road, Dalston, N.E. The situations of the various cable-tanks in the two vessels are clearly shown, together with the length of cable in each. The drawing should be of great historic interest to submarine cable men.

**The Encouragement of Science.**—Mr. Frank McClean, of Rusthall House, Tunbridge Wells, has offered £12,000 to Cambridge University for the purpose of founding three Isaac Newton studentships for the encouragement of the study of astronomy and physical optics; one studentship to be filled annually, and to be tenable for three years. The offer is in reply to the Vice-Chancellor's invitation for outside assistance, contained in his address to the Senate on the first day of the October term.

**The French Post-Office.**—The French Chamber of Deputies has adopted a proposal brought forward by M. de Lannessan to the effect that each year one-twentieth of the receipts of the previous year but one of the Administration des Postes et Télégraphs should be devoted to the augmentation of the sums granted to that department, the money being applied to the improvement of the *personnel* and apparatus. Under this scheme the 1891 vote will be increased by one-twentieth of the 1889 receipts.

**Leamington.**—At a recent meeting of the Watch Committee of the Leamington Corporation, a letter was read from Messrs. Chamberlain and Hookham, contractors for the supply of electric light to the borough. Messrs. Chamberlain and Hookham demanded 5 per cent. on the unpaid account, and gave the Corporation six months' notice to terminate the contract. They disputed the accuracy of the surveyor's photometric tests, and added that they intended to apply for a Provisional Order to light the town. At a subsequent meeting of the Town Council the Watch Committee reported on this correspondence, which they advised should be left in the hands of the clerk. The report was adopted.

**The Civilian Electrician in Modern War.**—In a Paper recently read before the New York Electrical Society, Lieut. Bradley A. Fiske, of the United States Navy, takes for his text the fact that the regular naval and military forces of the United States would, in the event of war, be utterly unable to cope with all the electrical work that would be thrown upon them; and he proposes that a corps of military and naval electricians should be raised at each great electrical centre to assist the regular army and navy. The Americans have always encouraged and made great use of "irregular" corps, and doubtless Lieut. Fiske's idea will be speedily acted on, and the corps so formed should be able to afford much assistance to the authorities.

**Halle (Saxony).**—The horse tramway has been transformed into an electric tramway on the Sprague system by the Allgemeine Elektricitats Gesellschaft. The line, which is single, is four miles in length. Eventually twenty-five cars will be placed on the line, but at present only eight are in use. In the wide streets the conductor is carried on standards 18½ft. high, arranged close to the kerb, but in narrow thoroughfares it is supported on insulators attached to wires arranged transversely, the wires being fixed on insulators to the walls of the houses. Each car carries twenty-two passengers, and has two 15 horse-power motors. The line comprises several gradients, and the high maximum speed of 25 miles an hour is allowed.

**The Society of Arts.**—The first meeting of the one hundred and thirty-seventh session of this society will be held on Wednesday, November 19th, when the opening address will be delivered by the Attorney-General, Chairman of the Council. The following are some of the Papers which have been arranged for:—Ordinary meetings—December 10th, F. Bailey, "Electric Lighting Progress in London." Papers for which no dates have as yet been fixed:—"The Use of Petroleum in Prime Motors," by William Robinson; "Electricity in relation to the Human Body," by H. Newman Lawrence and Arthur Harries, M.D. Cantor Lectures—Gisbert Kapp, "The Electric Transmission of Power," February 16th, 23rd, and March 2nd.

**The Winston-Salem (N.C.) Electric Light and Power Station.**—An interesting instance of a combined power and light station is to be found at Winston-Salem (N.C.), where a local company has in operation an incandescent plant, consisting of four 400 light Edison dynamos; an arc light plant, consisting of two 50 light Brush arc machines; and a railway plant of two 50,000 watt Edison generators. The street railway has five miles of track, and there are seven passenger cars and four freight cars running. There are 38 tobacco factories and warehouses in the town, which ship 15,000,000lb. of tobacco every year. The roads have been very bad in this neighbourhood, and the grades very steep; hence the Company expect to do a profitable business in freight handling.

**Institution of Electrical Engineers.**—Among those who have accepted the invitation of the President and Council to the annual dinner of this Institution on the 20th inst. are the

Digitized by Google

Postmaster-General, the Attorney-General, the Presidents of the Royal Society, the Chemical Society, and the Institution of Mechanical Engineers, and the Vice-Presidents of the Institution of Civil Engineers, Sir Arthur Blackwood, the Astronomer-Royal, and Dr. Coleman Sellers, one of the members of the International Niagara Commission.—*President's Soirée:* We understand that in anticipation of the large numbers who are expected to respond to the invitation of the President and Mrs. Hopkinson on the evening of the 19th inst., the Prince's Hall has been engaged in addition to the Galleries of the Royal Institute of Painters in Water-colours.

**Copper.**—Subjoined are the Customs imports and exports of copper for the past ten months, and the figures for the same period of 1889:—

| | 1890. Tons. | 1889. Tons. |
|---|---|---|
| Copper in Pyrites | 1,097 | 1,115 |
| „ Ore | 1,606 | 1,624 |
| „ Regulus | 1,734 | 3,122 |
| „ Precipitate | 2,228 | 4,220 |
| | 6,665 | 10,081 |
| Foreign raw copper | 5,315 | 2,782 |
| Imports, October | 11,980 | 12,863 |
| Exports, October | 7,971 | 8,534 |
| Imports, January 1st to October 31st | 116,871 | 120,525 |
| Exports, January 1st to October 31st | 74,818 | 56,663 |

**Telegraphic Communication with Paraguay.**—The British Minister to the Argentine Republic and Paraguay states that since visiting the latter country in 1886 he notices a very considerable advance in the progress of the country in every way. Still, he adds, "that a want very largely felt at Asuncion is regular telegraphic communication with Monte Video or Buenos Ayres, and so with the world in general. At present (August, 1890), as in 1886, the telegraph line stops on the frontier of the Argentine province of Corrientes, the missing link between which and the line in Paraguay being furnished by a person of apparently somewhat lethargic habit, whose movements on the Parana in a canoe seem rather to depend on the rule of avoirdupois, as applied to the bundle of telegrams whereof he is bearer, than to the urgency or value of the messages themselves. Doubtless, however, an improvement will be apparent in this direction ere long.

**The Professorship of Mechanics at Cambridge.**—After a long discussion, it was decided yesterday to appoint J. A. Ewing, B.Sc., Professor of Engineering and Geometry at University College, Dundee, as the successor to Prof. Stuart. The appointment of Prof. Ewing, says an evening paper, is only a confirmation of the views which have been expressed by the Workshops Inquiry Syndicate in favour of developing the present material into a really good engineering school. It will be interesting to see whether it is followed by the foundation of an engineering laboratory, which has been declared to be the first necessity. It will be remembered that the plan by which the University bought over the shops from Prof. Stuart, and shared the management with him, had not worked satisfactorily, and it has been already decided that complete power is to be vested in the new Professor. Before, however, he is required to enter upon the details of management, the ground has been cleared by the decision to give up the secondary object previously attempted of doing work for profit, and everything is to be arranged in the interests of the students.

**The Introduction of Electric Power.**—The *Elektrotechnischer Anzeiger* is evidently no believer in the vision conjured up by Lord Salisbury in his speech at the first annual dinner of the Institution of Electrical Engineers in November last. "The event of the last century," said Lord Salisbury on that occasion, "was the discovery of the steam-engine. Now an agent has been discovered by which the force of the steam-engine, confined to its own centre, can be carried along far away from its original source. I do not despair that this distribution of force may scatter the present unhealthy aggregations of humanity. If it shall ever happen that distribution of power shall be so organised, you will then see men and women able to pursue in their own houses many industries which now require the aggregation of the factory." This idea, according to the journal in question, is quite wrong. Electricity is destined, it asserts, to annihilate small industries. A truce, therefore, to the songs praising electricity as the social panacea. Some such rôle may possibly be its destiny in a far-distant future; but meanwhile the introduction of electric power will only be the signal for a harsh industrial tyranny.

**Lower Prices for Incandescent Lamps.**—In commenting upon the present ruling prices of incandescent lamps in the States, 16 candle-power incandescent lamps now selling at 44 cents, against $1 in 1887, the *Electrical Engineer* of New York points out that this is due in a large measure to the reduced cost of obtaining a good vacuum. "There can be no question," says our contemporary, "that this considerable reduction in the price of incandescent lamps will lead to the manufacture and consumption of an increased number of lamps. It will, without doubt, also be followed by a notable change in the methods of operation of many central stations and perhaps private plants. With the cheaper lamp, it is evident that the life is not as important a factor in the cost of operation as formerly; so that lamps may be run at a higher candle-power and be more economical in the use of current than was desirable in the past. There is, therefore, every reason to believe that the lowering of the price of incandescent lamps will not only give us more of them, but will tend to brighten them, and this again will lead to greater demand for them."

**Electricity and Storms.**—The violent storms which occurred in France in August last, and about which considerable difference of opinion prevails amongst French meteorologists as to the part played by electricity, recalls, says *l'Electricité*, similar occurrences which happened some forty years ago, and which resulted in an interesting legal decision. The valleys of Mouville and Malaunay were visited by a terrific storm, and the spinning mills suffered severely. These were insured against fire and lightning, and the mill owners promptly applied to the insurance offices, who declined to pay on the ground that the damage had been done by the wind. The insurance offices urged in support of their statement a report recently presented to the Académie des Sciences by Pouillet, who asserted that electricity had but little to do with the storm. The mill-owners replied with a Paper read before the same body by Peltier, who attributed a similar storm at Cette to an electrical cause. The question was argued before the Tribunal de Commerce at Rouen, which nominated a committee of experts to investigate the matter. The case occupied the Court 10 days, and some 150 witnesses were examined. In the result the committee, which consisted of Gay-Lussac, Becquerel, Petit, and Lamé, solemnly affirmed that the storm in question was "eminently electrical," and judgment was given against the insurance offices accordingly. The case was carried to the Supreme Court with the same result.

**Porcelain Insulator Fittings for Mines.**—Mr. R. Oliver G. Drummond, electrical engineer to the De Beer's Consolidated Mines, of Kimberley, South Africa, has designed some fittings for use in mines. The switches and fuses are mounted on specially designed bases, insulated from the bolt that secures them to the timber or roof, and fitted with a cover to keep off the dust, &c., and to protect the workmen from shocks. The wires are drawn in from the lower side of the base, and consequently the water cannot run into the switch or the fuse. The lamps are suspended from a holder fitted inside a porcelain insulator, which is of such a shape that it becomes a reflector to the lamp, throwing the light downwards, and the heat of the lamp rising into this insulator keeps it warm and dry, no matter how full of moisture the air is. Any water dripping on to it from the roof runs off the outside of it, so that the lamps and holders are thoroughly insulated; and faults from bad insulation are impossible. When it is necessary to hang lamps in very wet places, the combination fitting is recommended, as the switch and cut-outs are arranged inside the reflector or porcelain insulator, and, as will be seen, the heat of the lamp is utilised to keep the insulation of these fittings good. This fitting has

Digitized by Google

many advantages in rock tunnels, or places where it is necessary to suspend the wires from the roof by insulators, and where there is no timber to which to attach the wires, lamps, cut-outs, or switches, and consequently holes have to be bored in the rock. These fittings are being supplied by the Electrical Engineering Corporation.

**Dynamo Telegraph Plants.**—The U.S. Postal Telegraph-Cable Company have recently had a very complete dynamo plant installed at their Boston office in Devonshire-street. The plant consists of eight dynamos and two motors of the Westinghouse direct current type. The total current capacity of the eight dynamos is 26 amperes, and they are so arranged as to provide for four different voltages, viz. : 40, 90, 130 and 375 volts. Seven machines are in constant use, while one is kept in reserve. The current from these dynamos is used to operate all of the Company's local, city, main, duplex and quadruplex circuits, including repeaters. Not a single cell has been left in the establishment. The number of cells replaced by this plant is 4,000. Power to drive the dynamos is furnished by the two Westinghouse direct current motors, which have a capacity of 10 horse-power each. The motors are supplied with current from the underground system of the Edison Company, connection being made with two of that company's Boston central stations so that any serious accident at either one of these would not result in a failure of the supply of current. One motor is sufficient to furnish all the necessary power. The current on the various circuits is regulated by 500 resistance coils. The Postal Telegraph Cable Company, says the *Electrical World*, is well established in Boston, having 20 branch offices in the most important business centres of the city, all in a flourishing condition. The system of the Company now reaches all but six States and Territories of the country and covers the larger part of Canada. About 1,500 offices and 90,000 miles of telegraph line are now in daily operation for the transaction of the Company's business.

**Electric Transmission of Power at Calais.**—For the past three months the Northern Railway Company of France has had in operation at Calais an electric light installation which possesses some peculiar features. At Calais three stations require lighting, namely, the town station, the harbour station, and the goods depôt. The generating plant is situated close to the town station, but is several kilometres distant from the harbour station and goods depôt. The plant consists of two 150 horse-power Chaligny engines, four 13 kilowatt (65 volts × 200 amperes) compound-wound dynamos, and four series wound dynamos, having a maximum output of 27 amperes and 1,200 volts (32·4 kilowatts). At the harbour station there are two series-wound motors, which drive two low-tension dynamos through shafting. At the goods depôt there is one series-wound motor, which drives two low-tension dynamos. The electric transmission of power is carried out on Brown of Oerlikon's principle; that is to say, a series-wound motor is driven by a series-wound generator at an almost constant speed, which is nearly, but not quite, equal to that of the generator. The electrical plant was constructed by the firm of Bréguet, and at each lighting centre a battery of accumulators is provided as a stand-bye, and to supply current during the hours of light load. The efficiency of this arrangement is, of course, considerably lower than would be the case if the lighting were carried out on the alternate-current tranformer system. The two motors at the harbour station, have at ¾ load, an efficiency of 55 per cent., and at full load an efficiency of about 60 per cent. Taking the commercial efficiency of the generators to be 85 per cent., the commercial efficiency of the whole arrangement at ¾ load is about 44 per cent.

**Electric Street Railways at Minneapolis and St. Paul.**—The St. Paul and Minneapolis electric street railway systems may be considered, says the *Western Electrician*, as one, as a car from any point in either city may reach any point in the other city by a continuous unbroken trip under a trolley wire. In the Minneapolis station the generating plant has a capacity of 3,000 horse-power. Oil is used as fuel. When complete there will be 15 150 kilowatt Edison compound dynamos. Two 15-horse power Sprague motors are used on each car. The novelty of this particular system lies in the fact that there is not a wire in sight except the overhead trolley wire. The feeders, mains, and track feeders are contained in a conduit underground. The conduit is located between the tracks, and is built as follows: Two-inch plank, first treated with fernoline, is used for constructing a long trough, a number of paper tubes, of the Interior Conduit Company's make, are laid in the box, and thoroughly joined together in continuous lengths. The tubes are raised a short distance from the bottom of the trough by cross-pieces. When the conduit has been completed bare copper wires are drawn in, and the trough filled with an insulating compound. The top of 2-inch pine is then nailed on. The upper surface of the trough is 8 inches below the paving stones. The manholes are 400 feet apart. A continuous unbroken main, except for fuses, is laid throughout the entire system. Numerous feeders join it at intervals, and equalise the pressure. Iron poles between the tracks are used entirely, and sub-feeders come out of the conduit from the main up through the hollow iron poles, and are connected to the trolley wires through fuse wires at every manhole. When the Minneapolis system is equipped it will include more than one hundred and forty miles of track, and two hundred electric cars will be in operation. There are now about forty cars in operation, and about one-fourth of the road has been completed. The St. Paul system will differ from that of Minneapolis in two very important features. A combination of underground lead cables and overhead construction will be used, and side poles will be employed instead of centre poles. The generating plant used in St. Paul will have a capacity of 7,000 horse-power. There will be ninety miles of track, and one hundred and forty electric cars in operation.

**Platinum.**—The market value of platinum is at the present moment nearly equal to that of gold, their respective prices being £4 and £4. 3s. Eighteen months ago platinum was to be had for about 30s. an ounce, and six months ago the price was under £3. Apart from the question of a possible "corner," and the ever increasing demand for platinum for electrical purposes, this 166 per cent. rise in price within eighteen months may be attributed in a large measure to the increased cost of production at the mines in the Ural mountains, whence we draw our chief supply of this metal. The owners of these mines, owing to their large yield of gold, were able to sell platinum comparatively cheaply; the gold, however, is now becoming scarce, and hence the platinum, which is still plentiful, can no longer be sold at so low a figure. Platinum, besides being used for the leading in wires of glow lamps, is largely used for electrodes in electro-chemical work, and up to the present no satisfactory substitute for it has been found so far as these applications are concerned. The history of platinum is as interesting as its characteristics are remarkable. During the sixteenth century it was observed that the gold ore from the Darien mines included grains of a whitish metal. This discovery was not made known by the Spanish Government, because they found that it furnished an excellent material for adulterating gold. It was only about the middle of the last century that the metal began to find its way into Europe. The Ural Mountain deposits were discovered about 1823, and they have been worked by the Russian Government since about 1828. Platinum is generally found in small grains, but masses of considerable size have been discovered, thus in 1822 a specimen, which weighed 11,641gr., from Condato, was placed in the Madrid museum Platinum was coined by Russia to the extent of half a million sterling between 1826 and 1864, when the coinage was discontinued. Almost all platinum contains iridium, which greatly increases its hardness and durability without impairing its power of resisting chemical agents. Liebig said that "without platinum crucibles, which share the infusibility of porcelain with the chemical inertness of gold ones, the composition of most metals could not have been ascertained, and chemistry could not have come to its present level." One of its most important uses is for large evaporating stills for the concentration of sulphuric acid. A still of this kind valued at nearly £4,000, exhibited at Vienna in 1873, was capable of concentrating 20,000lb. of sulphuric acid daily. This particular use for platinum has to a large extent been discontinued, and at one time the quantity of platinum thus set free caused a decline in its market value.

## AN IDEAL PHYSICAL LABORATORY FOR A COLLEGE.

BY PROF. OLIVER LODGE.

Sir W. Thomson has laid down the rule, and it is obviously an excellent one, that when one sets to work to design anything, be it a bit of apparatus or anything else, the right plan is first to contemplate ideal conditions and arrange the most perfect thing that can be devised, without regard to practical limitations and hindrances, and subsequently to modify the design so as to comply with these practical considerations.

Anyone designing a college laboratory is usually hampered by a multiplicity of local and other circumstances, of which scantiness of site and scarcity of coin are commonly chief. But in Utopia no such limitations exist, and hence in an ideal laboratory they are to be ignored.

What, then, are the requirements of a physical department, such as now exists at many of our chief Universities and Colleges? The following at least: a students' laboratory, a research laboratory, a lecture theatre, a workshop, and an apparatus store. To these, nowadays, it is becoming necessary to add an electrotechnical department. Private rooms for professors and demonstrators are also desirable.

The students' laboratory subdivides into senior and junior portions; the lecture theatre requires an annexe or preparation room; the apparatus store may develop into a museum on the one hand, and a common store-room on the other; the workshop requires power which is conveniently shared with the electrotechnical department; and a desk-room, or drawing office for diagram making, note writing, and book reference, is another desirable appendage.

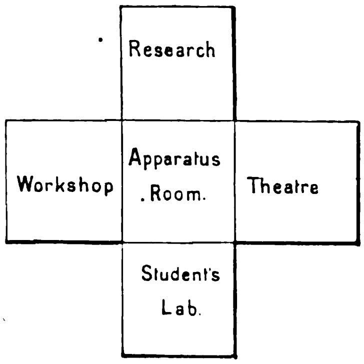

FIG 1.

South or north light at pleasure is useful in the research laboratory, and it will be as well to keep vibrating machinery as far from it and from the lecture theatre as convenient.

An underground basement for researches demanding constant temperature may also occasionally be useful. Absence of magnetic materials is a troublesome fad which can seldom be really carried out, and which it is simplest to ignore altogether. Nowhere, except in a terrestrial magnetic observatory, is it of any real consequence, nor is it feasible to consistently maintain it anywhere else under the stress of actual miscellaneous work.

A rock foundation away from rail and road traffic is an obvious desideratum. The securing of steadiness is a very real advantage, and makes many experiments easy which else would involve either special and troublesome devices or much night-work.

The carrying of apparatus up and down stairs is undesirable, and long staircases greatly add to the labour of supervision. Hence as much ground floor accommodation as possible is desirable; the rock not to be excavated by cellarage except in the one place where the uniform temperature basement is constructed. The rock should be levelled up and boarded over in such a way that when wished a semi-permanent masonry structure can be erected on it in any convenient place. Whether the joists that support the flooring could be bedded in indiarubber sockets, so as to prevent walking about jarring the rock, I don't yet know.

Side lights are best; low side lights for some, high side lights for most. The lighting should be thoroughly under control, but should always be potentially abundant, especially in dingy climates.

Furthermore, in the arrangement of the rooms, the principle made use of by Mr. Lewis Carroll in one of his numerical tales concerning the best position for the common eating-room of a definitely scattered family, is applicable also here, viz., that each room should be accessible to those others with which it has most immediate affinity by the smallest amount of walking.

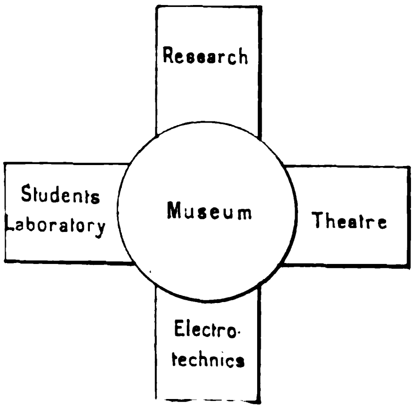

FIG. 2.

Applying these considerations, we get as the crudest possible design that shown in Fig. 1.

Below the apparatus room is, perhaps, the best place for the basement cavity. The workshop is unnecessarily large, and may include electrotechnics, especially as it may be two or more stories high. The students' laboratory will also be two stories, the upper one for junior students the lower for senior. It may be better to interchange the position of theatre and research laboratory if too much vibration is felt from machinery.

The theatre has no upper floor except a good experimental gallery, which is very useful. The apparatus-room must be lighted from above, and may have a gallery round it to permit free communication everywhere on the upper floor.

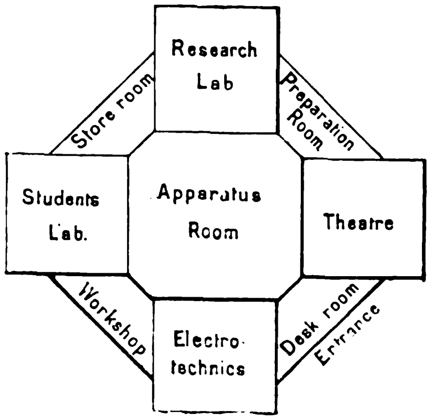

FIG. 3.

A lofty tower, open all the way down, with a spiral staircase like a shot-tower, is advantageous; and it may be a central feature, the base of it resting on columns and arches at the middle of the museum-room.

If some side light is desirable in the central room, it may be secured by such a modification as Fig. 2.

Minor details are not here entered into, such as the position of the preparation-room, the dark-room, store-room, and so on; but it is quite feasible in this last scheme to light the central chamber in a clere-story fashion, and to build four single-story chambers outside, one in each angle; especially since the lighting of the four wing rooms is in excess of requirements.

This brings us to the scheme of Fig. 3, and I incline to think that, in its broad features, this is a good design. Here the

Digitized by Google

store-room is readily accessible from the research department and from the ground floor (or senior students') laboratory. The preparation room is handy for the lecture assistant, who commonly (at least in my experience) assists the professor also in research. The workshop is near the power department, and is also near the students, over whom the mechanic in charge can exercise some supervision, and to whom he can give some assistance. The desk room is a quiet place, inoffensive to the theatre, and may also be, as regards diagrams, a kind of supplementary preparation room. If desirable to make the workshop less accessible to students, the two latter places may be interchanged. Absolute size is a matter of detail; but 40 feet square for each of the four wing blocks, and 60 feet across for the central octagon, strike me as suitable dimensions.

No details of internal arrangement, such as position of private rooms, and subdivision of the main blocks, are here entered into. So far, nothing but the relative positions of the blocks themselves is under consideration, and, before going further, I would ask the favour of criticisms; for the matter seems one of fairly general interest. In so far as it specially concerns me, it concerns me only as an affair of the future, not of the immediate present.

*(To be continued.)*

## ELECTRO-MAGNETIC RADIATION.[1]

BY PROF. A. L. KIMBALL, PH.D.

It is an interesting fact that the old notion that electricity is a substance, one of the so-called class of imponderables held by the earlier investigators of electrical phenomena, after being generally supposed to be dead and buried, should be resurrected and in a dress to suit the times should become a part of the orthodox scientific creed of to-day. Yet this is the case. The discovery that heat, instead of being a substance caloric, is the energy of motion of the particles of a body, together with the establishment of the principle of the conservation of energy, led to the idea that perhaps electricity was also in some way a form of energy. It is apparent, however, that this view is untenable, for there is this striking difference between the case of electricity and that of heat, in that a given amount of heat is always equivalent to the same amount of energy whether it is in a hot body or a cold body, whereas the amount of energy which a given quantity of electricity possesses depends entirely on its potential, or voltage.

But in saying that electricity is a substance it is not intended to convey the idea that like ordinary matter it has weight, and is subject to gravitation attraction, or that it excludes ordinary matter from the regions which it fills. It is rather to be conceived as a substance in the same sense as the luminiferous ether is a substance—that is, that it is an entity which is never transformed or changed into anything else, and so is indestructible, and its total amount unchanged. Whether it is subject to gravitation attraction and so has weight is entirely unknown.

The modern theory differs from the older ones, however, in this important respect: that whereas Franklin thought of each particle of the electrical fluid as acting at a distance, repelling every other particle, the modern theory supposes no such repulsive force, and all actions are explained by taking account of the strains in the medium surrounding the charged bodies; for the electric fluid, while pervading all bodies, is not equally free to flow in all. In some, according to this view, the particles of electricity are not free to move, but if forced aside spring back to their original position as soon as the straining force is removed, just as shot would if embedded in a mass of indiarubber. Such bodies are insulators. In others the particles of electricity can be moved from one place to another, just as shot can be moved about in a mass of tar or molasses; a certain amount of resistance is experienced, but when the force is removed there is no tendency for the particles to spring back to their original places. Such bodies are conductors; and one offering great resistance to the electric displacement is a poor conductor, while one offering but little resistance is a good conductor. It is the elastic force with which the displacement of the electricity in insulators is opposed which gives rise to the attractions and repulsions of electrified bodies in insulating media.

The discharge of an electrified body is due to the forcing of electricity out of the body by the pressure of the displaced electricity in the surrounding medium, and not to any inherent repulsion of one particle of electricity for another. Thus, in case of a Leyden jar the electrical strain in the glass between the two coatings, and to some extent in the air around it, is the cause of the discharge, since this strain cannot be relieved without forcing some electricity from one coating round to the other.

It appears, then, that the characteristic distinction between the older and modern theories of electricity is the recognition by the latter of the fundamental importance of the *dielectric* or insulating media. This great step forward was made by Faraday.

As soon as it is clearly perceived that electrical disturbances are communicated from one point to another by means of the intervening dielectric, the question at once arises: are these disturbances communicated instantly or are they propagated with a certain finite velocity? Within the past few years the experiments of Hertz have definitely answered this question, and there is now no doubt but that electric disturbances, like sound and light, advance with a certain definite velocity, which depends on the medium through which they are communicated.

### *Two Kinds of Electrical Energy.*

One way in which electrical energy may be stored up in the medium is illustrated in case of the charged Leyden jar, and the energy of the charge exists as a strain in the insulating medium, and is analogous to the energy of a coiled spring. There is another most important mode in which electrical energy can exist in the medium, and that is as the energy of a magnetic field. No energy has to be expended to keep up a magnetic field. A horse-shoe magnet may retain its magnetism for years, and is certainly not expending energy all the time; but to make a magnet requires a certain expenditure of energy which depends on the number of lines of force set up and on the strength of the magnetising current. While a current is flowing steadily around an electro-magnet it is expending energy, but that energy is merely being dissipated as heat in the conductor; there is no storing up of energy in the medium going on; but when we try to stop the current and make the magnet lose its magnetism, there is a sudden strong rush of electricity, greatly increasing the current. This is called the extra current, or current of self-induction; but it is simply the energy which was stored up as the energy of the magnetic field, which is thus suddenly returned to us as an increase of current. In the same way, on starting a current in an electro-magnet it may be some seconds, in case of a large magnet, before the current reaches its full strength. The reason is obvious; the energy supplied by the battery is being partly expended in setting up this magnetic field, and the current cannot reach its steady state until the magnetism is fully established.

It is believed that this energy exists in the medium in some way as energy of motion or rotation, the axis of the rotating particles being in the direction of the lines of force.

### *The Nature of an Electro-magnetic Wave.*

It has already been noticed that there is experimental proof that the inducing effect of an electric disturbance is propagated with a velocity which, as near as can be determined, is the same as the velocity of light. But it is important to go behind this fact to inquire in what way this disturbance exists in the medium, and what are the elements that determine its velocity. Let us first examine somewhat closely what takes place when a current is induced in a coil by the starting or stopping of a current in an adjoining coil. Let A and B (Fig. 1), represent two parallel coils of wire, and suppose a current is set up in A, then the lines of magnetic force will be somewhat as represented in the diagram, and the number of lines passing through the coil B, together with the resistance of the coil B, determines the amount of the induced current in B. This is the state of things as we ordinarily think of it, and

Digitized by Google

is true enough after the induced current has died out, and everything has come to a steady state; but when the current *begins* to flow in A the lines of force or magnetic whirls in the medium are first set up close around the coil A and spread outwards till they come to their final state, more and more being sent out from the coil till the field is fully established. Now the effect upon the coil B is produced in some way by the medium at the point where it is placed, as we have abandoned the idea of the coil A acting at a distance upon the coil B. The induced current is then set up in B by the action of the magnetic whirls in the medium cutting across the coil B as they spread out from the coil A. Of course, all these whirls that finally go through B must cut across that coil, and since each causes a certain amount of inducing action the total induced current must depend on the number of lines of force that finally thread through the coil B.

Now, an induced current always opposes the change in the magnetic field which brings it about. In the case under consideration the induced current is in such a direction as to oppose the cutting across the coil by the lines of force, and it is only when the induced current has died out, owing to the resistance of the coil B, that the lines of force come to their final state. But now suppose B is not a conductor at all, but an insulator, just like any other part of the surrounding medium, the inducing action due to the magnetic whirls cutting across B is just the same as if it were a conductor; the difference is that in case of the insulator the electricity cannot flow, but can merely be displaced a little, and springs back as soon as the displacing face is removed. This action must, therefore, go on in every part of the medium through which

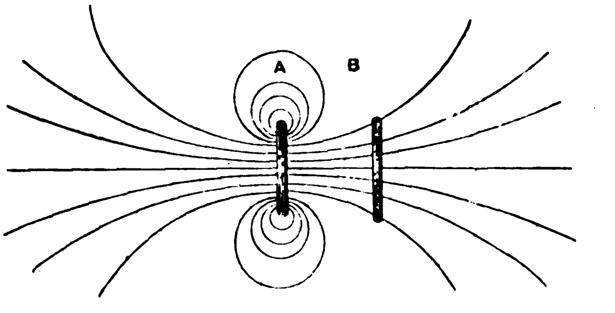

FIG. 1.

lines of force pass, or, in other words, in which magnetic whirls are set up. On starting the current, as the magnetic lines of force spread out in the medium, or as the magnetic rotation is communicated to more and more distant parts of the dielectric, at every point the starting of the magnetic rotation produces a displacement of the electricity, and this elastic resistance to displacement enables the motion to be communicated to more distant parts. The following analogy will make this clear: Let A, B, and C (Fig. 2) be three wheels geared together, and capable of rotating without friction. A and C are to represent two magnetic whirls, while B is a particle of electricity held in position by the springs on each side, which represent the elastic action of the insulating medium in urging the electricity back to its position when displaced. It requires energy to set up a magnetic field, as we have already seen. The energy is that of motion, and the analogy is to the energy of a rotating wheel. The wheels A and C, at least, must therefore be thought of as having a certain inertia, and when set in rotation their energy of motion represents the energy of the magnetic whirls.

Starting with the system at rest, suppose A to be set in rotation, it is easy to see that the inertia of C will cause the rotation of A to displace B to one side; if the rotation of A is in the direction of the arrow B will be displaced downwards; but the elastic force of the medium resists the displacement of B, and as the motion is gradually given up to C, B will move back and will come to its original position as soon as C is turning as rapidly as A. If the springs holding B in place were very stiff, so that a great force was required to displace B even slightly, the motion would be communicated rapidly from A to C, and if the springs were very weak the motion would be given up much more slowly. We may think of a long row of such gear wheels, every other one being held in place by springs, and it is plain that the length of time which it takes to communicate a disturbance from A to the last one will depend on the stiffness of the springs and the inertia of the wheels. The stiffer the springs are the greater will be the velocity of propagation of the disturbance, and the greater the inertia of the wheels the less will be that velocity.

*How the Velocity of the Wave Depends on the Properties of the Medium.*

The velocity of a wave is always determined by the properties of the medium in which it moves. Newton showed that in such a case as a sound wave the velocity is $v = \sqrt{\frac{e}{d}}$, where $e$ is the elasticity of the medium and $d$ is its density. In case of electro-magnetic waves an exactly similar expression holds, except that instead of ordinary elasticity we must put the elastic resistance which the medium offers to electric displacements, and instead of density we must put the effective *inertie* of the magnetic whirls.

Now the specific inductive capacity of a dielectric is a property which bears a direct relation to the resistance which the medium offers to electric displacement. This is readily seen that the capacity of a Leyden jar is proportional to the specific inductive capacity of the dielectric. But the capacity of a

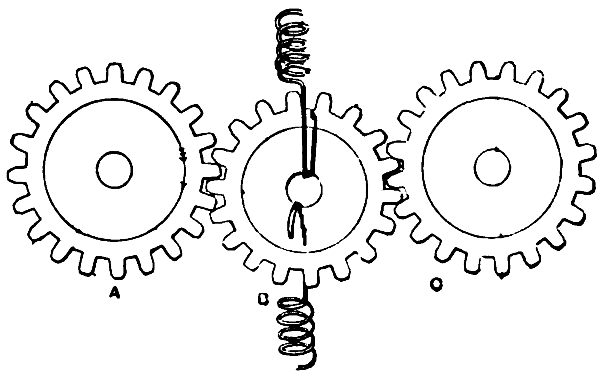

FIG. 2.

Leyden jar is evidently increased by *diminishing* the elastic resistance to displacement, for the less this resistance the greater the quantity of electricity than can be forced into a jar by a given difference in pressure or potential between the two coatings. It may be shown thus, that the specific inductive capacity of a medium is *inversely* proportional to its electrical elasticity, and therefore the greater the specific inductive capacity of the medium the less will be the velocity of the electromagnetic wave, other things being equal.

In a rotating wheel the energy of rotation is determined by the inertia of the wheel and the velocity of rotation. The inertia of the wheel belongs to it and cannot be changed, while the velocity of rotation may be made anything that is desired. In the same way, in determining the energy of a portion of a magnetic field, there is part that depends on the magnetising current and part depends only on the medium. It is this latter part, the *magnetic permeability* of the medium, as it is called, which corresponds to the inertia of the wheel; and it is this quantity which corresponds to density in the expression for the velocity of a wave given above. Thus the greater the magnetic permeability of the medium the less will be the velocity of the electric disturbance.

These two results are embodied in the following expression which was established by Maxwell:—

$$v = \frac{1}{\sqrt{K\mu}},$$

where $v$ is the velocity of the wave, K is the specific inductive capacity of the medium and $\mu$ is its magnetic permeability, all measured in the same system of units.

The value of this quantity has been carefully determined for

Digitized by Google

the case of vacuum where the insulating medium is the luminiferous ether, and is found to be the same as the velocity of light—186,330 miles per second, as nearly as experiment can determine. This is one of many remarkable facts connecting light and electricity.

*When are Electro-magnetic Waves Sent Out ?*

We have examined somewhat closely, in studying the nature of a wave of electrical disturbance, the wave sent out on starting a current, and evidently in a very short time the magnetic field, except at enormous distances from the current, comes to a steady state, and there is no longer anything like a wave. Of course, if we go far enough from the source of the disturbance the wave will be found there advancing with the velocity of light into the regions of space, but the magnetic effect of all disturbances such as we can produce must be vanishingly small, at a distance of a few thousand miles at most. If now the magnetising current is suddenly stopped, it is usual to think and speak of the magnetic field as being wholly done away, the magnetic whirls coming to rest and giving back their energy to the current, thus producing the extra current or current of self-induction. But this is not strictly true. Only a part of the energy that was expended in setting up the magnetic field is returned to the circuit in the self-induced current; the rest goes into space as a wave of electrical disturbance. The energy thus given off is sometimes said to be radiated, as a wave of energy is sent off from the electrical system just as the energy is radiated or sent off in waves from a hot body.

It is to be noticed, however, that there is no radiation or giving out of electrical waves from a steady current. The magnetic field around such a current remains constant, and energy is neither given up to it nor by it. It is only when changes occur in the magnetic field that the waves are set up. When a current is regularly reversed, as in the case of ordinary alternating currents, an electrical wave is sent out by each complete change, so that if the current is reversed 100 times a second, thus giving 50 complete alternations, there will be 50 waves a second sent out from the system, and since the velocity of propagation of the waves is 186,330 miles per second, the first will have gone that distance by the time the fiftieth is sent out: the waves will therefore each have a wave length of 3,726·6 miles. It is an interesting question whether the amount of energy thus given off is appreciable or not, for if a notable part of the energy of an alternating system is thus radiated by waves out into space it is an important point to be taken into consideration.

The amount of energy that is thus lost depends partly on the wave length and in part on the suddenness with which the current is started and stopped. The more abruptly a current is started and stopped the greater the amount of energy radiated. In all commercial cases of alternating currents, the amount of energy radiated must be inappreciably small, since the wave length of the disturbance is immensely great compared with the distance at which the magnetic field set up has any appreciable strength, and the reversal is not sudden, but very gradual, as the current rises to a positive maximum, and then, sinking to zero, passes to a negative maximum without any sudden or sharp changes in intensity.

When, however, the wave length is short compared with the distance to which the sensible magnetic field extends, a very considerable proportion of the energy expended in setting up the magnetic field will never be returned to the circuit, but will pass out into space in electro-magnetic waves. In order then that a series of energetic electro-magnetic waves may be set up, it is necessary to have an alternating current of considerable intensity, in which the reversals shall take place with such rapidity as to give rise to waves a few feet long.

*How to Obtain Short Electro-Magnetic Waves.*

When the electricity in a conductor is disturbed in any way it does not instantly come to rest, but surges to and fro, gradually coming to rest, just as when a tub of water is tilted the water oscillates from one side to the other, the motion dying out only gradually. The time it takes the water to surge backward and forward in a tub is perfectly definite, and depends on the shape and size of the vessel and the depth of the water. Just so in all conductors: when the electricity is disturbed it oscillates in a perfectly definite period, which depends on the shape and size of the conductor and the medium in which it is placed.

It will be found useful to compare the vibrations of the electricity on a conductor with the vibrations which a spring makes when set oscillating in a vessel of some viscous fluid, such as molasses. The spring rapidly comes to rest under these circumstances for two reasons—first, the resistance of the fluid causes some of the energy to be lost in heat; and secondly, part of the energy is sent out in waves in the fluid. As soon as all the original stock of energy is expended in this way the spring is at rest. So in a conductor the energy of the electrical oscillation is soon expended, partly in heating the conductor owing to its electrical resistance, and partly in electro-magnetic waves which are sent out into the surrounding medium.

In determining the time of vibration of a spring there are two elements that enter, its *stiffness* and its inertia. That is, the stiffness of the spring tends to make it vibrate quickly, while its mass and the mass of the liquid which it drags with it in oscillating tends to retard the vibration. In the same way, in an electric system, there are two elements which determine the period of vibration, its capacity, and its self-induction. Take the case of the discharge of a Leyden jar. When a jar is discharged the elastic force with which the charging is resisted is greater the *smaller* the capacity of the jar, so that a Leyden jar of small capacity may be compared with a stiff spring, and so the rapidity of the electrical vibration is increased by diminishing the capacity of the jar. In the discharge of the jar, as the electricity rushes from one coating to the other, it constitutes a *current*, and sets up a magnetic field around the conductor through which the discharge takes place; but it takes time to establish a magnetic field just as it takes time to set a heavy wheel rotating, and this constitute a *drag* on the electricity, so to speak, and the greater the number of lines of magnetic force thus set up the slower will be the rush of electricity, so that the greater the self-induction of the circuit in which the discharges take place (the coefficient of self-induction of a circuit being the number of lines of force which unit current will set up when flowing in the given circuit) the longer will be the time of oscillation of the discharge.

An exact mathematical discussion shows that the time of vibration of an electrical charge in a conductor when the resistance is so small that it may be neglected is

$$T = 2\pi\sqrt{CL}$$

where C is the capacity of the system and L its coefficient of self-induction.

*(To be continued.)*

**The Imitation of Solar Phenomena by Means of the Electric Discharge.**—In a recent communication to the Académie des Sciences M. Ch. V. Zenger states that observations of the effects produced by the Wimhurst machine on smoked glass plates led him to experiment with a view of obtaining an electrically produced imitation of various well-known solar phenomena. A large sheet of glass well dried on one face and covered with lamp-black on the other was placed between the terminals of a Wimshurst machine. The + pole was brought very close to the blackened surface, in the centre of which there was a circular tin disc. The − pole was from 10 to 20 cm. distant from the other side. Sparkless discharges disturbed the blackened surface, and a representation of the lines of electric force was drawn upon the glass. The result was a striking reproduction of a total eclipse of the sun, the metallic disc representing the moon. The lines of force produce around the edge of this disc all the chromospheric phenomena witnessed during a solar eclipse, such as eruptive, linguiform and auroral protuberances. If the experiment is carried out in a dark room red flames may be seen coming from the edge of the disc, which exactly resemble in form and colour those visible during a solar eclipse. Blackened glass balls submitted to the Wimshurst discharge exhibit white spots, the photographic negatives of which are precisely similar to those of sunspots.

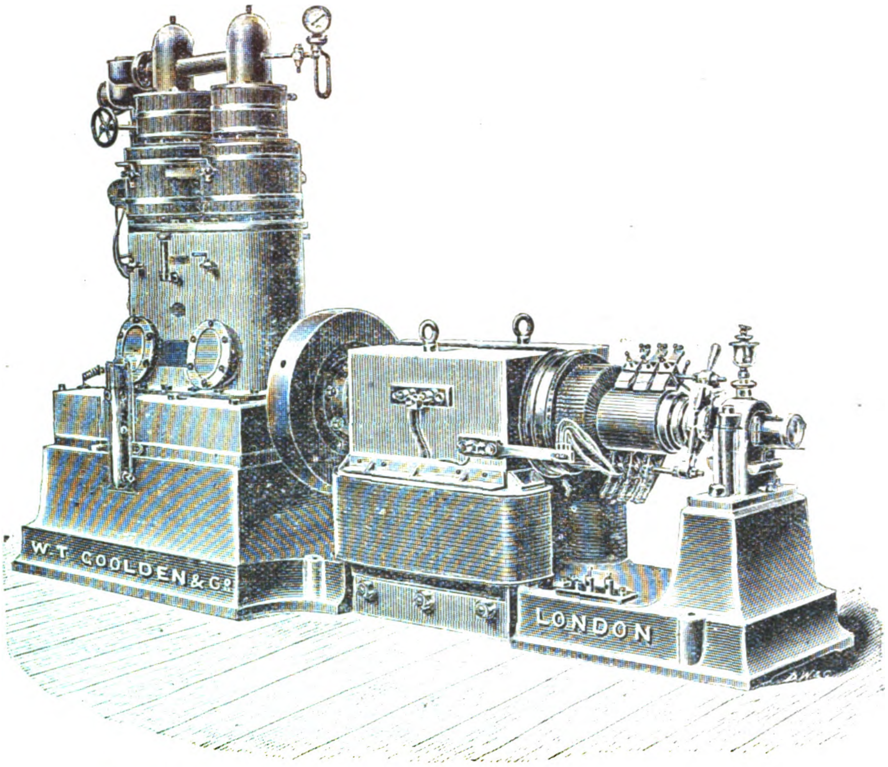
## TESTS OF A GOOLDEN-WILLANS COMBINATION.

Messrs. W. T. Goolden & Co. have recently made a series of tests of a 45-kilowatt dynamo, at their works in Woodfield Road, under exceptionally interesting circumstances. The Willans engine, which was destined to drive the machine, was delivered to the dynamo makers, instead of the more usual reversed custom, and, being ready for running, the tests were made during the building of the dynamo, thus enabling measurements of the various losses to be made as the different portions were put together. We are not aware that any such tests have been previously made, and, at all events, none have hitherto been published in such detail. The tests were made under several disadvantages; the engine and dynamo were quite new, and hence the mechanical efficiency, though high, is not as high as has been actually shown by later measurements, when the combination had been running a short time, and the journals had taken a *fair* bearing. The loss in the core was also probably augmented to no small extent, by the fact that this dynamo was originally designed for 105 volts, but the field excitation was raised to give 125 volts at the original speed, the induction being thus somewhat wastefully increased, and the leakage through the shaft and spider causing eddy currents and loss, being intensified.

The dynamo is one of a number which are being made for the station at St. John's Wharf, of the Westminster Electric Supply Corporation, whose stations were described in a recent issue. The arrangement of the dynamo differs from the well-known Willans combination bed plate, which is so largely adopted by the Admiralty, in the substitution of the well-known *overtype* pattern of dynamos for the *undertype*. Messrs. Goolden's reason for this is, that they consider that for dynamos up to, say 50 kilowatts, the greater accessibility of the brushes and ready removal of the armature, more than compensate for any advantage to be gained by keeping the shaft lower.

The dynamo itself has wrought-iron field-magnets, bored to receive the armature. The lower pole horn is of cast-iron, an arrangement suggested by Mr. Essen in his Paper to the Institution of Electrical Engineers last year, but previously in use by Messrs. Goolden and Co. The objection usually raised to overtype dynamos, that of the extra pull downwards, is met by an increased clearance being given on the lower side, so that the pressure on the outer bearing, which, when the dynamo is unexcited, amounts to 9 cwt., diminishes to 8½ cwt. when the magnets are excited. The outer end bearing is mounted in a spherical bed or seating, so as to automatically line itself in the event of the unequal wearing of the different bearings causing any twist to be thrown on the shaft.

The armature is a bar armature, the bars being laminated. The ends are Messrs. Goolden's "solid built," that is, they are composed of radial V-shaped strips, built up and insulated with mica after the manner of a commutator, thus presenting a completely solid end and preventing the ingress of dirt or wet. The field-magnet coils have internal ventilating space and outlets for the air. It will be noticed that all the electrical and mechanical sources of loss, except that in the armature coils, have been taken as constant at different loads. This is not theoretically correct, but the assumption is well within the limits of experimental error. The friction on the journals of the engine no doubt increases with a heavier pressure, but the principal friction is that of the pistons and valves, and this is constant. The friction of the shaft probably decreases slightly, and the eddy currents in the core are diminished, at heavy loads, by the demagnetising effects of the armature current. The dynamo was designed, and the tests were carried out by Mr. H. W. Ravenshaw.



Goolden-Willans Combination.—45 kilowatts at 440 revolutions per minute.

The electrical data are as follows:—Volts, 120; amperes, 375; watts, 45,000; speed, 440; armature resistance, ·013; resistance of field-magnet coils, 21·4 ohms.

INDICATOR TESTS OF GOOLDEN-WILLANS COMBINATION.

1. The engine was run with the armature disconnected, and found to absorb 8·43 indicated horse-power when running light at 430 revolutions.

2. The armature shaft and core were put in place, no windings being on, and running with the fields unexcited, 9·92 indicated horse-power was recorded; equivalent to 1·49 indicated horse-power for the shaft. (It is to be noted that this is excessive as the bearing at the time was running hot.)

3. The core only being in, the fields were excited, and 11·56 indicated horse-power recorded, the loss in the core being thus 1·64 indicated horse-power.

4. The armature was wound, and another test made, first unexcited, then excited, and deducting the value for the losses

*Commercial Efficiency of Dynamo and Steam Dynamo.*

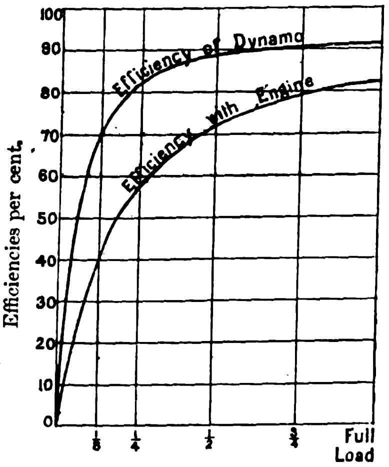
| 1 | 6,300 | 290 | 1,220 | 254 | 1,820 | 660 | 4,244 | 10,544 | 7·64 | 19·0 | 120 | 375 | 45,000 | 91·2 | 81 |
| $\frac{1}{2}$ | 6,300 | 290 | 1,220 | 254 | 520 | 660 | 2,944 | 9,244 | 8·85 | 27·8 | 120 | 200 | 24,000 | 89·1 | 72·2 |
| $\frac{1}{4}$ | 6,300 | 290 | 1,220 | 254 | 130 | 660 | 2,554 | 8,854 | 12·45 | 42·5 | 120 | 100 | 12,000 | 82·5 | 57·5 |
| $\frac{1}{8}$ | 6,300 | 290 | 1,220 | 254 | 32·5 | 660 | 2,456·5 | 8,756 | 16·60 | 59·4 | 120 | 50 | 6,000 | 71 | 40·6 |
| $\frac{1}{16}$ | 6,300 | 290 | 1,220 | 254 | 8 | 660 | 2,432 | 8,732 | 20·70 | 74·4 | 120 | 25 | 3,000 | 55·3 | 25·6 |
| 0 | 6,300 | 290 | 1,220 | 254 | 0 | 660 | 2,424 | 8,724 | ∞ | ∞ | 120 | 0 | 0 | 0 | 0 |

These calculations accord well with direct indicator tests. The dynamo giving 43,400 watts, the efficiency as indicated was 80·4 per cent.; and, when giving 26,500 watts, the efficiency was 72 per cent.

in engine, shaft, and the core, previously ascertained, the loss in Foucault currents in the bars was found to be ·34 indicated horse-power.

The experience and experiments of Messrs. Willans show that the frictional loss in the engine is nearly independent of the load. Hence from the above figures the efficiency of the steam dynamo can be given for any load, and the commercial efficiency of the dynamo calculated for any output.

The table above shows the results tabulated by Messrs. Goolden and Co., together with additions which we have made from calculations based upon the above data, it being noted that the loss in the shaft friction has been taken at ·39 indicated horse-power. (This value was found to represent an average in later tests, the above value being exceptional owing to the circumstance mentioned; but the individual test being for a difference, this was unimportant.)



Efficiency of Goolden Dynamo and of Willans-Goolden Combination.

Independent tests of these dynamos and engines, at the station supplying current to the Houses of Parliament, have been since made by Prof. A. Kennedy, consulting engineer to the Westminster Electric Corporation, giving even better results than the above, the commercial efficiency in some tests reaching as high as 85 per cent. and 86 per cent., but as further tests are being carried out on the same machines, the results are not yet complete.

**The English and American Patent Offices.**—The report of the Commissioner of the United States Patent Office for the year ending June 30th, 1890, has just been issued. In May last the Comptroller-General's report for 1889 was published. During 1889 21,008 patents were applied for in England, while in the year 1889-90, the number of applications in the United States was 40,201. The total receipts of the English Patent Office in 1889 from all sources were in round numbers £173,000, the expenditure being £79,286, so that there was a surplus of nearly £94,000. The figures for the United States are, total receipts, £250,000; expenditure, £216,000; surplus, £34,000.

## DRUM ARMATURE WINDING.

BY F. M. WEYMOUTH.

(*Continued from page 9.*)

*Introductory.*

Now, an accident that is liable to happen to a dynamo is what is known as a "short-circuit." The current from the machine under ordinary circumstances has open to it a course only through an outer circuit, of lamps and so forth, offering resistance to its progress. If by some mischance, however, such as a wire or piece of metal falling across the positive and negative terminals of the switchboard, connecting them electrically, a much easier way of getting from the one terminal to the other will be open to the current, instead of its having to go through all the circuit with the lamps; in other words, the resistance of the outer circuit will be practically eliminated. There will be a rush of current which the armature will not be able to withstand. The armature winding will heat; and may get red hot, and perhaps even melt. The insulation is destroyed, and metallic connections thereby set up which are fatal to the proper action of the machine. The result of a bad short-circuit is, therefore, that the armature is rendered useless, though often only one or two or a few of the sections are burnt, the remainder being uninjured.

Recalling our attention now once more to the wire-wrapped drum armature, from which we may seem to have wandered, it will at once be obvious that with the overlay of the wrapping at the hemispherical ends, to renew a few burnt sections, especially if these should be among the innermost, the whole must be unwound, involving expense and trouble. This is thus one of the principal drawbacks of this form of drum-winding, though not altogether peculiar to it. Another drawback lies in the fact that it is not possible with this form of end winding, and so much crossing of the wires, to prevent the close proximity of wires of high and low potential. Hence especial care is necessary as to insulation. Again, the combined heating of the wires at the ends where lying in such a mass, is not so easy to prevent, or to mitigate by ventilation, as when arranged differently. It has, however, its merits. Each section of the winding, of howsoever many turns, is whole throughout its length, without joints, which involve labour and expense to make, and form possible sources of resistance. It is in some respects easy of construction, dealing only with flexible wire. The fact also of its allowing of many turns per section as compared with most other windings, gives it a distinct advantage for obtaining high volts out of a small machine without the necessity of an inconveniently high speed—when a small current only is required. This point may indeed perhaps be considered as its most valuable feature.

We may now, however, proceed to the consideration of armatures wound not only for high volts but also for a heavy current. The chief difference between these and those we have discussed is that the conductors must be of a much larger section than that of mere wires, and will, in fact, become "bars" rather than wires. Before going on to describe

any particular heavy current winding, however, it may be advantageous, perhaps, first to consider some of the points that have to be borne in mind when getting out the design of such a winding. These naturally fall under the heads of efficiency and economy. The question of efficiency, however, in this connection, is mostly disposed of in the fundamental calculations of the machine. Granting, then, that the sections of all the conductors are of sufficient size to carry the intended current without undue heating, it is a matter of contrivance so to arrange these on the armature, that while the greatest economy in labour and material is aimed at, efficiency shall not be sacrificed. It thus becomes an object in designing an end winding, while retaining the necessary cross section, to aim, for economy's sake, at a minimum total length of copper. Compactness is also required, so that the winding may project the smallest amount possible beyond the ends of the core. As these parts of the winding generate no current, there is no object in their enlargement; while compactness assists not only economy in the copper itself, but also, by keeping down the total length of the armature, the total length of the machine as a whole is kept down, together with its weight, first cost, and floor-space, minimum floor-space being frequently a desideratum, especially on board ship. But while aiming at compactness, ventilation must not be forgotten, especially in the case of large machines, though there are makers who do not attach the importance to this point that others, probably the majority, attach to it. Again, it is well to have as few joints as possible in the coils, as these, depending on the human factor for their perfection, may be faulty, and so cause resistance, the extra labour and expense incurred in making them must, moreover, be remembered. An armature should not be too complicated, so that its construction may be comparatively easy and straightforward; and all joints should be accessible. Labour is thus economised; besides, by avoiding work that is at all "fidgetty," dependence on a few special men who may acquire the particular aptitude necessary, and whose services may be lost in a strike or otherwise, is avoided. With this last desideratum is in some degree involved another point of importance, which is, that parts burnt or otherwise damaged may either be removed and replaced with facility, or else that the whole winding should be capable of being easily dismounted and put together again for the same purpose. The conductors require to be well held on by steel wire wound round in bands outside, circumferential slipping being besides still further prevented by projections from the core and end plates. It may be borne in mind, indeed, with regard to this latter point, that by virtue of the work done in driving the armature, the parallel conductor bars are subjected to a magnetic drag tending to hold them back from revolving with the core and spindle; and this drag is no light matter; hence the necessity of fixing the coils well. To this magnetic drag is added the centrifugal force tending to make the coils fly off altogether.

There are, however, still some two or three other points that require attention. Of these, one is the question of a true balance. It is necessary to put on the winding and form up the ends with such symmetry that the centre of gravity of the whole armature when complete shall be in the axis of the spindle, and not outside. Now, in ordinary practice, the armature, when finished, is tested for balance by being rolled with its spindle at each end resting on two horizontal "knife-edges." If the centre of gravity of the whole be in the axis, it will rest in any position; but if not in the axis, the armature will then roll, oscillating backwards and forwards till it rests with the heavy side downwards, when extra weight must be soldered or otherwise be attached to the light side till a balance be attained. But it has to be noted that this is not really a true test. It is a question whether or not armatures are sometimes made having the centres of gravity of their two ends, taken separately, not in the axis, though equi-distant on opposite sides of it. A fault of this nature would not show on the knife-edges. But when revolving rapidly, there would be a tendency in an armature thus faulty for its axis to gyrate round the true axis of revolution in two cones, one at each end, having their apices united at a point within the true axis somewhere between the two misplaced centres of gravity. Hence a greater or less tendency to vibrate will still exist, though the armature might show a perfect balance on the knife-edges. This kind of error might perhaps be detected by mounting the armature within a magnetic field, on bearings supported on flexible standards, or, better still, on bearings slung from adjustable springs, and then with brushes lightly touching the commutators, revolve it as a motor. If the balance be true, with the centre of gravity of each end within the axis, the armature, when rotating at a tolerable speed, would evince a tendency to maintain a constant and steady axis in any one position, like a gyroscope. But if the balance be out of truth in the particular manner under discussion, a decided desire to "wobble" would show itself.

Another reason, however, for being careful as to symmetry, is to secure the perfect roundness of the exterior circumference of the completed winding, and its centre within the shaft axis. The clearance between the armature and pole-pieces may thus be kept to a minimum.

A remaining, and very important point, however, that arises, especially in connection with heavy current windings, is the liability of the conductor bars to heat by reason of "Foucault" or "eddy" currents generated within them individually, apart from the main current. In some kinds of dynamos other than those with drum or Gramme armatures, such, for instance, as those used for alternating currents, the coils, instead of being *revolved* in a field, are *translated* across a field edgeways. In other words, the coil is so placed that its plane is perpendicular to the lines of force of the field; being still kept in this plane, it is moved across the lines of force, and so cuts them. A current is thus set up in the coil. Now if, instead of a flat coil, a flat metal plate were used, and were made to cut through the field edgeways in a similar manner, a current would be caused to circulate in the plate in a plane perpendicular to the lines of force, this, indeed, being much the principle of Faraday's first disc dynamo. If the plate were turned so that its plane were parallel with the lines of magnetic induction, and then moved through them, no current, comparatively speaking, would be generated within it. This point is important. Now if, again, instead of the plate, a single metal bar be moved sideways across the field in a plane normal to the lines of induction, a current will arise within the bar; and this current will circulate within the bar in planes perpendicular to the lines of force, running along one of the sides parallel with these lines, and returning by the other. Thus it is obvious that as a current will produce heat, if the experiment with either the coil, the plate, or the bar, be carried out to any great extent, and they be moved rapidly and continuously through a sufficiently strong field, they may be made red hot; and the fact remains, that if a single insulated bar be laid along the periphery of an armature parallel with its axis of rotation, or held in a frame, and then revolved in an ordinary magnetic field, such as used for drum or Gramme dynamos, it will get hot from these internal currents alone. But in dealing with large "bars," however, there may also be borne in mind their capability of cooling as compared with wire, or bars of small section. It will be noted that whereas the transverse sectional area of a bar increases with the *square* of its diameter if *round*, or as the *square* of the side if of square section, the circumference, or outer surface, increases only in proportion to its diameter or thickness. Now capability of cooling, whether by radiation or convection, varies with the surface. Hence, a bar, say six times the thickness of a small bar or wire of round or square section, while it will have $6^2 = 36$ times the sectional area of the smaller, and so may carry about 36 times the current, has only six times the cooling surface. Hence large bars as compared with small ones, beside being heated by the main current and by eddy currents, are still further handicapped, so to speak, by their greater difficulty in cooling. The eddy currents in wires, it may be mentioned, are so trifling as to be negligible. In ordinary drum or Gramme-wound dynamos, where the field is bored concentric with the axis of the armature, these Foucault currents arise principally, if not entirely, when the bars pass under the trailing horns of the pole-pieces where the induction lines are particularly dense. By "trailing" horn is meant the last horn of a pole-piece which the bars leave or recede from as they revolve.

Digitized by Google

We may now proceed to consider the matter of mechanical construction, and see how all the various points we have enumerated are, and have been, dealt with in practice.

As we have just been touching on the subject of conductor bars, it will be convenient if we at once commence with these, and consider some of the ways in which this heating difficulty has been surmounted. The methods may be divided under two heads. Under the first, the difficulty is met by removing the principal cause of the evil; while under the second, the cause remains, but its effects are prevented from occurring by some counter-arrangement.

The plan adopted by Messrs. Mather and Platt comes under the first head. They avoid the difficulty by making the air space between the armature and the pole-pieces greater as it nears the horns either way, as shown in Fig. 3. Thus the principal cause of the heating is removed, inasmuch as the

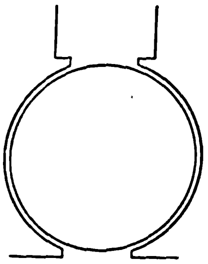


Fig. 3.

magnetic induction does not get so intense at the horns as it is wont to do when the air space is of even thickness. But it is under the second head that we may look for the most variety. The eddy currents may be prevented by so making or arranging the bars that a current *cannot* circulate within them. One method, instead of making the bar of one solid piece, is to compound it of several insulated wires or strips, in such manner that there shall be no internal circuit open to the current. Thus, Messrs. Siemens Brothers make their conductor bars of stranded copper wire cable, each wire separately insulated by varnish, and the whole brought into a rectangular section by hydraulic pressure, or by drawing through a die, or otherwise. As the Foucault currents will only circulate in an unbroken circuit lying in a plane normal to the lines of force, as already explained, it will be seen that no such circuit is open in the cable arrangement; conse-

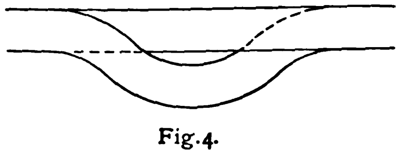

Fig. 4.

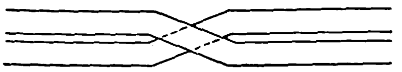

Fig. 5.

quently, the currents are not set up. Another method, somewhat similar, is to make the bar of insulated wires laid parallel, and soldered together at the ends so as to form a compound bar of rectangular section, to give the bar a half twist in the middle, and then to press or hammer the twisted portion in an iron mould so as to bring it to the same section as, and alignment with, the untwisted portions of the length. Yet another method is to make the bar of insulated copper strips or tape laid edgeways on the core in radial planes, and soldered together at the ends. The strips, thus laid, being in planes, for the most part approximately parallel to the lines of force they cut, will not, as we have already pointed out, be individually appreciably liable to eddy currents. But as they are in metallic connection at the ends, an internal circuit is open along the side strips and across both ends, which must to broken. Hence, this kind of bar also needs a half twist in the middle, and to be hammered in a mould, like the last. By means of the half twist, the current coursing along one side of the bar in each separate wire or strip is at the twist conducted to the other side, where it meets an opposing current, and so both are neutralised. It will, of course, be observed with regard to the strips, that if these be laid flat on the periphery of the drum, eddy currents could set up in each one separately.

A further method remaining to be mentioned, and still similar in principle, is one patented by Messrs. Crompton and Swinburne. This is illustrated, Figs. 4 to 7. The conductor bar here is simply made double; but at the middle of its length each half is so bent that it continues on the centre line of, and in alignment with, the other half. Figs. 4 and 5 show elevation and plan respectively, where one bar is bent to one side, and the other bent with a half-loop downwards, and also to one side, so that they thus cross each other. A groove is turned in the core to receive the half loops. Figs. 6 and 7 show an arrangement wherein the

Fig. 6.

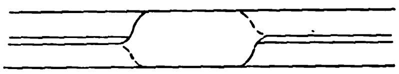

Fig. 7.

two bars are flattened merely, and so cross each other without the necessity of a groove in the core. Thus, the circulation of a current within the double bar is stopped by the tendencies in each half being opposed at the middle crossing, similarly as in those already described.

*(To be continued.)*

## MEETINGS OF SCIENTIFIC SOCIETIES, &c.

**FRIDAY, November 14th.**

Physical Society.

*5 p.m.* Papers to be read: "On Certain Relations existing among the Refraction Indices of some of the Chemical Elements," by Rev. T. Pelham Dale, M.A.; "Tables of Spherical Harmonics with examples of their practical use," by Prof. J. Perry, F.R.S.

**TUESDAY, November 18th.**

Institution of Civil Engineers.

*8 p.m.* Ordinary Meeting. Paper to be further discussed; "Steam on Common Roads," by John McLaren, A.M.I.C.E. Paper to be read, time permitting: "The Vibratory Movements of Locomotives," by Professor John Milne, F.R.S., and John McDonald.

Royal Victoria Hall.

*8.30 p.m.* Lecture: "Air and Water," by A. P. Laurie.

**WEDNESDAY, November 19th.**

Royal Meteorological Society.

*7 p.m.* Presidential Address: "The Relation of Ground Water to Disease," by Baldwin Latham, M.Inst.C.E.

Society of Arts.

*8 p.m.* Ordinary Meeting. Opening address of the Session, by Sir Richard Webster.

Royal Microscopical Society.

*8. p.m.* Papers to be read: "The Tube-building Habits of *Terebella littoralis*," by A. T. Watson; "Note on a New Marine Annelida," by Sarg. V. Gunson Thorpe. Adjourned Special General Meeting; Alteration of Bye-laws.

Institution of Electrical Engineers.

*9 p.m.* Conversazione at the Royal Institute of Painters in Water Colours.

**THURSDAY, November 20th.**

Institution of Electrical Engineers.

*7 p.m.* Annual Dinner at Criterion Restaurant.

Chemical Society.

*8 p.m.* Meeting.

**FRIDAY, November 21st.**

The Junior Engineering Society.

*8 p.m.* Presidential Address: "Electro-magnetic Mechanisms," by Prof. Silvanus Thompson, D.Sc.

Digitized by Google

# The Electrician.

**Published every Friday, Price Fourpence; Post Free, Fourpence Halfpenny.**
**Editorial, Publishing, and Printing Offices:**
**SALISBURY COURT, FLEET ST., LONDON, E.C.**
*Telephone No.* 2714. *Telegrams:* "ELECTRICIAN NEWSPAPER, LONDON."

*All Letters relating to Subscriptions, Advertisements and other business matters should be addressed to the Publisher, "*THE ELECTRICIAN,*" Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to "*THE ELECTRICIAN*" Printing and Publishing Company, Limited, and be crossed "Coutts and Co." All other letters to be addressed to the Editor.*

*All letters intended for insertion in "*THE ELECTRICIAN,*" or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever will be taken of anonymous communications.*

"THE ELECTRICIAN" *is published every Friday morning, in time for the morning mails. Subscribers should receive their copies by the first post on Friday morning.*

"THE ELECTRICIAN" *is on sale at the railway bookstalls throughout the Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices as above.*

*New Volumes of "*THE ELECTRICIAN*" commence in May and November.*

## SUBSCRIPTION RATES.

The rates for Subscriptions to "THE ELECTRICIAN" are as follows:—

| | 3 months. s. d. | 6 months. s. d. | 12 months. s. d. |
|---|---|---|---|
| For the United Kingdom | 5 0 | 10 0 | 19 6 |
| For Foreign Parts and Colonies:— | | | |
| Within Postal Union | 6 6 | 12 6 | 24 0 |
| Aden Borneo, Ceylon, China, India, Japan, Java, Labuan, Mozambique, New Caledonia, Persia, Philippine Islands, Siam, Transvaal, and Zanzibar | 7 6 | 14 6 | 28 0 |

## TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has by far the largest circulation of any English Electrical paper, and circulates all over the World.**

*Particulars relating to Advertisements will be promptly forwarded on application to the Offices as above.*

TRADE ADVERTISEMENTS *intended for the current issue must reach the Offices not later than First Post on Thursday morning. Renewals of expiring advertisement orders and alterations to standing advertisements should be in the Publisher's hands by Wednesday at latest. No alteration can be made in Wrapper advertisements after Wednesday evening.*

SMALL PREPAID ADVERTISEMENTS *(for Rates see page xv.) are accepted up to 4 p.m. on Thursday.*

## TECHNICAL PRINTING.

"THE ELECTRICIAN" PRINTING AND PUBLISHING COMPANY (LIMITED) *inform Electricians, Electric Light Engineers, &c., that they make a specialty of Technical Printing, and have a large Staff thoroughly acquainted with Electro-Technology. They can, therefore, promise Accuracy and Despatch in the Printing of Electro-Technical Literature, &c.*

## "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. (Royal 8vo.)

*Early in each year is issued "*THE ELECTRICIAN*" *ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. *The* DIRECTORY *was established in 1883, and the 1890 Edition consisted of about 850 pages of printed matter. The names and addresses of all persons engaged in the Electrical Industries at home and abroad may be relied upon as accurate. Useful Tables and Electrical Formulæ, and information specially compiled for this work are given, together with popularly-written Biographical Notices of the leading Electricians, Electrical Engineers, &c., accompanied in many cases by Portraits.*

*Orders for the 1890 issue should be forwarded* AT ONCE *to the Publishing Offices, Salisbury-court, Fleet-street, London, E.C.*

*The 1891 Edition is now preparing, and New Names, &c., can now be received.*

## ELECTRICAL BOOKS AND PUBLICATIONS.

*All Books, Newspapers, and other publications, dealing with Electrical and kindred subjects, can be ordered direct of "*THE ELECTRICIAN*" Printing and Publishing Company, who are proprietors of the well known "*ELECTRICIAN*" Series of Standard Electrical Works, and are agents for all the leading publishing houses at home and abroad.*

## THE SCIENTIFIC PAPERS OF JAMES CLERK MAXWELL.

Ten years ago the advance guard of physical science suffered a blow from which it has not yet recovered, a loss the full extent of which it may be impossible ever to estimate. The death of a veteran full of years and wisdom, though always a serious occurrence, is one that must occur now and again, and it is comparatively easy to acquiesce in it. But the death of CLERK MAXWELL at the age of forty-eight, on November 5th, 1879, came as an unexpected and withering blast to those students who were gathering inspiration from his writings, and hoping in time to be admitted to a stimulating and invigorating intimacy with the man himself. It deprived the younger generation of physicists of that which they felt almost a right to expect, the benefit of the nature wisdom, large experience, and kindly criticism, of one whose brilliant genius had already made itself lustrous. The man with all the potentialities latent in his brain has gone, and only the memory of a few privileged friends, a number of printed papers, and a couple of books remain. The books and the papers are fortunately immortal, and on their scientific value there is no need to dwell. Such a book as the Electricity and Magnetism marks an epoch: it is too early yet to estimate its influence. Sometimes it seems likely to take rank along with the Principia; while at the least it can be maintained that no book of equal importance and suggestiveness in physical science appeared between the two. The possible exception is Thomson and Tait; but it is too soon to institute comparisons, and there is really no antagonism between them; they cover a different field.

How MAXWELL'S work has proved the inspiration of Cambridge, and how splendidly the work which he began has been carried out and developed by his successors there is no need to tell. He was Professor at Aberdeen, in London, and at Cambridge (it was in London that he spun the B.A. unit coil), but it is with Cambridge that his name

Digitized by Google

will be associated, and it is a pity that he was ever tempted away into the less congenial atmosphere of Aberdeen. We waste our great men—they let themselves be wasted, not realising how great they are. No man as great as MAXWELL ught to be set to teach a set of young cubs such as a junior class is sure to be. Your steam hammer may be able to crack a walnut, but to see it cracking walnuts for its main work would be a pitiful spectacle. Three things MAXWELL did from which now we would have gladly freed him: he taught junior students the rudiments of physics, he superintended the erection of the Cavendish laboratory, and he edited the papers of CAVENDISH. The last he did well, but it was not work for him. CAVENDISH was a great man, but MAXWELL was a greater, and it were better to let some of CAVENDISH's fame rest in oblivion than to waste the last years, or any years, of MAXWELL's life over editing his unpublished papers. What a man does, he should publish himself, or take the consequences. The retentiveness and secrecy of CAVENDISH was a fault—a pardonable eccentricity it seemed, a wasteful error in reality; wasteful not only of his own, but of another's life. The greater the man, the worse the effect of this mania for secretiveness, for it takes another great man afterwards to understand and publish; and, moreover, the knowledge of the existence of a mass of unpublished material exerts a deterrent effect on the good work of younger men, and compels a self-criticism of their own work so severe as to be unhealthy. The best plan may be that adopted by those who boldly make up their minds to sacrifice any preposterous claim to infallibility, and publish as they go along.

Coming to the second act here suggested as in some sort wasteful, there may be a difference of opinion about it. Devising the Cavendish Laboratory is a good enough piece of work, but a smaller man might have done it equally well. Possibly better. It takes no heaven-sent genius to devise a laboratory. And as to the junior classes, whether in Scotland, in London, or in Cambridge, it is a barbarous and insular proceeding to use our leaders for such work, common as it is to this day in Great Britain. It is work from which the chief Continental philosophers are freed at a very early stage. The years of Maxwell's life most pleasant to contemplate scientifically are the early years, first with Forbes in Scotland, then as fellow and lecturer of Trinity, and his six later years of retirement at his country home in Glenlair (from 1865 to 1871), before accepting the Cambridge Chair. It was during these years that both the Electricity and the Heat were written.

The two large volumes which the Pitt Press has just issued under the editorship of Professor W. D. NIVEN, are a reprint of all his most serious contributions to the scientific literature of the day, together with a few memoirs and articles of a lighter cast judiciously introduced, such as biographical notices for *Nature* or elsewhere. A satisfactory and calmly judicious preface by the editor opens the first volume, which commences with an early note on ovals communicated through Professor FORBES to the Edinburgh Royal Society, when MAXWELL was a boy of 15. Then follow various optical and dynamical papers, with the early one on FARADAY's lines of force; and then come the tremendous memoirs on Saturn's rings, and on the dynamical theory of the electro-magnetic field. The second volume is largely occupied with papers on the kinetic theory of gases, on colour vision, and on dynamical chemistry. It contains, moreover, the selection of lighter memoirs and lectures which it has been deemed suitable to include. It is a pity that dates are not prefixed to the papers. Scientifically, the matter may be independent of date, but, considered from the point of view of the development of a human personality, dates add considerably to the interest. However, it is not our purpose now to formally review these volumes. We prefer to regard them as what they are intended to be, the memorial of one of the greatest geniuses of the age. They are but a fragment of what his life work might have been had he lived. He would have been only 59 now. Through all the recent development and apotheosis of his theories he might have lived, and we could have shared with him his keen interest and vivid appreciation, and have received from his own lips the most vividly telling presentment of it all.

But it is bootless now to speculate on what his influence might have been; and it is premature to discuss what his influence actually is. We are yet too near the source to be able to trace the course of the river of discovery which is flowing from this mighty peak. The words with which NIVEN concludes the more purely biographical portion of his preface, simple and studiously abstemious as they are, express a judgement in which everyone must concur:—"MAXWELL was thus cut off in the prime of his powers, and at a time when the departments of science which he had contributed so much to develop were being every day extended by fresh discoveries. His death was deplored as an irreparable loss to science and to the University, in which his amiable disposition was as universally esteemed as his genius was admired." . . . It does not appear "that the time has yet arrived when the quickening influence of MAXWELL's mind on modern scientific thought can be duly estimated."

## REVIEWS.

**Electric Light.** By JOHN W. URQUHART. Fourth Edition. (London: Crosby, Lockwood, 1891.)

This edition, which has been "carefully revised, with large additions," should have been carefully excised, with large subtractions. It aims at being a handbook, but its pages are seriously congested with obsolete matter. If a book be intended for a historical record, theories, definitions, and practical directions may be omitted; and, on the other hand, an elementary book, such as the one before us, should carefully distinguish between modern machinery and that which is old-fashioned. Typical specimens of the latter are useful in showing the germs from which the former have been developed, but their shortcomings should be pointed out. That the third edition was sold out in a few months shows that there is a want for such a book, but we hope that when the fifth makes its appearance a great deal of merely historical matter will be grouped by itself, or preferably omitted altogether.

**Practical Electrical Notes.** By PERREN MAYCOCK. Second Edition. (London: E. and F. N. Spon, 1890.)

Neither the title-page or the preface of this little book describe it as a pocket-book, and the contents are as unsuitable for a pocket-book as they could be. If it were bound in the ordinary fashion it would be a very fair little handbook on elementary electrical engineering. It is copiously illustrated with blocks from trade catalogues; a porcelain ceiling rose, for example, occupies a whole page. Joint-making is dismissed in one short paragraph, which describes a butt-joint as one which is made by bringing the ends of two wires close together and making fast by soldering, &c. The author does not inform us under what circumstances such a joint is generally used. The use of the words *decalescence, reluctancy, reluctivity, elastance, elastivity*, and *permittivity* might be well deferred until they are more generally adopted. Diagrams of no less than 34 methods of connecting electric bells are given, the subject being apparently more familiar to the author than dynamos, which are illustrated with equal profusion. We strongly recommend the slight alteration in binding, which will make it into a handy little book. The indexing should relate to pages, not to paragraphs.

## ELECTRICAL DISTRIBUTION BY TRANSFORMERS FROM CENTRAL AND ECCENTRIC STATIONS.*

BY DR. J. A. FLEMING, M.A.

*(Continued from page 15.)*

§ 20. **House-to-House Central Station at West Brompton.**— The House-to-House Electric Lighting Company have established at West Brompton, in London, a very complete Transformer station on the Lowrie-Hall system.

The site of the station is a plot of land 470ft. long by 60ft. wide, adjoining the Metropolitan District Railway. On this site has been erected a central station capable of supplying current to about 48,000 50-volt 10 candle-power incandescent lamps. The general appearance of a small portion of this station is shown in Fig. 55, and the whole station comprises dynamo and engine room, boiler house, testing-rooms, offices, stores, drawing and engineer's offices, water tank, coal stores, &c.

Then station when completed is intended to have 12 unit plants, each consisting of an engine, boiler, dynamo, and exciter, and capable of giving an electrical out-put of 100,000 volts. At the present time (1890) three such unit plants are actually in place, and the remainder will be added as required. The present supply is to about 16,000 eight candle-power 50-volt lamps, some 10,000 of which are at full load, burning at one time. The supply is to numerous private houses, flats, shops, St. Jude's Church, and other public buildings.

Each alternator is driven by a 200 horse-power horizontal coupled compound engine, by John Fowler and Co., of Leeds. The high-pressure cylinder is 15in. in diameter, the low-pressure 25in. in diameter; the stroke is 30in.; and the initial steam-pressure is 130lb. per square inch. The speed is 88 revolutions per minute. The cylinders are steam-jacketed. Between the high-pressure and low-pressure cylinder is suspended a massive flywheel, 14ft. in diameter, grooved for seven 1½in. ropes. The engines are governed by Hartnell's governor, which is driven from the shaft by cotton ropes, and controls the engine by acting direct on the expansion valves of the high and low-pressure cylinders, giving a range of cut-off in the high-pressure cylinder from 1 to 60 per cent. of the stroke, and governs the engine speed to within 2 per cent. The approximate weight of each engine is 24 tons. Each engine drives its associated dynamo and alternator by means of seven cotton ropes.

Efficient means for tightening the driving ropes are provided, consisting of two cast-iron rails of heavy section, fitted at one end of each with forcing screws; provided with holding-down bolts for the dynamo, the nuts of which are of rectangular form and sliding in grooves formed in the rails, the bolts being thus applied from above are removable without lifting the dynamo. The two rails are securely tied together with cast-iron distance pieces. Similar arrangements are supplied for the exciter. The foundations of all the engines and dynamos below ground are built of hard gault bricks, set in Portland cement, on a continuous slab of Portland concrete. The engine floor is raised three steps above the general floor line, and each engine base set up 14in. on a blue Staffordshire brick pedestal for conveniently reaching all the parts, and at the same time to secure natural drainage to the driving-wheel races. The floor on the raised platform is paved with blue Staffordshire bricks. All round the dynamos and exciters is a highly-insulated platform of crossed floor boards set on joists, with bitumen between the two sets of boards and linoleum laid through out. This platform is also raised 6in. above the general floor line

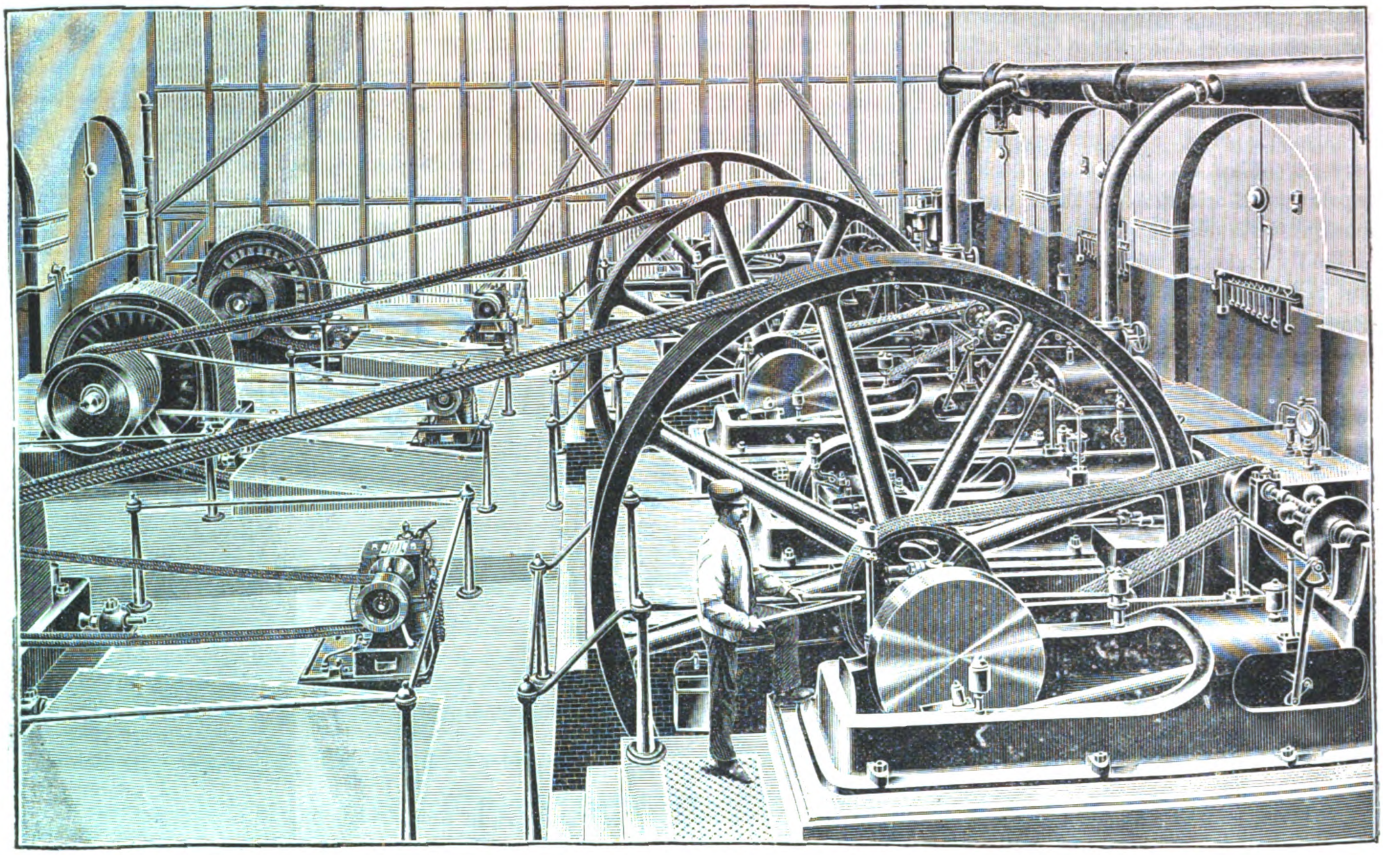

Fig. 55.—View of a part of the House-to-House Central Station, West Brompton. Main Engines and Alternators.

The boilers are the well-known Babcock and Wilcox water tube boilers with steam drum, capable of evaporating easily 5,500lb. of water per hour, and requiring not more than 1lb. best Welsh coal per 10½lb. water evaporated. Daily working pressure 150 (one hundred and fifty) lb. per square inch. The details of each boiler are as follows:—

| | Feet. | Inches. |
|---|---|---|
| Number of tubes in each boiler, 81 ......... | — | — |
| Length of tubes ................................ | 18 | — |
| Diameter of tubes ............................. | — | 4 |
| Length of steam drum ........................ | 23 | — |
| Diameter of steam drum ..................... | 4 | — |
| Length of mud drum .......................... | 5 | 6 |
| Diameter of mud drum ....................... | 1 | 6 |
| Number of sections or slabs in each boiler | 9 | — |
| Total length of boiler ......................... | 23 | — |
| ,, height | 14 | 8 |
| ,, breadth of all three boilers together | 22 | 9 |
| Heating surface on each boiler ............... | 1,790 | sq. ft. |
| Grate area in each boiler ...................... | 33½ | sq. ft. |

* All rights are reserved.

Digitized by Google

All joints in tubes, headers, hand-holes, &c., are metallic, no india-rubber, asbestos, or such like material being used. The entire boiler is suspended from a gallows or supporting frame, quite independent of the brick-work, thus allowing free expansion and contraction, and the removal, if necessary, of the brick-work, without disturbing the set of the boiler or connections. The steam drum, where exposed to radiation, is covered 2in. deep with non-conductor. The chimney shaft is common to all three boilers. Its dimensions are :—

| | Feet. | | Inches. | |
|---|---|---|---|---|
| Height from base-plate ......... | 100 | ... | 0 | above ground |
| Inside diameter ...................... | 5 | ... | 6 | |
| Outside diameter at base ...... | 11 | ... | 0 | |

These dimensions are sufficient for a battery of six boilers, the intention being to erect another shaft for the second six boilers. Below ground the chimney rests on a slab of concrete 20ft. square by 6ft. thick on the red London gravel.

The boilers are connected with copper connecting pipes to a 15-inch steel main pipe (this latter being of sufficient size to supply steam from 12 boilers to 12 sets of plant), carried on brackets fixed on the side of the wall, and each engine is again connected thereto by a copper bend pipe; the connections, both to engines and boilers, are arranged so that their spring or flexibility will allow for expansion of the main steam pipe, thus dispensing with any expansion joints. The condensed water from the pipe is collected in a receiver for use in the works and for the meters. The joints of this pipe are made with rings of copper tube covered with asbestos, fitting into a small spigot and faucet formed in the flanges. The exhaust pipe, 27-inch diameter, is also arranged to be common to all engines. It is of steel, similar to the steam pipe; the connection from the engines and to the heaters being of copper, arranged to take the expansion of the main pipe.

After passing through the heaters or the by-pass provided, the exhaust steam passes into the chimney, the drain from this pipe passes into a well, under the water level. The drain pipes from the engines are also all taken to a main drain pipe common to all engines and carried to this well and under water. This well is automatically drained of surplus water and prevents steam from being blown direct into the sewers.

The high pressure leads from the alternators are brought to a switch room, and all connections, governing, and changes are effected in this room. As at present (1890) arranged, each dynamo works on to a single and separate primary main. There are already about 25 miles of such primary main laid in the streets. The three pairs of leads from the three alternators and the ends of the three pairs of primary street mains are all brought to a switch-board, and by a simple 4 plug switch any dynamo can be put into any main. The leads from each dynamo have their own double-pole safety fuses, ammeter and voltmeter. There is also a double set of synchronising transformers for putting any pair of dynamos in parallel, as described in connection with the Leghorn Central Station. (See § 9.)

The mode in which this cross-connection of any dynamo to any main is made is very simple and practical.

Four straight terminals are mounted upon bosses of earthenware bolted to a slab of slate. The front earthenware bosses are deeper than the projection of the terminals from the face of the slate, to protect the terminals from dust, dirt, and the like, and to prevent accidental contact. The entrance orifices of these front bosses are funnel shaped, in order to guide the plugs to their respective seats in or upon the terminals. The back ends of the latter protrude through the back earthenware bosses, to which they are secured, and the terminals are formed to receive and bind the circuit conductors. This arrangement of four terminals upon their base is termed a terminal base. Upon a similar but smaller base of non-conducting material are also secured four plugs corresponding in position to the aforesaid terminals. In the centre a wooden or other insulated handle; a stop is fixed to limit the insertion of the plugs within the terminals. A strip of copper electrically connects each pair of plugs; and the base, with its handle and four plugs, is called a plug base. The combined four-terminal base and four-plug base is called a unit switch block.

The arrangement of the plugs, and that of their corresponding terminals, is that of a rectangle, nearly square in dimensions. This is to prevent the plug base being inserted wrongly in the terminal base, to make vertical connections (for example) instead of horizontal ones. The smoothing-iron form of the handle also serves to indicate the position in which the plug base should be held in switching, so that by the rectangular form and arrangement of the circuits it is impossible to plug the wrong terminals in a unit switch block. The terminals are made in the form of a split tube, to make spring contact upon the exterior surface of the solid plugs.

The requisite number of switch blocks are mounted upon a suitable support, in the form of a square. Upon one side of the square we connect each of the unit switch blocks to a generator, and upon a horizontal line with each of these a similar switch is placed, one for each, and connected to the working of the outer circuits.

In the respective circuits named are placed safety fuses, and the arrangement is such that one pole of a dynamo machine is connected to one terminal of a unit switch block, while the other pole is connected to the diagonally placed terminal of the same switch block. Similarly, each pole of the outer circuit switches is electrically connected to the remaining two terminals of the same block.

Provision is made by grooves at the back of each unit switch block to extend all the electrical connections to the adjoining unit blocks in the same symmetrical manner. For example, when four unit blocks are combined together as a square, with connections from two dynamos on one side, and connections to two

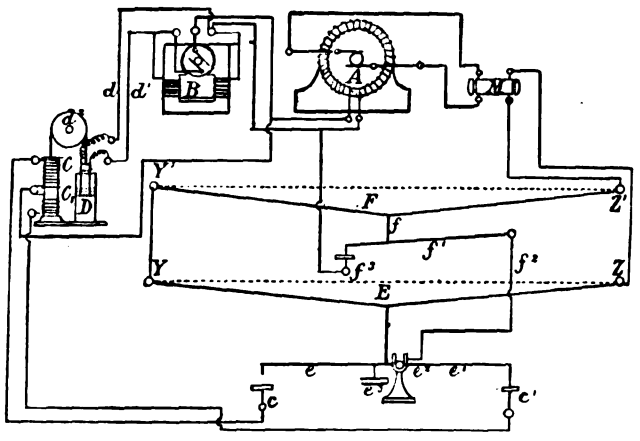

FIG. 56.—Diagram of Connections for Lowrie-Hall Pressure Regulator.

working circuits at right angles thereto, the whole of the current from the two generators can be conducted into one of the working circuits; or, the current from one machine led into one circuit, while the other machine is supplying the other circuit; or, one circuit is fed by both machines, while the other circuit draws its supply from one machine only; or, finally, both circuits may be fed by both generators, according to the number and arrangement of the plug bases engaged with their respective terminal bases. Thus, any number of generators and circuits can be electrically connected by adding the requisite number of unit switch blocks in the manner indicated.

The next important element in the system is the self-regulating arrangement, by means of which a constant electro-motive force of 2,000 volts is kept at the terminals of each dynamo. As the loss of volts in the primary mains between full load and lightest load is only $2\frac{1}{2}$ per cent., no adjustment is made for varying current in the main, but the terminal pressure difference is kept constant at the machine.

This is effected by regulating the exciter current by shunting more or less of the field current of the series-wound exciters.

From the terminals of one single coil of the armature of the dynamo is taken off a pair of wires, and the 75 volts of this coil is reduced by a small transformer to 50 volts. The current from the secondary of this small transformer is passed through two horizontal fine wires, like a Cardew voltmeter, and the greater or less expansion of these wires, as the E.M.F. of this coil of the armature varies, causes a greater or less sag of these wires. This expansion is then made to effect the regulation as follows:—

Across the terminals of the above-mentioned transformer, M, are the two fine wires, E and F (see Fig. 56), supported between

Digitized by Google

the fixed points, Z, Y, and $Z^1$, $Y^1$, whose normal positions when cold are shown by the dotted lines, the two wires being in series with one another, and connected by the wire, Y, $Y^1$. The field-magnets of the alternator, A, are excited by the exciter, B. Across the fields of this exciter a shunt of varying resistance is placed, connected by the wires, $d$, $d^1$; this shunt resistance is formed by two metal plates dipping in the solution in the electrolytic cell, D, and its resistance is altered by the raising and lowering of the plates into the solution, which is accomplished automatically by the passage of a current through either one of two solenoids or coils which pull up or down an iron core inside the coils; the top coil, C, lowers them, and the bottom coil, $C^1$, raises them, by the attraction of this movable iron core inside the coils.

This core is attached to the plates by a cord passing over a pulley $d^2$. To the centre of the wire E a cord is attached, the other end of which is fixed to the arm $e$ of the rocking arm $e$, $e^1$; this arm is pivoted at $e^2$ on a fixed support. If the electromotive force of the dynamo rises too high, the sag becomes greater, and the arm $e$ is pulled down by the weight $e^3$, and so makes contact on the table $c$; if, however, the electromotive force falls, the wire pulls the arm $e$ up, so causing the other arm $e^1$ to make contact with the table $c^1$. the resistance of the shunt, so that more current passes from the exciter round the fields of the dynamo A, whose electromotive force therefore rises. The arm $f^1$ is put in to cut out the action of the regulator in the event of the wire E breaking, for that wire by breaking would stop the passage of the current through the wire F, so making the latter contract and pull up the arm $f^1$, so breaking its connection with the table $f^3$. If no provision is made for this accident the arm $e$, by making permanent contact with the table $c$, would lower the electromotive force of the dynamo as far as the shunt would allow. In the shunt resistance, the two plates, which are fixed to an insulating piece, dip into the solution contained in the glass cell. The plates are supported by two chains, which pass over the two ebonite wheels; these chains make connection with the plates and terminate at two terminals, having sufficient slack to allow the wheels to turn their maximum distance either way. On a smaller pulley a chain is fixed, supporting the iron core, which moves up or down in the coils; the speed of the motion of the plates is increased or decreased by the ratio of the diameters of the pulleys. The coils are wound upon a brass tube, which is filled with glycerine to act as a dash-pot, the core acting as a plunger itself. The plates in the shunt resistance cell should be changed periodically to reverse the chemical action of the current

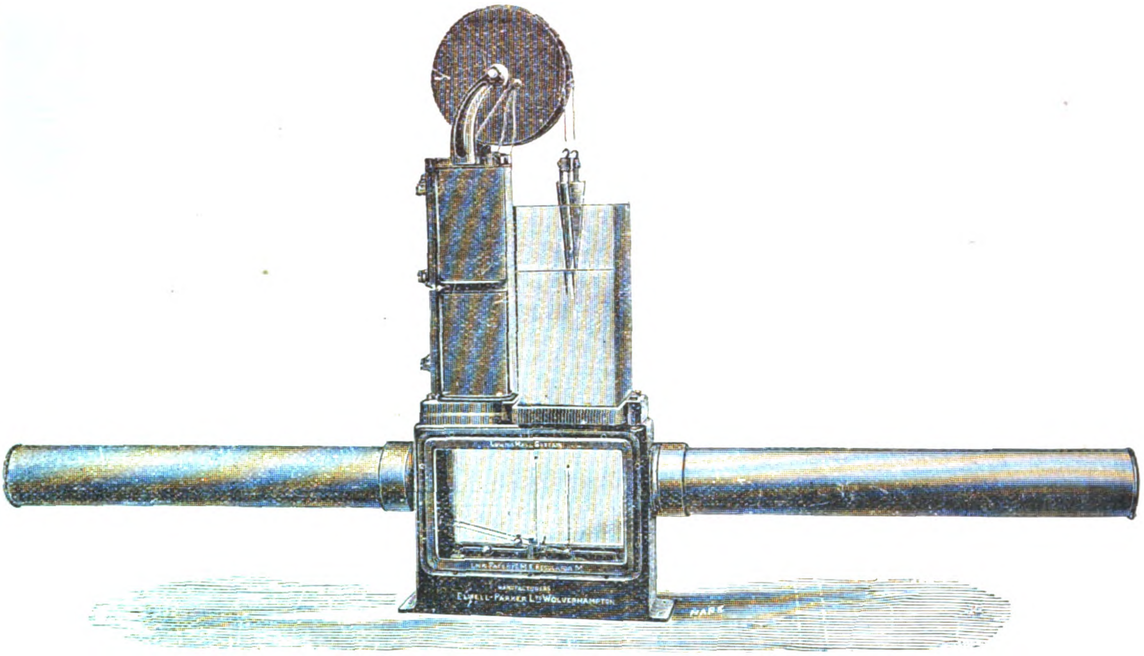

Fig. 57.—Lowrie-Hall Electromotive Force Regulator.

To the centre of the wire F the cord $f$ is attached, which raises or lowers the arm $f^1$, pivoted at its end, off or on to the table $f^3$. This table $f^3$ is connected to one pole of the exciter, and the pivot of the arm $f^1$ is connected by the wire $f^2$ to the pivot of the rocking arm $e^2$; the table $c$ is connected to the top coil C, and the table $c^1$ to the bottom coil $C^1$, the other ends of these two coils being jointly connected to the other pole of the exciter. If now the electromotive force of the dynamo rises too high, the arm $e$ falls, so making contact with the table $c$, the electromotive force of the exciter is therefore right across the coil C, one side being in metallic connection, and the other being connected through the table $f^3$, up the arm $f^1$, through the wire $f^2$, to arm $e$, so passing through the table $c$, connected with the coil C. This coil coming into action pulls the core up and so lowers the plates into the solution, which therefore lowers the resistance of the shunt, so causing less current to pass round the fields of the exciter and consequently weakening the field of the dynamo A, so lowering its electromotive force. These coils, C, $C_1$, it should be mentioned, are wound with fine wire and are of high resistance, so their connection across the exciter has no effect upon the dynamo A. If, however, the electromotive force is too low, the arm $e^1$ touches the table $c^1$, so shunting the current through the coil $C_1$, which, coming into action, raises the plates out of the solution, and consequently upon them. In the actual instrument thus designed to utilise the sag of a wire, the wires are stretched in a brass tube, in the centre of which is a containing box; at each end of the tube is a disc or insulation; on one of which are two movable brass strips to tighten the wires by the action of the thumbscrews. These are used to adjust the instrument; on each of these strips is a terminal, so that they make electrical connection to the wires. At the other end of the tube a brass piece is fixed, on to which both wires are screwed. The rocking arm is jewelled in both movements. The use of the guiding arm is to bring the centre pin on to the bridge, so that when the current ceases, the wire is free to contract. All the contacts are made of platinum, and the connections to the tables are made in the terminals underneath; these tables are all adjustable from below, so that their height may be altered, without allowing cold air to get into the tube whilst the current is on. The use of the other arm as a cut-out has already been described. The use of one wire is that of a cut-out as before described. It will be seen that another method of rendering the instrument still more sensitive or the reverse, is by moving the attachment of the cord on the rocking arm nearer to or farther from the pivot.

The external appearance of this regulator is shown in Fig. 57.

## THE ELECTROLYTIC PREPARATION OF BLEACHING AGENTS.*

BY A. RIGAUT.

*(Concluded from page 17.)*

But, after all, *the* important question is whether or not electro-chemically produced bleaching agents give results superior to chloride of lime? Here is a comparison between the cost of electric bleaching, mixed chlorides of magnesium and sodium being employed, and the ordinary chloride of lime process, the figures being taken from a recent pamphlet published by M. Hermite.

An "electrolyser" produces in 24 hours the equivalent of 100 kilogrammes of dry chloride of lime, 10 horse-power effective being required. The price of 100 kilogrammes of chloride of lime M. Hermite puts at 20 to 22fr., and the price is rising. For places where water power is available, we can have, according to M. Hermite, the equivalent of 100 kilogrammes of chloride of lime for 5·22fr. As the cost of labour is the same in the two cases, an economy of 80 per cent. is thus worked out. Where steam has to be employed we have—

| | Fr. |
|---|---|
| 10 horse-power for 24 hours (240 kilogrammes of coal, at 20fr. the ton) | 4·80 |
| 30 kilogrammes of sea salt, at 5fr. the 100 kilogrammes ... | 1·50 |
| 6 kilogrammes of magnesium chloride, at 12fr. the 100 kilogrammes | ·72 |
| Interest and depreciation (dynamo and electrolyser) | 3·0 |
| | 10·02 |

In this estimate, therefore, taking 1 horse-power hour as equal to 1 kilogramme (2¼lb.) of coal, at 20fr. (16s.) the ton, an economy of 50 per cent is effected. With less efficient steam plant and inferior coal the saving is still considerable. It is not surprising, therefore, to find that the electro-chemical method of preparing bleaching agents is being introduced into the bleaching industry. Employed, in the first instance, to bleach cottons and textile fabrics in the north of France[21], it has attained the most signal success in connection with the manufacture of paper.

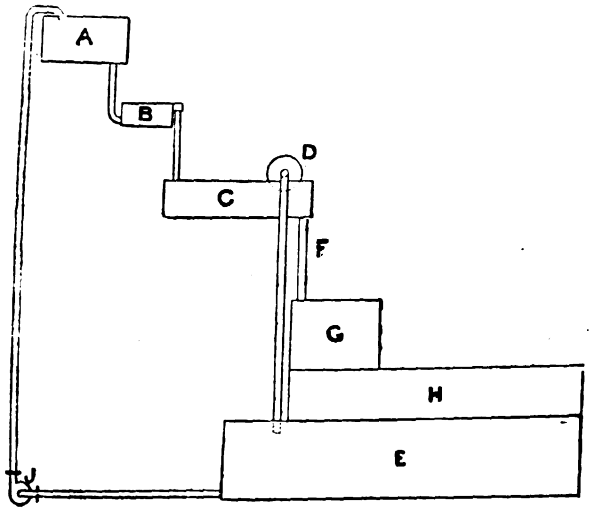

FIG. 3.

At the Centenary Exhibition a battery of "electrolysers" was at work in the Galérie des Machines. It was shown by M. M. Darblay, at whose works at Essonnes and Woergl no less than 15 "electrolysers" are actually employed. Other French firms employ the electro-chemical method, and in America, two years ago, 4·5 tons of pulp per day were treated by the Hermite process.

Figure 3 gives a general idea of an installation for electric bleaching as carried out in a paper factory. The liquid, containing a small quantity of free magnesia, passes from the vat A into a series of "electrolysers," B, and thence into the bleaching vessels C. The drum D takes the liquid off the pulp and sends it into the vessel E, where the centrifugal pump J returns it to A. Continual circulation is thus maintained, and the strength of the bleaching liquor is kept sensibly constant. When the pulp is well bleached it is sent down the tube F into the vessel G, whence it is passed through a press, which squeezes out most of the bleaching liquor, and this liquor falling into the vat E is also pumped back into A.

This electric bleaching of paper pulp is very suitable to the bleaching of difficult material such as jute, and it possesses the additional advantage that the fibres are not injured in the process. The increasing success of electric bleaching for this purpose has resulted in a whole series of patents in which electricity is specially applied to the paper industry, although the process is equally applicable to the purification of sewage, the purification of water, &c., &c. In 1886 Nation patented the application of electricity to the treatment of vegetable fibre for the production of paper pulp. He employed sea salt, but gave no details as to his apparatus. Stepanoff (1889) was engaged in investigating bleaching with sodium chloride, being of opinion that magnesium chloride was too dear in Russia. Stepanoff makes use of platinum and lead electrodes, and employs a current of 40 amperes at 45 volts. His plant can turn out 300 litres (66 gallons) of bleaching chloride per hour, that is to say, 72 hectolitres (1,584 gallons) per day of 24 hours; an amount equivalent to 37·5 kg. (82·5lb.) of chloride of lime. The quantity of platinum employed in the "electrolyser" is one-third of that employed in the Hermite apparatus.[22]

Kellner in Austria prepares a bleaching solution by the electrolysis of sea salt. In one of the processes which he has described, the saline solution has added to it an alkali (soda, lime, or magnesia) to prevent the escape of the free chlorine. The "electrolyser" is especially intended for the bleaching of paper pulp. The pulp impregnated with sodium chloride passes between two revolving electrodes which are in the shape of rollers, and placed face to face. The electrolysis of the salt is thus carried out in the pulp itself, which is bleached by the reactions produced. The roller forming the anode is of carbon. In the case of some fibres it is an advantage to pass the pulp *successively* over the cathode and anode. This result is arrived at by arranging a layer of felt between the two rollers so as to divide the pulp into two halves, one of which is in contact with the anode, and is impregnated with anions, chlorine, oxygen, &c., while the other half passes over the cathode, is charged with cathions, soda, and hydrogen. On the cathode, therefore, the fibre is washed and disintegrated, while at the anode there is a bleaching action due to the chlorine and oxgen. Another method of Kellner's consists in modifying the properties of the materials used in the manufacture of paper by the aid of the electric current. The texture of a paper depends on the nature of the fibre employed in its manufacture. Thus, paper made from flax differs considerably from that made from cotton. Kellner asserts that he is able at will to give paper the texture of flax paper or cotton paper. Weak alkaline solutions can, in the presence of the electric current, transform flax fibres into cotton fibres, while weak acid solutions do the reverse. Acids or alkalies are produced by the current in the fibre itself, and to effect this the pulp impregnated with a saline solution (and alkaline nitrate, acetate or sulphate), is passed between the revolving roller electrodes and along a sheet of felt, care being taken to place underneath the felt the roller on which form the elements which are not to act on the fibre. If it is required to give the flax fibres the properties of cotton fibres, the lower roller should be the anode and the upper the cathode, so that the pulp may be in contact with the nascent alkalies and the hydrogen. On the other hand, if it is desired to transform cotton pulp into flax pulp, the cathode is placed underneath the flax sheet, the moving pulp being exposed to the action of the acids, and oxygen formed at the anode. The manufacture of paper pulp from wood has also been proposed by Kellner. The disintegration and transformation of the pulp is carried out as follows:—The wood is cut up and impregnated with a slightly alkaline solution of sea salt, and is then placed in brick troughs, covered in with baked earth. In these troughs are placed the electrodes. When a current is passed the soda formed at the negative pole disintegrates the wood, while the chlorine and oxygen effectually bleaches the pulp. In the very latest methods employed by Kellner, he prepares the bleaching solution before hand, like M. Hermite. In his "electrolyser," Kellner employs zinc cathodes, and either carbon, platinum, or platinised porcelain for the anodes. The solution is sodium chloride (strength not given), to which is added a small quantity of a salt (salammoniac, sulphate, or nitrate of potassium), and it reaches the "electrolyser" at the bottom, and overflows at the top into the vessels containing the wood pulp. These latter are arranged so as to be heated, heat being efficacious in the preparation of wood pulp. The Kellner process is carried out amongst other places at some paper works established near a salt mine at Halleim, near Salzburg. Hydraulic power to the extent of nearly 800 horse-power is employed. The Kellner and Partington Company of Manchester have also constructed about a year since in Norway some wood pulp works. These works are situated in the district of Boregaard, on the right bank of the Glommen, close to the famous waterfall of Sarpfos. The head of water is about 19 metres (63 feet), and several thousand horse-power is available.

Another electrical process for producing bleaching chlorides is that of Andreoli. The electrolysis of a solution of sea salt is again the basis of the method; but Andreoli has a special device for diminishing the secondary reactions which, as a rule, limit its applicability to the production of bleaching agents. According to the inventor, this result is obtained by employing a certain number of anodes, and only two cathodes of small surface. The anodes are of retort carbon, and arranged as shown in Fig. 4. Each carbon is coppered at the top, then tinned and fixed in a copper cartridge-case like cylinders. The carbons so prepared are soldered to a copper bar, B B (Fig. 4), and all the metallic portion of the arrangement is covered with varnish or enamel. The remaining three sides of the frame A A A (Fig. 4) are of wood. Twenty frames of this kind, 60 to 80 centimetres high, and each containing 10 to 20 carbon rods, are arranged parallel to one another along a slate-lined trough, having a capacity of 50 litres (11 gallons). At each end of this trough there is a cathode of iron-wire gauze. These cathodes are placed between wooden boxes, and are 2 or 3 centimetres higher than the trough itself. These boxes, which are pierced with holes, are filled with binoxide of manganese, the object of which is to prevent the hydrogen liberated at the cathode from reducing the oxygen-chlorine compounds formed at the anode. The electrolyte has a density of 5deg. to 8deg. Baumé, and one gramme (15·4 grains) of carbonate of soda is added to every hundred litres (22 gallons). According to Andreoli, taking 20 50-litre troughs and a dynamo giving 1,000 amperes at 100 volts, the yield of chlorine in each trough (premising that 1 gramme of chloride is liberated per ampere-hour) would be 1 kilogramme of chlorine—that is to say, 20 grammes of chloride per litre of liquid (1386 grains per gallon), which corresponds to a 5deg. Baumé solution of chloride of lime. In practice, if this degree of concentration is immediately arrived at, we have heating

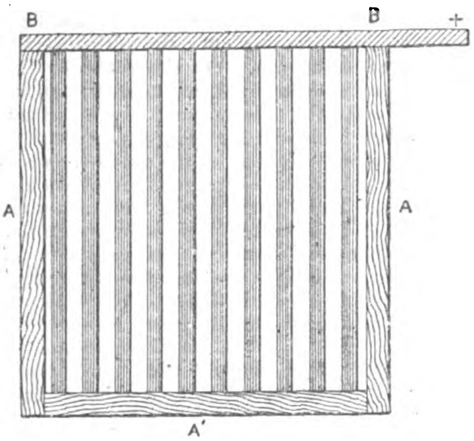

Fig. 4.

of the solution and the production of chlorates. The current, therefore, is only passed through the troughs for ten minutes at a time, until the strength of the solution is about 3 grammes per litre (about 70 grains per gallon). The vessels are arranged one above the other, so that there is constant circulation. In order to obtain a quantity of bleaching liquor equal to one ton of chloride of lime, 4,000 horse-power hours are required. If 1½kg. of coal is consumed per horse-power hour, the coal consumption for 4,000 horse-power hour will be 6 tons, and taking coal at 20fr., the cost of production is still less than one-half the price of a ton of chloride of lime. The Andreoli process is, we believe, worked by the London Electrical Bleaching Company.

Still, another electro-chemical method[23] consists in the electrolysis of a solution of 29kg. (64lb.) of calcined magnesia, 162kg. (356lb.) of hydrochloric acid (density 1·16), and 1,136 litres (250 gallons) of water; a solution in short of chloride of magnesium with excess of magnesia, since 164kg. of acid would be required to take up all the magnesia. After a current of 120 amperes at 6 volts has been passed through such a solution for 100 hours, it contains ·25 per cent. of active chlorine, and is capable of bleaching textiles without injuring them. The originality of the process lies chiefly in the material employed as electrodes. The cathodes are of sheet copper (68·5 × 45·75cms.); the anodes (18 × 10cms.) are of lithanode. The electrodes, to the number of 12, are arranged along the sides and at the bottom of the vessel, and are separated from the material to be bleached by wattle-work. The electrolysis, bleaching, and regeneration of the liquid are thus all carried out in the same bath.

In addition to the various electro-chemical methods mentioned above, M. Villon, in a recent issue of the *Revue de Chimie Industrielle et Agricole*, describes a process of bleaching paper pulp by ozone produced in the following manner. A box of hard wood is lined with glass slabs, and in this box, which is hermetically sealed, is placed a series of cells or partitions of glass. These cells or partitions are the exact height of the box, but 3 or 4cms. less in breadth, and they are filled with granulated lead or pieces of retort carbon. These cells are alternately connected to the + and − terminal of powerful induction coil. The space between the cells when the coil is at work is thus filled with sparks, and through this space oxygen cooled to 5°C. is forced, and is then passed out largely ozonised into the paper bleaching chambers. From the bleaching chambers the oxygen passes over sulphuric acid to dry it, and thence back again to the gasometer. Bleaching by ozone is quicker and more convenient than bleaching by chlorine, and the cellulose is not attacked. Taking the price of ozone at 75 centimes per cube metre (35·3 cube feet), the bleaching of 6 tons of pulp would cost 60fr. by this process, or 40 per cent. less than by the electro-chemical, and 70 cent. per less than by the old chloride of lime method.

The electrical preparation of bleaching agents is, it will thus be seen, rapidly becoming an established industry.

## GELATINOUS ELECTROLYTE FOR STORAGE BATTERIES.

REPORT BY PROF. W. KOHLRAUSCH.

During the last year an experimental research both of a theoretical and practical nature has been made by Prof. Dr. W. Kohlrausch, of the University of Hanover. The following is a translation of the opinion of this electrician:—

Since April 21st of this year I have made experiments with accumulator cells of the "Maschinenfabrik Oerlikon" (Dr. P. Schoop's patent), the result of which I have the honour to communicate to you.

The tests were made with a view to ascertain the behaviour of the accumulators if subjected to rough usage. For this reason severe tests were followed by regular tests with ordinary currents, in order to get an opinion as to the damage actually done by the severe handling. After a series of regular charges and discharges the cells were finally charged, and remained idle for a month. In charging the cells again 52 ampere-hours were absorbed, but a strong development of gases occurred at the end of the charging period. The whole capacity (in charging with 10 amperes) being 73 ampere-hours, it is obvious that about five-sevenths of the former charge seems to have disappeared during the rest of thirty days. Probably a part of this lost energy has been used up in a certain chemical or physical transformation of the active material, perhaps to the advantage of the accumulator.

A normal discharge and charge were now made, and it proved that the cells were still in good working order. The discharge amounted to 72 ampere-hours, indicating an increase of the capacity, the former trials having given only 65 ampere-hours in the average. (The makers claim 70 ampere-hours as a normal discharging capacity.)

Again, the same cells were discharged with the normal rate of current to, say, 9 amperes. After the discharge of about 73 ampere-hours, the current decreased and could only be maintained by decreasing the external resistance of the circuit; at last the cells were short-circuited in order to get the last energy out of the accumulators. In this way, again, 36 ampere-hours were drawn out, and the whole discharge was 109 ampere-hours. The cells were now charged with only 6 amperes (too weak a current) until gas bubbles were developed, and soon afterwards (after 1½ hours' rest) discharged with a current of 50 amperes—that is to say, five times the normal rate of discharging current.

The capacity was 41·6 ampere-hours, about four-sevenths of the normal capacity. It is a well-known fact that the capacity decreases if the discharging current increases.

Again, the accumulators were charged at the normal rate of current, and discharged with the normal current, 68·2 ampere-hours; charging and discharging was in every sense normal.

The discharged cells were now charged in the reversed direction of the current with 124 ampere-hours; the electro-chemical reactions on the plates were exchanged to, say, the former cathode was anode, and the former anode had become cathode; at the end the pressure of the cells was again two volts, but in the reversed sense of current.

During this trial at first 68·2 ampere-hours had passed the plates "voluntarily" in the direction as the discharging current, afterwards 124 ampere-hours had passed "involuntarily," together 192 ampere hours.

Now, the accumulators were again charged with 9 amperes (in the former right sense), and after 223 ampere-hours the cells were

Digitized by Google

again fully charged, and began to develop gases. During this forced charging and discharging the efficiency was still 86 per cent. (the efficiency under normal conditions being 89 per cent.) in ampere-hours.

The following discharge with 9 amperes yielded 68·3 ampere-hours; it is obvious that this series of abnormal tests did not at all decrease the working and capacity of the cells; the capacity increased rather a little. I think that during the long rest of the cells, probably also during this abnormal treatment, parts of the active material have been powerfully excited; parts which had before not worked electrically have been transformed into true active material.

One of the cells was now taken to pieces, and I saw that with the gelatinous electrolyte the whole construction of the cell was of a remarkable rigidity and constancy. The two sections of plates could only be separated with considerable force after a previous softening of the gelatine. After the plates had been fully cleaned from the gelatine it looked perfectly normal, just as before the trials. The grids are very thin and soft, but it is for this reason that I think it "improbable that plates can buckle." The stiff gelatine could not easily be removed by those soft plates in order to touch each other (short-circuiting), an inconvenience too often observed in other cells with thin plates and narrow distances between the plates. Falling or dropping of the active material off the plates is made impossible by the gelatine; also it is improbable that active material could penetrate through this gelatine.

The most important question now is that of the durability of those cells. Of course it is only possible after a longer time, at least a year or two, to give an opinion. How long will the thin grid of lead resist the combined action of the electrical and chemical changes within the electrodes? How long will it take to have the metallic support eaten up by a daily action of the cells, until the whole grid is converted into the same active material, which does only practical working, if embedded in a perfect metallic conductor? I have oberved on other systems with thin plates, that often the grid becomes brittle and breaks; again, a practical trouble with accumulators. I would say that the grids of the plates may last a year or two in daily use, but it is possible that the cells will only cease to give daily practical service after three to five years. I hope to have a more exact opinion in this direction after I shall have used the cells for another longer time, say a year or two. The present trials have shown that these cells endure an abnormal and very bad treatment in a very satisfactory manner indeed, and that this accumulator is a practical apparatus.

APPENDIX BY DR. PAUL SCHOOP.

The following data about the tested cells may be added:—

| | | |
|---|---|---|
| Number of plates | 17 | |
| Weight of plate | 8ko. | Total weight 11·7ko. |
| „ of electrolyte | 3ko. | |
| „ of ebonite box | 0·7ko. | |
| Box—Length | 125mm. | |
| „ Breadth | 160mm. | |
| „ Height | 205mm. | |
| Total height of cell | 250mm. | |
| Capacity (in discharging) | 70 ampere-hours. | |
| Strength of current | 9 to 10 amperes. | |

This cell represents the smallest type of cells, made especially for portable work, electric cars, and railway lighting.

During the last months, *The Electrician* twice mentioned the "gelatinous electrolyte" (August 12th and September 10th). In the August issue the mode of making the gelatine was described, together with a comparison of a cell filled with ordinary dilute acid and filled with gelatine. In the September issue was a translation of an experimental research of Dr. Kapp (Prof. Weber, University, Zürich), at first published in *La Lumière Electrique*. This latter publication has given most valuable light regarding the internal resistances of the cells. Perhaps it may be interesting to look a little deeper into what is called internal resistance.

This resistance is composed of:—

1st. Resistance of the electrolyte (the fluid or gelatinous dilute sulphuric acid).

2nd. Resistance of the grids (the metallic conductor, on which the spongy active materials are placed or adhere).

3rd. Resistance of the spongy material on the negative plate (cathode), saturated with dilute sulphuric acid.

4th. On the positive plate (anode), saturated with dilute acid.

5th. Resistance of the layer between the metallic grid (support) and the spongy material on the cathode.

6th. Resistance of the layer between the metallic grid (support), and the spongy material on the cathode.

Only the second named resistance is approximately constant during a trial of the accumulator; all other resistances may vary with the strength of current, with the condition of the cell, if more or less charged or discharged, with the temperature and with impurities of the materials. It is highly interesting to compare a Planté accumulator (a cell, the plates of which have been treated purely electrically in dilute sulphuric acid, until a certain capacity has been obtained) with a so-called "pasted" accumulator (Faure). Suppose the surface of the electrodes of a Planté cell and a "pasted" cell be the same, also the quantity of spongy or active material be the same, the acid the same, and the strength of current, it will be found that the internal resistance of the Planté cell is considerably less, about only one-third of what it is in the "pasted" cell.

It is very likely that the future accumulator will be made again without mechanical application of materials, but that the Planté process will be tried again with the view of obtaining a process of electrical formation which enables us to get within a short time, with less cost, a solid accumulator with a practical capacity.

## THE ELECTRO-MAGNET.*

BY PROFESSOR SILVANUS P. THOMPSON

(*Continued from page 20.*)

A rough and ready rule sometimes given for the size of wire is to allow $\frac{1}{1000}$ square inch per ampere. This is an absurd rule, however, as the figures in the table show. Under the heading 1,000 amperes to square inch, it appears that if a No. 18 S.W.G. wire is used, it will at that rate carry 1·81 amperes; that if there is only one layer of wire, it will only warm up 4·64°Fahr., consequently one might wind layer after layer to a depth of 3·3in. without getting up to the limit of allowing one square inch per watt for the emission of heat. In very few cases does one want to wind a coil so thick as 3·3in. For very few electro-magnets it is needful that the layer of coil should exceed ½in. in thickness; and if the layer is going to be only ½in. thick, or about $\frac{1}{7}$ of the 3·3, one may use a current density $\sqrt{7}$ times as great as 1,000 amperes per square inch, without exceeding the limit of safe working. Indeed, with coils only ½in. thick, one may safely employ a current density of 3,000 amperes per square inch, owing to the assistance which the core gives for the dissipation and emission of heat.

Suppose, then, we have designed a horse-shoe magnet, with a core 1in. in diameter, and that after considering the work it has to do, it is found that a magnetising power of 2,400 turns is required; suppose also that it is laid down as a condition that the coil must not warm up more than 50°F. above the surrounding air—what volume of coil will be required? Assume first that the current will be 1 ampere; then there will have to be 2,400 turns of a wire which will carry 1 ampere. If we took a No. 20 S.W.G. wire, and wound it to a depth of ½in., that would give 220 turns per inch length of coil; so that a coil 11in. long, and a little over ⅜in. deep (or 10 layers deep) would give 2,400 turns. Now Table X. shows that if this wire were to carry 1·018 ampere, it would heat up 225° Fahr., if wound to a depth of 3·9in. If wound to ½in., it would, therefore, heat up to 30° Fahr.; and with only 1 ampere would, of course, heat less. This is too good; try the next thinner wire. No. 22 S.W.G. wire, at 2,000 amperes to square inch, will carry 1·23 amperes; and heats 225° if wound up 1·13in. If it is only to heat 50° it must not be wound more than ¼in. deep; but if it only carries current of 1 ampere it may be wound a little deeper—say to 14 layers. There will then be wanted a coil about 7in. long to hold the 2,400 turns. The wire will occupy about 3·85 square inches of total cross section; and the volume of the space occupied by the winding will be 26·95 cubic inches. Two bobbins, each 3½in. long and ·65 deep, to allow for 14 layers, will be suitable to receive the coils.

By the light of the knowledge one possesses as to the relation between emissivity of surface, rate of heating by current, and limiting temperatures, it is seen how little justification there is for such empirical rules as that which is often given, namely, to make the depth of coil equal to the diameter of the iron core. Consider this in relation to the following fact: that in all those cases where leakage is negligible, the number of ampere-turns that will magnetise up a thin core to any prescribed degree of magnetisation will magnetise up a core of any section whatever, and of the same length, to the same degree of magnetisation. A rule that would increase the depth of copper proportionately to the diameter of the iron core is absurd.

Where less accurate approximations are all that is needed, more simple rules can be given. Here are two cases:—

*Case* 1.—*Leakage Assumed to be Negligible.*—Assume $B = 16{,}000$, then $H = 50$ (*see* Table III.). Hence the ampere-turns per centi-

* A series of four Cantor Lectures delivered before the Society of Arts, January—February, 1890.

Digitized by Google

metre of iron will have to be 40, or per inch of iron, 102; for H is equal to 1·2566 times the ampere-turns per centimetre. Now if the winding is not going to exceed ½in. in depth, we may allow 4,000 amperes per square inch without serious over-heating. And the 4,000 ampere-turns will require 2in. length of coil, for each inch of coil carries 2,000 ampere-turns without over-heating. Hence each inch of coil ½in. deep will suffice to magnetise up 20in. length of iron to the prescribed degree.

*Case* 2.—*Leakage Assumed to be 50 per cent.*—Assume B in air-gap = H = 8,000, then to force this across requires ampere-turns 6,400 per centimetre of air, or 16,250 per inch of air. Now if winding is not going to exceed ½in. depth, each inch length of coil will carry 2,000 ampere-turns. Hence, 8in. length of coil ½in. deep will be required for 1in. length of air, magnetised up to the prescribed degree.

WINDINGS FOR CONSTANT PRESSURE AND FOR CONSTANT CURRENT.

In winding coils for magnets that are to be used on any electric light system, it should be carefully borne in mind that there are separate rules to be considered according to the nature of the supply. If the electric supply is at *constant pressure*, as usual for glow lamps, the winding of coils of electro-magnets follow the same rule as the coils of voltmeters. If the supply is with *constant current*, as usual for arc lighting in series, then the coils must be wound with due regard to the current which the wire will carry, when lying in layers of suitable thickness, the number of turns being in this case the same whether thin or thick wire is used.

If we assume that a safe limit of temperature is 90° Fahr. higher than the surrounding air, then the largest current which may be used with a given electro-magnet is expressed by the formula:—

$$\text{Highest permissible amperes} = 0{\cdot}63\sqrt{\frac{s}{r}}$$

where $s$ is the number of square inches of surface of the coils, and $r$ their resistance in ohms.

Similarly for coils to be used as shunts, we have

$$\text{Highest permissible volts} = 0{\cdot}63\sqrt{sr}.$$

The magnetising power of a coil, supplied at a given number of volts of pressure, is independent of its length, and depends only on its gauge, but the longer the wire the *less* will be the heat waste. On the contrary, when the condition of supply is with a constant number of amperes of current, the magnetising power of a coil is independent of the gauge of the wire, and depends only on its length; but the larger the gauge the less will be the heat waste.

MISCELLANEOUS RULES ABOUT WINDING.

To reach the same limiting temperature with bobbins of equal size wound with wires of different gauge, the cross-section of the wire must vary with the current it is to carry; or, in other words, the current-density (amperes per square inch) must be the same in each. Table X. shows the amperages of the various sizes of wires, at four different values of current-density.

To raise to the same temperature two similarly-shaped coils, differing in size only, and having the gauges of the wires in the same ratio (so that there are the same number of turns on the large coil as on the small one), the currents must be proportional to the square roots of the cubes of the linear dimensions.

Sir William Thomson has given a useful rule for calculating windings of electro-magnets of the same type but of different sizes. Similar iron cores, similarly wound with lengths of wire proportional to the squares of their linear dimensions, will, when excited with equal currents, produce equal intensities of magnetic field at points similarly situated with respect to them.

Similar electro-magnets of different sizes must have ampere-turns proportional to their linear dimensions if they are to be magnetised up to an equal degree of saturation.

It is curious what erroneous notions crop up from time to time about winding electro-magnets. In 1869 a certain Mr. Lyttle took out a patent for winding the coils in the following way. Wind the

Figures in columns marked A signify number of amperes the wire carries.

Figures in columns marked F signify number of degrees (Fahrenheit) that the coil will warm up if there is only one layer of wire, and on the assumption that the heat is radiated only from the outer surface of the coil: they are calculated by the following modification of Forbes's rule:—

Rise in temperature (Fahrenheit degrees) = 225 × No. of watts lost per square inch.

= 159 × sectional area × number of turns to 1in. (at 1,000 amperes per sq. in.).

Figures in columns marked D are the depths in inches to which wire may be wound if 1 watt be lost by each square inch of radiating surface, the outside radiating surface of the bobbin being only considered.

Rule for calculating a 7-strand cable:—Diameter of cable = 1·134 × diameter of equivalent round wire.

Figures under heading "Turns to 1 linear inch" are calculated for cotton-covered wires of average thicknesses of coverings used for the different gauges, viz., 14 mils. additional diameter on round wires (from No. 22), and 20 mils. on stranded or square wire.

Figures under heading "Turns per square inch" are calculated from preceding, allowing 10 per cent. for bedding of layers.

Resistance (ohms) of coil of copper wire, occupying $v$ cubic inches of coil-space, and of which the gauge is $d$ mils. uncovered, and D mils. covered, may be approximately calculated by the rule:—

$$\text{Ohms} = 960{,}700\frac{v}{D^2\,d^2}.$$

The data respecting sizes of wires of various gauges are kindly furnished by the London Electric Wire Company.

Digitized by Google

first layer as usual, then bring the wire back to the end where the winding began, and wind a second layer, and so on. In this way all the windings will be right-handed or else all left-handed, not alternately right and left as in the ordinary winding. Lyttle declared that this method of winding a coil gave more powerful effects; so did M. Brisson, who re-invented the same mode of winding in 1873, and solemnly described it. Its alleged superiority was at once disproved by Mr. W. H. Preece, who found the only difference to be that there was more difficulty in carrying out this mode of winding

Another popular error is that electro-magnets in which the wires are badly insulated are more powerful than those in which they are well insulated. This arose from the ignorant use of electro-magnets having long thin coils (of high resistance) with batteries consisting of a few cells (of low electromotive force). In such cases, if some of the coils are short-circuited, more current flows, and the magnetising power may be greater. But the scientific cure is either to re-wind the magnet with an appropriate coil of thick wire, or else to apply another battery having an electromotive force that is greater.

### Specifications of Electro-magnets.

One frequently comes across specifications for construction which prescribe that an electro-magnet shall be wound so that its coil shall have a certain resistance. This is an absurdity. Resistance does not help to magnetise the core. A better way of prescribing the winding is to name the ampere-turns and the temperature limit of heating. Another way is to prescribe the number of watts of energy which the magnet is to take. Indeed, it would be well if electricians could agree upon some sort of figure of merit by which to compare electro-magnets, which should take into account the magnetic output—*i.e.*, the product of magnetic flux into magnetomotive force—the consumption of energy in watts, the temperature rise, and the like.

### Amateur Rule about Resistance of Electro-magnet and Battery.

In dealing with this question of winding copper on a magnet core, I cannot desist from referring to that rule which is so often given, which I often wish might disappear from our text-books—the rule which tells you in effect that you are to waste 50 per cent. of the energy you employ. I refer to the rule which states that you will get the maximum effect out of an electro-magnet if you so wind it that the resistance is equal to the resistance of the battery you employ; or that if you have a magnet of a given resistance you ought to employ a battery of the same resistance. What is the meaning of this rule? It is a rule which is absolutely meaningless unless in the first case the volume of the coil is prescribed once for all, and you cannot alter it, or unless once for all the number of battery elements that you can have is prescribed. If you have to deal with a fixed number of battery elements, and you have to get out of them the biggest effect in your external circuit, and cannot beg, buy, or borrow any more cells, it is perfectly true that, for steady currents, you ought to group them so that their internal resistance is equal to the external resistance that they have to work through; and then, as a matter of fact, half the energy of the battery will be wasted, but the output will be a maximum. Now that is a very nice rule indeed for amateurs, because an amateur generally starts with the notion that he does not want to economise in his rate of working; it does not matter whether the battery is working away furiously, heating itself, and wasting a lot of power; all he wants is to have the biggest possible effect for a little time out of the fewest cells. It is purely an amateur's rule, therefore, about equating the resistance inside to the resistance outside. But it is absolutely fallacious to set up any such rule for serious working; and not only fallacious, but absolutely untrue if you are going to deal with currents that are going to be turned off and on quickly. For any apparatus like an electric bell, or rapid telegraph, or induction coil, or any of those things where the current is going to vary up and down rapidly, it is a false rule, as we shall see presently. What is the real point of view from which one ought to start? I am often asked questions by, shall I say, amateurs as well as by those who are not amateurs, about prescribing the battery for a given electro-magnet, or prescribing an electro-magnet for a given battery. Again, I am often told of cases of failure in which a very little common sense rightly directed might have made a success. What one ought to think about in every case is not the battery, not the electro-magnet, but *the line*. If you have a line, then you must have a battery and electro-magnet to correspond. If the line is short and thick, a few feet of good copper wire, you should have a short thick battery (a few big cells, or one big cell), and a short thick coil on your electro-magnet. If you have a long thin line, miles of it, say, you want a long thin battery (small cells, and a long row of them) and a long thin coil. That is then our rule; for a short thick line, a short thick battery, and a short thick coil; for a long thin line, a long thin battery; and electro-magnet coils to match. You smile: but it is a really good rule that I am giving you; vastly better than the worn-out amateur rule.

But, after all, my rule does not settle the whole question, because there is something more than the whole resistance of the circuit to be taken into account. Whenever you come to rapidly-acting apparatus, you have to think of the fact that the current, while varying, is governed not so much by the resistance as by the inertia of the circuit—its electro-magnetic inertia. As this is a matter which will claim our especial attention hereafter, I will leave battery rules for the present, and proceed with the question of design.

### Forms of Electro-magnets.

This at once leads us to consider the classification of forms of magnets. I do not pretend to have found a complete classification. There is a very singular book written by Mons. Nicklès, in which he classifies under 37 different heads all conceivable kinds of magnets, bidromic, tridomic, mononemic, multidromic, and I do not know how many more; but the classification is both unmeaning and unmanageable. For my present purposes I will simply pick out those which come under three or four heads, and deal separately with others that do not quite fit under any of the four categories.

*Bar Electro-magnets.*—In the first place there are those which have a straight core, of which there are several specimens on the table here.

*Horse-shoe Electro-magnets.*—Then there are the horse-shoes, of which some are of one piece bent, and others are of the more frequent shape, made of three pieces.

*Iron-clad Electro-magnets.*—Then from the horse-shoes I go to those magnets in which the return circuit of the iron comes back outside the coil either from one end or the other, or from both ends, sometimes in the form of an external tube or jacket, sometimes merely with a parallel return yoke, or two parallel return yokes.

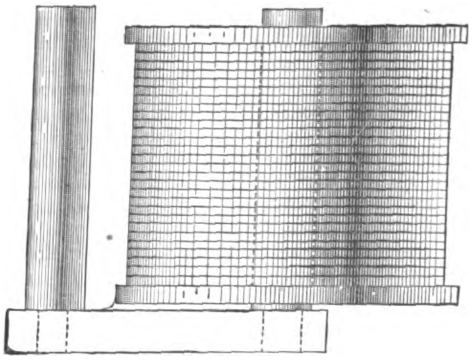

Fig. 50.—Club-footed Electro-magnet.

All such magnets I propose to call—following the fashion that has been adopted for dynamos—iron-clad electro-magnets. One of them, the jacketed electro-magnet, is shown in Fig. 12, and there are others not so well known. There is one used by Mr. Cromwell Varley, in which a straight magnet is placed between a couple of iron caps, which fit over the ends, and virtually bring the poles down close together; the circular rim of one cap being the north pole, and that of the other cap being the south pole, the two rims being close together. That plan of course produces a great tendency to leak across from one rim to the other all round. The advantages, as well as the disadvantages, of the jacketed magnet I alluded to in my last lecture, when I pointed out to you that for all action at a distance it is far better not to have an iron-clad return path, whereas for action in contact the iron-clad magnet was distinctly a very good form. In one form of iron-clad magnet the end of the straight central core is fixed to the middle of a bar of iron, the ends of which are bent up and brought flush with the top of the bobbin, making thus a tripolar magnet, with one pole between the other two. The armature in this form is a bar which lies right across the three poles. There is an example of this excellent kind of electromagnet applied in one of the forms of electric bell indicator made by Messrs. Gent, of Leicester.

Then besides these three main classes—the straight bar, the horse-shoe, and the iron-clad—there is another form which is so useful, and so commonly employed in certain work, that it deserves to have a name of its own. It is that called by Count Du Moncel the *aimant boiteux*, or club-footed magnet (Fig. 50). It is a horse-shoe, in fact, with a coil upon one pole and no coil upon the other. The advantage of that construction is simply, I suppose, that you will save labour—you will only have to wind the wire on one pole instead of two. Whether that is an improvement in any other sense is a question for experiment to determine; but on which theory perhaps might now be able to say something.

Digitized by Google

Count Du Moncel, who made may experiments on this form of magnet, ascertained that there was for an equal weight of copper a slight falling off in power with the club-footed magnet. Indeed one might almost predict, for a given weight of copper, if you wound all in one coil only, you will not make as many turns as if you wound it in two; the outer turns on the coil being so much larger than the average turn when wound in two coils. Consequently the number of ampere-turns with a given weight of copper would be rather smaller, and you would require more current to bring the magnetising power up to the same value as with the two coils. At the same time the one coil may be produced a little more cheaply than the two; and indeed such electromagnets are really quite common, being largely used, for the sake of cheapness and compactness, in indicators of electric bells.

Du Moncel tried various experiments about this form to find whether it acted better when the armature was pivotted over one pole or over the other, and found it worked best when the armature was actually hinged on to that pole which comes up through the coil. He made two experiments, trying coils on one or other limb, the armature being in each case set at an equal distance. In one experiment he found the pull was 35 grammes, with an armature hinged on to the idle pole, and 40 grammes when it was hinged on to the pole which carried the coil.

Another form of electromagnet, having but one coil, is used in the electric bells of church-bell pattern, of which Mr. H. Jensen is the designer. In Jensen's electromagnet a straight cylindrical core receives the bobbin for the coil, and, after this has been pushed into its place, two ovate pole-pieces are screwed upon its ends, serving thus to bring the magnetic circuit across the ends of the bobbin, and forming a magnetic gap along the side of the bobbin. The armature is a rectangular strip of soft iron, about the same length as the core, and is attracted at one end by one pole-piece, and at the other end by the other.

### Effect of Size of Coils.

Seeing that the magnetising power which a coil exerts on the magnetic circuit which it surrounds is simply proportional to the ampere-turns, it follows that those turns which lie on the outside layers of the coil, though they are further away from the iron core, possess precisely equal magnetising power. This is strictly true for all closed magnetic circuits; but in those open magnetic circuits where leakage occurs it is only true for those coils which encircle the leakage lines also. For example, in a short bar electro-magnet, of the wide turns on the outer layer, those which encircle the middle part of the bar do enclose all the magnetic lines, and are just as operative as the smaller turns that underlie them; whilst those wide turns which encircle the end portions of the bar are not so efficient, as some of the magnetic lines leak back past these coils.

### Effect of Position of Coils.

Among the other researches which Du Moncel made with respect to electro-magnets, was one on the best position for placing the coil upon the iron core. This is a matter that other experimenters have examined. In Dub's book, "Electromagnetismus," to which I have several times referred, you will also find many experiments on the best position of a coil; but it is perhaps sufficient to narrate a single example. Du Moncel had four pairs of bobbins made of exactly the same length, and with 50 metres of wire on each, one pair was 16 centimetres long, another pair 8 centimetres, or half the length, with not quite so many turns, because, of course, the diameter of the outer turns was larger, one 4 centimetres in length and another 2 centimetres. These were tried both with bar magnets and horse-shoes. It will suffice, perhaps, to give the result of the horse-shoe. The horse-shoe was made long enough—16 centimetres only, a little over 6in. long—to carry the longest coil. Now when the compact coils 2 centimetres long were used, the pull on the armature at a distance away of 2 millimetres (it was always the same, of course, in the experiments) was 40 grammes. Using the same weight of wire, but distributed on the coils twice as long, the pull was 55 grammes. Using the coils 8 centimetres long, it was 75 grammes; and using the coils 16 centimetres long, covering the length of each limb, the pull was 85, clearly showing that, where you have a given length of iron, the best way of winding a magnet to make it pull with its greatest pull is not to heap the coil up against the poles, but to wind it uniformly, for this mode of winding will give you more turns, therefore more ampere-turns, therefore more magnetisation. An exception might, however, occur in some case where there is a large percentage of leakage. With club-footed magnets results of the same kind are obtained. It was found in every case that it was well to distribute the coil as much as possible along the length of the limb. All these experiments were made with a steady current. It does not follow, however, because winding the wire over the whole length of core is best for steady currents that it is the best winding in the case of a rapidly varying current; indeed, we shall see that it is not.

*(To be continued.)*

## LONDON CHAMBER OF COMMERCE.

### MEETING OF THE ELECTRICAL TRADES' SECTION COMMITTEE.

A meeting of the Committee of the Electrical and Allied Trades' Section of the London Chamber of Commerce was held on Monday last at Botolph House, Eastcheap, under the presidency of Mr. R. E. Crompton (Chairman of the Committee). Amongst those present were Major Flood-Page and Messrs. Garcke, Swinburne, Erskine, Reeves, and Price. The minutes of the last meeting having been read by the Secretary of the Chambor (Mr. Kenric B. Murray,

The CHAIRMAN said that the first item on the agenda paper was the Board of Trade Rules. The committee was aware that four firms had memorialised the Board of Trade with a view of getting that department to introduce reasonable modifications into its "Regulations and Conditions for Securing the Safety of the Public, and for ensuring a proper and sufficient supply of Electrical Energy," and he suggested that a similar memorial be now sent to the Board of Trade by the Committee. Rule 33 of the New Rules was the one which appeared to him to be the most open to objection; indeed, as it stood, it was practically unworkable. This rule stipulated that:—"Every high-pressure aerial conductor shall be continuously insulated with a durable and efficient material to be approved by the Board of Trade, to a thickness of not less than one-tenth part of an inch; and in cases where the extreme difference of potential in the circuit exceeds 2,000 volts, the thickness of insulation shall not be less in inches or parts of an inch than the number obtained by dividing the number expressing the volts by 20,000. This insulation shall be further efficiently protected on the outside against injury or removal by abrasion. If this protection be wholly or partly metallic it shall be efficiently connected to earth." Such conductors, even for the smallest working current, could not be produced for less than £78 per mile, while a well-insulated conductor of the ordinary character could be turned out for £28 per mile. This meant a difference of several thousands of pounds to those engaged in running overhead wires. Rule 35, which ran as follows, was also open to objection:—"Every aerial high-pressure conductor shall be efficiently suspended by means of non-metallic ligaments to suspending wires, so that the weight of the conductor does not produce in it any sensible stress in the direction of its length, and the insulated conductors and suspending wires, where attached to supports, shall be in contact only with material of highly insulating quality, and shall be so attached and guarded, that in case they break away it shall not be possible for them to fall away clear of the support." He was of opinion that this was a case in which the section might well do its best to prevent the progress of the industry from being seriously hindered. The Council of the Institution of Electrical Engineers, so far as he could make out, were not inclined to take any steps in this matter until asked to by the Board of Trade.

In answer to a question by Major Flood-Page the CHAIRMAN said that the Board of Trade conductor was not, so he was assured by the Silvertown people, as safe as an ordinary insulated overhead wire.

Several gentlemen pointed out that the great thickness of the insulation rendered the centrality of the conductor very uncertain, moreover it was proposed to suspend this abnormally massive cable from leather or other similar ligaments which the weather would quickly rot away.

Major FLOOD-PAGE thought that if it could be brought home to the Board of Trade that their proposed overhead conductor, was, as a matter of fact, less safe than an ordinary overhead conductor, common sense would lead the department to revise its rules.

Mr. SWINBURNE pointed out that other rules than those referred to by the Chairman required revision. Thus rule 18 stipulated that transformers on the consumers' premises should be "completely enclosed in solid walls or in strong metal casing. . . ." The latter proviso affected the use of open-circuit transformers. He thought that the memorial should contain references to all the objectionable points in the rules.

Mr. GARCKE was astonished that such rules should have been framed without consultation with the trade.

Major FLOOD-PAGE suggested that perhaps the best course to take would be to pass a resolution to be forwarded to the Board of Trade asking them in the interest of the electrical industry to refer their rules again to the Council of the Institution of Electrical Engineers. The Committee might then ask the Council of the Institution to consider the matter together with them.

A discussion ensued, in the course of which it was pointed out that the previous communication of the Section to the Board of Trade on this subject had not received a very satisfactory reply (*The Electrician*, August 8, 1890, p. 385). The letter of the Board of Trade was then read by the Secretary, and it was unanimously resolved that the Chairman should be requested to bring the whole question before the general council of the Chamber at its next meeting, with a view of getting the Council to move in the matter, as one of a general trade interest.

Mr. GARCKE then brought forward the question of the Correspondent's duties. The matter, he said, had been left in the hands of the Chairman, Major Flood-Page and himself, and they, in conjunction with Mr. Murray, had gone very carefully into it. The outcome of their consultations was the following proposal:—That the Chairman and Vice-Chairman should be constituted into a sort of working executive committee. If the Chamber of Commerce could lend this sub-committee a little clerical assistance he thought its work would not trench unduly on the time of his colleagues and himself. If

Digitized by Google

this idea met with the approval of the Committee, the Section would possess an executive empowered to take prompt action in its name. The executive committee would, of course, report at every monthly meeting of the general committee.

Major FLOOD-PAGE pointed out that the Section was at present practically without an executive, hence many opportunities slipped by them for forwarding their general interests.

On the motion of Mr. PRICE, seconded by Mr. SWINBURNE, it was unanimously resolved to accept the admirable proposal of Mr. Garcke.

The CHAIRMAN then brought forward his scheme for the interchange of useful information. A circular letter had been prepared, also a couple of tables. He had devoted much time to the drawing up of the tables, and he now proposed that the letter and tables should, in the first instance, be sent to all the members of the Section for further suggestions, and with a view of gauging the probable amount of support the scheme would meet with; they could then be sent to electricians all over the world. The letter was then read, and copies of the tables distributed to those present.

Major FLOOD-PAGE thought that the Committee could hardly do better than agree to the letter and tables being sent out as a feeler. He begged to move that they be printed and circulated among all the members of the Section. The motion was agreed to.

Major FLOOD-PAGE said he hoped he was in order in referring to something not on the Agenda Paper; perhaps it would come under the head of "Other Matters," but he would like to know what was being done by those interested with regard to the Board of Trade form of accounts. It was really a very important question.

Mr. ERSKINE said that the supply company that he was connected with had been recently informed that the Board of Trade had a new form under consideration. The new form had not as yet been issued. One point with regard to these accounts was, he thought, worth calling attention to. The Board of Trade was proposing to make the supply companies write off depreciation on everything. Now, the water companies', and he thought the gas companies' plant was at its full value on their books, and a renewal account was kept up, depreciation only being written off works on leasehold property. The bearing of this on the question of purchase by local authorities was obvious.

After a few remarks by the Chairman on the valuable services recently rendered by the Chamber in preventing the formation of a monopoly in the Para rubber trade, the meeting terminated.

---

**The following is a copy of the circular letter and tables drawn up by Mr. Crompton :—**

*To the* SECRETARY *or* GENERAL MANAGER,

—— ———— *Lighting Company.*

DEAR SIR,—We shall be glad if you will bring before your Board of Directors or Board of Management (as the case may be) the following matter.

A great many English electrical engineers believe that the progress of the industry would be more rapid if there were, among the electrical engineers of all countries, a fuller interchange of ideas, and a freer publication of the data which are obtained in the practical working out of many of the great electrical problems which every day present themselves to us. It has been proposed at a meeting of the Electrical Section of the London Chamber of Commerce that steps should be taken to ascertain whether it is not possible to obtain mutual benefit from publication and circulation of a quarterly report compiled from data furnished not only from the various electrical manufacturers and electrical supply companies in the United Kingdom, but from those of the whole world, so far as it is possible to obtain them. In order to carry this out, it is thought that a start should be made in London by the Electrical Section of the London Chamber of Commerce, who would seek to add to their members as many foreign corresponding members as possible. With this end in view, I beg to ask you whether your Company would become members of such an international society. The terms of membership would be :—

(1.) A small subscription to meet the cost of printing, postage, &c.;

(2.) The members would be required to communicate to the head offices in London, from time to time, a correspondence letter giving in general terms the progress of the industry;

(3.) The members would be required to fill in, as far as they could do so without injury to themselves, on forms which should be from time to time furnished to them, the cost of production of electrical energy for lighting and power in a tabulated form under the various headings of material, labour, superintendence, wear and tear, renewals, and the other charges which go to make up the cost of production. In return for this they would each receive a copy of the quarterly report, in which would be added the whole of these correspondence letters, and the whole of the tabulated data.

We may add that the great steel industry of England and America, and on the continent, was very greatly benefited by a similar course in the early days of the Iron and Steel Institute, who took great pains to tabulate the results of blast furnaces, Bessemer convertors and such kinds of apparatus, and there is no doubt that enormous benefits accrued to that industry, from the study and comparison of the data obtained and circulated by means of the journal of the Iron and Steel Institute.

**Table I.**—*Efficiency at Varying Load Factors.*

| —— | A | B | C | D |
|---|---|---|---|---|
| Evaporative duty of boilers in pounds of water per pound of fuel ........ | ... | ... | ... | .. |
| Duty of engines in pounds of steam per I.H.P per hour ........ | ... | ... | ... | ... |
| Steam-engine efficiency or B.H.P. / I.H.P. | ... | ... | ... | ... |
| Dynamo efficiency or E.H.P. at terminals / B.H.P. of engines ... | ... | ... | ... | ... |
| Total generating efficiency or E.H.P. of dynamo / I.H P. of engines ...... | ... | ... | ... | ... |
| Distribution efficiency or E.H.P. deliv. to users... / E.H.P. at terminals ... | ... | ... | ... | ... |
| Total efficiency or E.H.P. deliv. to users... / I.H.P. of engines ...... | ... | ... | ... | ... |
| Load factor ........ | 100 | ... | ... | ... |

A. The figures for this column are those that have been obtained by actual test at trial runs at full power a sufficient number of hours to show that some results could be obtained from plant if run continuously the year round at full power. The 25 per cent. reserve plant being considered sufficient to allow every part of plant to be repaired and kept in thorough order. As such a condition has never yet been obtained in practice, of course, all figures must be calculated.

B. Figures from 12 months continuous working taken from the monthly or annual account of coal, water, and other materials used.

C. These figures to be the same as B, but for one month of heaviest load.

D. Same, for one month of lightest load.

By load factor is meant the relation which the actual output delivered to users bears to the actual output if plant were worked continuously throughout the year at its highest observed power. The factor for column A being 100.

For example: If the plant after allowing 25 per cent. for extra or reserve machinery is capable of delivering electrical energy to the consumer at the rate of 133 electrical horse-power, that is, 100 units per hour, or 8,760 hours × 100 = 876,000 units per annum. Then if the actual demand reached this figure, the load factor for columns B and A would be 100. But if the annual demand were 96,000 units, of which 12,000 was for December and 4,C00 for July, the load factors for B C D would be 11, 16·4, and 5·5 respectively.

**Table II.**—*Costs.*

| —— | B | | | C | | | D | | |
|---|---|---|---|---|---|---|---|---|---|
| | Per I. H. P. | Per Unit Generated. | Per Unit Sold. | — | — | — | — | — | — |
| Fuel ........ | ... | ... | ... | ... | ... | ... | ... | ... | ... |
| Water ........ | ... | ... | ... | ... | ... | ... | ... | ... | ... |
| Petty stores ........ | ... | ... | ... | ... | ... | ... | ... | ... | ... |
| Repairs and renewals of generating plant (inside) ........ | ... | ... | ... | ... | ... | ... | ... | ... | ... |
| Engine-room wages ........ | ... | ... | ... | ... | ... | ... | ... | ... | ... |
| Superintendence ........ | ... | ... | .. | ... | ... | ... | ... | ... | ... |
| Total cost of generating the energy | .. | ... | ... | ... | ... | ... | ... | ... | ... |
| Repairs and renewals of distributing plant ........ | ... | ... | ... | .. | ... | ... | ... | ... | ... |
| Wages outside generating station.. | ... | ... | ... | ... | ... | ... | ... | ... | ... |
| Superintendence do. do. | ... | ... | ... | ... | .. | ... | ... | ... | ... |
| Total cost of distribution ........ | ... | .. | ... | ... | ... | ... | ... | ... | ... |
| Total cost of producing and distributing the energy ........ | ... | ... | ... | ... | ... | ... | ... | ... | ... |

The columns B, C, D, correspond to similar columns in Table I., that is to say, the costs there recorded are to be annual, best and worst month respectively, in all cases to be from actual accounts, without deductions or allowances.

In order to bring repairs and renewal of plant to a common basis of calculation, it is requested that the annual sums to be divided into the units be taken at the following percentages on original cost of plant :—

Two and a-half per cent. on buildings, brickwork, and masonry.

Five per cent. on boilers, pipes, engines, dynamos, switchboards, and all cables or other conductors, covered with continuous insulation.

One per cent. on bare conductors, insulated by means of glass, porcelain, or other such like imperishable materials.

Fifteen per cent. on accumulators and transformers.

Superintendence.—The wages of same to be divided between costs of generating and distributing according to time occupied by each.

## SOUTH AUSTRALIA.

### POSTAL AND TELEGRAPH CONFERENCE HELD AT ADELAIDE, MAY, 1890.

The following is the text of the resolutions relating to Telegraph Service passed at the above conference, and signed by the Postmasters-General of New South Wales, Victoria, South Australia, Queensland,* and Tasmania.

1. That the following terms for reduction of cable rates, as proposed by the Eastern Extension Telegraph Company, be accepted, namely:—"Firstly, the tariff will be reduced to 4s. for ordinary messages, 3s. 6d. for Government messages, and 1s. 10d. for press messages during one year of trial. If at the end of the first year no very serious loss is involved, the experiment will be continued for two years more, and such extension must be at the option of the Company. If the loss should be nearly recovered at the end of the three years, the arrangement will be extended for the remainder of the subsidy. The whole proposal is conditional upon South Australia accepting 5d.—the transit rate." (Queensland dissented.)

2. "That in the event of South Australia reducing the telegraph rates on the trans-continental line, in accordance with any resolution agreed to by this Conference, the several colonies represented at this Conference, including South Australia, agree on the basis of population to guarantee to South Australia a revenue from the line equivalent to that received at present." (Queensland dissented.)

3. "That any colony or country not joining in the contribution to subsidy and guarantee, shall pay proportionately higher rates."

4. "That it be a recommendation to the various Governments represented at this Conference—1. That between any two contiguous colonies 1s. shall be the initial charge for twelve words, and 1½d. for each additional word; names and addresses to be paid for. 2. Between any three colonies 1s. 6d. to be the minimum charge for twelve words, and 2d. for each additional word. 3. Between Queensland and Western Australia 2s. to be the minimum charge for twelve words, and 3d. for every extra word. 4. Tasmania to be a minimum rate of 6d. for twelve words for each colony, plus the cable rates. Twelve words to be considered the minimum rate. Addresses and signatures to be paid for, and code addresses to be prohibited. 5. That the reduced rates come into operation on January 1st, 1891."

5. "That it is considered desirable to adopt a system of urgent telegrams, at double rates, locally and intercolonially."

6. "That the Uniform Intercolonial Telegraph Regulations, as drawn by heads of departments, be adopted."

7. "That in the opinion of this Conference it is very desirable that the heads of the Post and Telegraph Departments of the Australian colonies should frequently meet—annually, if possible—to consider and report to their respective Governments on all questions affecting the postal and telegraphic services generally."

8. "That the President forward to his Excellency the Governor of South Australia a copy of the resolutions agreed to by the Conference regarding the reduction of postal and cable rates to the United Kingdom, requesting that his Excellency will forward it to the British Government by cable, with the expression of the earnest desire of this Conference that, as England is equally interested with the colonies in securing and maintaining cheap telegraphic communication, the proposal of the Conference that Great Britain should contribute towards the subsidies and guarantees required may be accepted by the Imperial Government.

9. "That the President inform the Agent-General of South Australia of the acceptance by the Conference of the amended offer of the Eastern Extension Cable Company, and request him to confer with the Agents-General of the several colonies represented at this Conference in order that they may jointly urge upon the Imperial Government their acceptance of the proposal that England should contribute one-half of the subsidies and guarantees required in order to secure the reduced rates agreed to for telegraphic communication between England and the colonies of Australasia."

* Resolutions 4, 6, 7, 8, and 9 were passed after the Queensland Postmaster General had left the conference, and have not been assented to by him.

## THE CANADIAN GOVERNMENT TELEGRAPH AND SIGNAL SERVICE.

Under the direction of Sir Hector Langevin, Minister of Public Works, and the management of Mr. Gisborne, C.E., the Canadian Government have during the last decade gradually extended their telegraph and signal systems along their Atlantic, Gulf of St. Lawrence, and Pacific coast lines, submarine cables connecting the principal outlying islands dangerous to navigation. During the present season another cable has been laid from the west-end of the Island of Anticosti to Long Point, Mingan, some 600 miles below Quebec. When laying this cable one of the men in the tank stumbled, was caught by the cable, and instantly drawn through a 5½in. by 3ft. space between the top of the cone and the rigid 2in. iron ring known as the crinoline. The man's scalp was badly torn, chest crushed, two or three ribs and one leg broken, the cable snapping apart under the prompt application of the break. The poor man was promptly landed at Gaspe, and is now on the highroad to complete recovery. This parted cable having been duly recovered, and the laying successfully completed, the Government steamer "Newfield" then proceeded to Bird Rock, Magdalen Islands. This is a small island, 20 nautical miles distant from the group, having a superficial area of seven acres only, with overhanging cliffs from 110ft. to 140ft. in altitude, and upon which is a lighthouse and signalling station. The surrouding waters are shallow, viz., from two to three fathoms deep, with a flat rock bottom, covered with huge boulders, which move during heavy gales and when ice is running.

Notwithstanding every precaution, and the use of abnormally heavy shore end cables, eight seasons out of ten the line was out of order just at the time when reports as to the movements of the Gulf ice would have been of utility to passing shipping. The Government, therefore, decided upon abandoning the station in favour of one upon St. Paul's Island, at the entrance of the Gulf, between Cape Ray, Newfoundland, and Cape Breton, Nova Scotia, distant 20 nautical miles from West Cove station, on Cape Breton. The recovery, repairing, and relaying of the Bird Rock cable was entrusted to the skill of Captain Guildford, of the Government cable steamer "Newfield," and to Mr. Hartley Gisborne, son of the General Superintendent. Although over 10 years submerged, the deep-sea portion was recovered in half-a-dozen sections all in good condition, even the asphalte covering being intact wherever embedded in sand or mud, but entirely eaten away where it rested upon rock and seaweed. Some 16 miles of the recovered cable was thus available for the St. Paul's Island connection, which was duly completed, and is now operated by telephone. That the joints were skilfully made is best attested by the fact that "the Gaelic" spoken through the cable has not broken down the insulation! The "Newfield" next proceeded to the Bay of Fundy, where the Grand Manom Cable was repaired after being damaged by anchorage, and Cheney and White Head Islands of that group were connected with the Government system.

It now remains for the Canadian Government to connect that "graveyard" of the maritime world, Sable Island, with the mainland of Nova Scotia, only 100 miles distant from Halifax, to complete a service which has lately elicited the highest commendations from Sir George Baden-Powell, who is to report upon a similar telegraph and signal-service system for the British Isles at the next Session of the Imperial Parliament.

## PARIS NOTES.

(FROM OUR OWN CORRESPONDENT.)

PARIS, *November* 10, 1890.

The Préfecture de la Seine has just granted the Compagnie Parisienne d'Éclairage et de Chauffage par le Gaz a prolongation of its concession. The terms of this concession have now to be submitted to the Conseil Municipal for its approval. The Gas Company agrees to reduce the price of gas for lighting purposes from 30 to 25 centimes per cubic metre—that is to say, from 7s. 6d. to 6s. 3d. per thousand, and from 30 to 20 centimes in the case of gas engines, &c. The Company, moreover, engages to distribute one-half of its profits when they exceed 38,000,000fr. (£1,520,000) to the consumers. In return for this the Company is to have its concession prolonged from December 31, 1905, to the end of 1930, and it is authorised to exploit any system of lighting and heating whatsoever, including, of course, "*the electric light and other applications of electricity.*" The receipts of the Gas Company for the first nine months of the present year exhibit a falling off of nearly 3 per cent., compared with those of the corresponding period last year. The figures for August and September of this year are still more remarkable when compared with those for the same months of 1889, showing, as they do, a diminution of respectively nearly 8 and 6 per cent.

The sub-stations of the Popp Company have come into operation within the last few days. Each of the 33 sub-stations contains a large battery of Laurent-Cély accumulators. The sub-stations are divided into groups, the sub-stations in each group being connected in series with a dynamo situated in an eccentric station. The charging dynamos give 70 amperes at a pressure of 3,000 volts. The cables are highly insulated, and are run in rectangular cast-iron troughs. The batteries are divided into halves, so that one half can be connected to the charging main, while the other is connected to the supply mains. The feeders from each sub-station join a network common to the whole system. The Popp Company has, it will thus be seen, renounced the idea of building compressed air sub-stations, and carries out its distribution on purely electrical lines.

In consequence of the fire at the Grand Café, to which you referred in your last issue, the Conseil Municipal has decreed that

Digitized by Google

electric lighting is a dangerous industry, and have submitted it to the police supervision usual under such circumstances.

The contracts for the various works connected with the erection of the new Paris Central Telephone Exchange were awarded on Saturday. On the same day the official decrees relating to interurban telephonic conversation was published. A unit of conversation is fixed, and the price varies according to distance. With a view of fostering the growth of "réseaux téléphoniques secondaires" (suburban systems) the urban rentals in the case of towns of not more than 25,000 inhabitants have been reduced to 150fs. per annum.

At the meeting of the Société Internationale des Électriciens on Wednesday last week, M. G. Dumont read a long Paper on the "Applications of Electricity to Railways." He recalled the fact that it was Cook who, in England, first made use of the needle telegraph to facilitate the working of a railway. He next described the various systems of electric signals and the various block systems, automatic or otherwise, employed in the chief countries of the world. M. Gaston Roux showed an indicator by which one is able to read directly in per cent. from an equally-divided scale the exact state of charge of an accumulator. The action of the apparatus, it is needless to say, is based on the variation of the density of the electrolyte.

## CORRESPONDENCE.

### THE WESTMINSTER ELECTRIC SUPPLY CORPORATION.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: With reference to your kind notice of the work of this Corporation in last week's *Electrician*, will you let me supply one omission, viz., that the whole of the architectural work for the three stations, which has been very heavy and important, has been carried out by Mr. C. Stanley Peach, of 8, John-street, Adelphi.—Yours, &c., A. H. W. Kennedy.

Victoria Mansions, Victoria-street, S.W., Nov. 7, 1890.

### A NEW EMPIRICAL FORMULA FOR THE AIR-SPACE OF DYNAMOS.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: The following are the results of comparisons of a number of dynamos designed by me showing how the magnetic induction in dynamo-machines depends on the magnetising force:—

1. The total induction through the armature is proportional to the ratio of the magnetising force and the magnetic resistance (Kapp).

2. The magnetic resistance of iron of a given susceptibility is proportional to the ratio of length and cross-section of the path of induction (Kapp).

3. The resistance of air is proportional to the ratio of the length squared and the cross-section of the path (the Writer).

Hence, whilst the magnetic resistance between two parallel sides of a cube of iron is inversely proportional to the linear dimensions of the cube, *the resistance between two parallel sides of a cube of air is the same whatever be the dimensions of the cube.*

In dynamo-machines, with wrought-iron circuit, working at normal load, with 72,000 useful lines, C.-G.-S. per square inch in field magnet and 86,000 per square inch in armature core, if:—

$\beta$ = magnetic resistance of a cube of air.
$\gamma$ = " " " iron, the sides of which are 1in. long,
$m$ = total number of lines C.-G.-S. through armature,
F = magnetising force in ampère turns on field magnet,
Then I find:—

$$\beta = \cdot 0905$$
$$\gamma = \cdot 00294,$$

or, taking a kiloline (1,000 lines C.-G.-S.) as the unit of induction and denoting the total induction in kilolines by M:—

$$\beta = 90 \cdot 5$$
$$\gamma = 2 \cdot 94$$

$$\therefore M = \frac{F}{90 \cdot 5 \frac{\lambda^2}{\sigma} + 2 \cdot 94 \left( \frac{l_a}{s_a} + \frac{l_f}{s} \right)}$$

where $\lambda$, $l_a$, $l_f$ are the lengths and $\sigma$, $s_a$, $s_f$ the cross-sections of air space (total), armature, and field magnet core respectively, the unit of length in the last member under the line being 1in. $\gamma$ depends upon the susceptibility of the iron. With the densities used above, this is about the same in the charcoal discs in the armature as in the forgings of the magnets.

I hope to give figures proving my new theory in a short time.—Yours truly, F. V. Andersen.

November 10, 1890.

### LIFE OF GLOW LAMPS ON THE SERIES SYSTEM.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: In the discussion on Mr. Bernstein's Paper on the Series System, read in the Institution of Electrical Engineers in 1886, Mr. Mordey expressed the opinion that lamps on a circuit of constant current must of necessity be shorter lived than lamps on a parallel circuit; the reason being that the resistance of lamps rises in course of time. If placed in parallel, they will then take less current, give less light, but have a considerable preservative power.

This view appears very plausible, and it will, therefore, be of interest to many readers to hear that a Bernstein lamp, which was placed on a circuit of constant current of 10 amperes in Niagara-in-London, has been in use more than three years every night except Sundays, and has already lasted more than 10,000 hours. During the present year it has been run twelve hours daily.

The system on which this lamp has been run is known as the Woods system of arc lighting, and is owned by the Fort Wayne Electric Company of Indiana.—Yours, &c.,

Niagara-in-London. Frank Lott,
November 7, 1890. Electrical Engineer-in-Charge.

## TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning.*]

Tenders Invited.—Sealed tenders will be received by the Municipal Commissioner for the City of Bombay up to 1 p.m. on Monday, the 16th February next, for experimental lighting by electricity of certain streets of the City of Bombay for a period of two years. Forms of tender and schedule of conditions, and a sketch of the portion of the city, showing the streets to be lighted, may, on payment of £1 sterling, be obtained from Messrs. E. W. and R. Oliver, 1, Corbet-court, Gracechurch-street, London, E.C., who will on application give any further information that may be required. Further particulars are given in our advertisement columns.

The Lane Fox Electrical Company (Limited).—This Company have this week issued a notice cautioning Electric Light Supply Companies against the unauthorised use of the system of electric lighting covered by the Lane Fox Patents, with special reference to Nos. 3,988** and 4,626, both of 1878. A complete list of licensees is announced as nearly ready, and further particulars will be found in our advertisement pages.

*Re* Magnus Volk.—We are informed that Mr. Bramwell, who was appointed trustee of the estate of Mr. Volk, has been removed, and a meeting was held yesterday at Brighton to appoint his successor. It is expected that a second dividend will shortly be announced.

Lighting at the Guildhall.—On the occasion of the Lord Mayor's Banquet, at the Guildhall, on the evening of the 10th inst., the hall was illuminated by about 500 incandescent lamps, artistically attached to the gasoliers above the tables, and the excellent effect produced was greatly admired. The installation was carried out at very short notice by the Brush Electrical Engineering Company, in whose district the Guildhall is situated.

Messrs. Davey, Paxman, and Co.—Removal Notice.—This firm have removed their London offices to larger and more convenient premises, No. 78, Queen Victoria-street, E.C. Telegrams intended for the London office should be addressed "Paxman, London," and the firm's London telephone number is 1697.

Messrs. Taylor, Tunnicliff, and Co.—This firm, who are extensively engaged in the manufacture of porcelain fittings for the electric lighting trade, have recently completed special machinery for tapping with a very fine thread the small holes in porcelain switches, cut-outs, ceiling roses, &c., thus enabling manufacturers

Digitized by Google

to fit these articles up with metal work without the objectionable metal nuts, &c., at the back of the fittings. This will supply a want much felt by electricians engaged in fitting up these goods. The metal nuts have hitherto been a fruitful source of short circuiting.

Messrs. J. D. F. Andrews and Co.—This firm have purchased the goodwill and assets of the firm of Messrs. White, Romanze, and Co., Kingsbury-road, Dalston; and 3 and 4, Great Winchester-street, E.C., who have been carrying on the manufacture of arc lamps, switches, &c., and also telephones, type-printing instruments, and electric bells, besides electric light contracts. Messrs. Andrews and Co. intend continuing all the manufactures hitherto carried on by the late firm, but they are about to remove the machinery from Dalston at an early date to more commodious premises. Mr. Fred. White, of the above firm, who is well known in connection with electric light and telephone work, has assumed the position of manager with Messrs. J. D. F. Andrews and Co.

Messrs. Arthur B. Gill and Co.—This Company have just completed the necessary alterations to their large and convenient show-rooms and stores at 36, Parliament-street, Westminster, S.W., where they are showing and storing all kinds of electrical goods and manufactures. A large stock of Henley cables and wires will also be kept.

Herr J. Obermaier.—This firm has recently built near the town of Nürnberg a large new factory for the manufacture of electric light, telegraph, telephone, and power transmission wires and cables. The firm is an old established one, having been in existence in Nürnberg over 15 years; and we understand that the large extension of premises is owing to a very considerable increase of business.

The Jerome Kidder Manufacturing Company.—We have received this Company's catalogue, which contains illustrated particulars and prices of their electro-surgical appliances. Over 100 appliances are illustrated.

## PATENT RECORD.

### APPLICATIONS FOR PATENTS.

Note.—*The undermentioned applications are not open to public inspection until after the acceptance of the complete specification. The names within parentheses are those of communicators of inventions.*

October 27, 1890.

17,112. F. Bosshardt. Manchester. An automatic apparatus for the control of torpedo batteries (J. de Petroff, France).

October 28, 1890.

17,181. H. J. Allison. London. Improved electric switch (J. A. K. McGregor, H. Wallach, and S. J. Wallach, United States).

17,247. M. W. Dewey. London. Improvements in electric apparatus for transmitting motion.

17,266. J. C. Fell. London. Improvements in electric railways (C. Richter, United States).

October 29, 1890.

17,277. R. Wotherspoon, Glasgow. An improved method of and apparatus for the electrical treatment of sewage, wines, oils, air, gases, and other fluids (H. Rowley, Australia).

17,308. C. W. Cox and F. Robinson. Liverpool. Improved switch for electric light.

17,309. C. W. Cox, F. Robinson, and W. H. Gritton. Liverpool. An improved method of lighting ship's side, mast-head, and signal lamps by electric light.

17,322. E. Hartmann and W. Braun. London. Improvements in telephones.

17,327. H. W. Miller. London. An improved electric meter.

### SPECIFICATIONS PUBLISHED.

1889.

15,733. Ducretet. Electrical signalling apparatus. (Price 8d.)
16,237. De Ferranti. Electrical mains. (Price 8d.)
17,819. Slatter & Rixon. Electric switches. (Price 8d.)
17,915. Gisborne (Keeley). Telegraph circuits. (Price 8d.)
18,350. Davies. Dynamo-electric machines. (Price 8d.)
18,604. Perry and Others. Measuring, &c., electric currents. (Price 6d.)
18,755. Reckenzaun. Secondary batteries. (Price 6d.)
19,011. Hopkinson. Dynamo-electric machines. (Price 8d.)
19,081. Wreden. Micro-telephonic apparatus for drivers. (Price 8d.)
19,190. Lovell and Lloyd. Induction coils, &c. (Price 6d.)
19,554. Von Dolivo-Dobrowolski and Others. Alternating-current generators. (Price 11d.)
19,555. Von Dolivo-Dobrowolski and Others. Electrical induction transformers. (Price 8d.)

## COMPANIES' MEETINGS.

### Western and Brazilian Telegraph Company (Limited).

The twentieth ordinary general meeting of this Company was held at Winchester House, Old Broad-street, yesterday, Mr. W. S. Andrews in the chair.

The SECRETARY (Mr. R. M. Cunningham) read the notice convening the meeting, and the minutes of the last meeting, which were approved and signed by the Chairman as correct. The report of the Directors was taken as read.

The CHAIRMAN: The outcome of our last half-year's working as compared with that of the corresponding period of the previous year is an improvement in the gross receipts. That is always a satisfactory fact. It is not a large improvement, but it is in the right direction. In the corresponding half-year of 1889 your revenue amounted to £86,556, and in the past half-year to £89,846, showing an increase of £3,290. The increase really in traffic is larger than that, because the revenue in the corresponding period a year ago was increased by a profit on exchange amounting to £2,482. This half-year there has not alone been no profit by exchange, but there has been a loss, therefore that £3,290 does not represent the increase that we have had in message work, because we have had to do message work to make up the two items I speak of—the £2,682 and the £730. Turning to the expenditure, the total amount under abstracts A, B, and C for the corresponding period of last year was £32,772, while for the last half-year it was £33,342, or an increase of £569. In analysing the figures under abstract A, the amount was £16,885 in the June half of 1889, whereas for the past half-year the amount was £17,320, or a total increase of £434; increases being under five heads and decreases under ten, the upshot being the figure I named. I will go further into these items if you like, though I do not know that it will be worth while, as the total is only the sum mentioned. I shall be happy to do so if you wish it. The next we come to is abstract B. There again the difference in the total is extremely small, the increase being only £220. I will go into that if you like, or I will not further deal with it; it is hardly worth while. Then with reference to abstract C, which deals with the London expenses, I know that you always like to look at them a little narrowly, but if you do you will only find in the total a decrease of £86, made up of various little items. This leaves the total increase under all these heads £569. In the balance-sheet you find that we have set aside this year an increased sum of £1,000 for depreciation of ships. You find there has been less cable used to the extent of £800, and that again, as the outcome of all these figures, your increase in revenue is £3,290, while your increase in expenses is £569, your balance brought down amounting to £49,337, against, in the corresponding period of last year, £47,451. That, therefore, is an increase in the balance of £1,886, which is of course satisfactory. To the £49,337 must be added £3,248 brought forward and £7,385 received in dividends from the Platino Company, making £59,970. Then deducting £13,220 paid for Debenture interest, £7,500 for renewal fund, and £5,880 for Debenture redemption fund, there is £33,370 left. The Directors recommend you to delare a dividend at the rate of 4 per cent. per annum, and to carry forward £5,751 to the current half-year. If you agree to our resolution for the dividend, we propose to make it payable to-morrow. That I think disposes of the financial aspect of this period, and you see that there has been nothing very eventful. It has been quite an ordinary state of affairs. That, however, does not hold quite good with respect to what I may call the political aspect of the period compared with the political aspect at the present time. No doubt you will remember that when we met twelve months ago we were in rather a "parlous" condition. The Brazilian Government had absolutely refused to permit us to lay the new cables, the putting down of which you had approved, and of course in face of that prohibition it was quite impossible for us to proceed. In other respects, too, the position out in Brazil was extremely unsatisfactory. That is about as mild as I can put it. You will remember that on that occasion we went very fully into the questions between us and the Government. We read to you all the points of the concessions. We read to you the communications that had passed, and, in fact, I think we kept back no single item of any kind. Well, since that period, immediately after our meeting—within 24 hours of it, I think—there was a change of Government in Brazil, and instead of having to deal with an Empire we had to treat with a Republic. I am glad to say that our experience, as you will have gathered from the paragraph in the report with respect to loops, was more satisfactory with the Republican Government than with the Imperial. We first tried to do all we could to obtain the support of the British Government. Lord Salisbury met us in a very fair spirit. He inquired very fully into everything; the result of his inquiries was in our favour, and we obtained the moral support of our Government. I believe that that has done us much benefit, because the Government has, of course, no direct interest in the increase or decrease of dividends of a private Company like ours. This fact must have been pretty well appreciated by the Government of Brazil, and it has done a great deal for us. Our representative out there was exceedingly accurate, able, and prudent, conducting the negotiations in such a way as to earn the satisfaction of the Board. Of course, with a great Empire like Brazil, neither the Company nor any Government could bring pressure to bear. If we could not have convinced the Government we could have done nothing; but, fortunately, we succeeded in convincing them. We relied on the strength of our case, the weight of our evidence, and the sense of justice of the Government, and, fortunately, the latter has proved favourable to us. They have seen that any step of this kind must redound, as it has already redounded, to the credit of the Government in the financial centres of the

Digitized by Google

world, and that it must also benefit the commerce of the country. These loops, I am pleased to say, were eventually authorised to be made. I do not propose to go into any further detail with respect to our relations with the Brazilian Government, except to say that they are decidedly more satisfactory than they were; but I think in drawing attention to the activity, prudence, and discretion, I think I may say, of the Board. I ought, with the approval of my colleagues, to make special mention of the valuable services of Major Wood, Managing Director, and of the activity and energy of our worthy Secretary. In fact, we have been able to pull through, and I think we have benefited ourselves a great deal. Of course you are not to suppose that the laying of these cables will produce an increased revenue. That was not the object. The object is, of course, to enable us to fulfil our concessional obligations more effectually, and at the same time safeguard the line against interruptions. Of course, the effect of that is that we do not sustain loss of revenue by interruptions, and to that extent there is a financial gain. In the same way you will remember that under our agreement with the Brazilian Company we were to forfeit a sum of £5,000 a year. Of course, you will not have to forfeit that; and altogether the results of our laying the loops will be beneficial for our service, and will tend, I think, to ensure the position and stability of the Company. There is a special question before us to-day, namely, the purchase of the undertaking of the Montevidean and Brazilian Company. Our position at present, as most of you will remember, is this—we have an agreement with the Platino Company and the Montevidean Company. The Montevidean part of it goes to this, that it constitutes a second charge upon our gross revenue, because we have to give that Company a proportion of our gross receipts subject only to our A Debentures. That is, of course, an unsatisfactory thing, and we have been desirous of getting rid of it for some time. In addition to that, moreover, the same motive which involved our arrangement with the Platino Company, which was carried out a year or two ago, and which, I may say, has operated most satisfactorily, and proved a very advantageous arrangement in all respects, prevailed in this case, namely, consolidation of management. We do not want—you will all readily see the inconvenience of it—an administration interposed between us and the end of our line. We want to be perfectly free. We want to have full and complete control of this undertaking. Now, of course, in considering this we had, besides looking at it from the working point of view, to consider the financial point; and though we thought it advisable to acquire this thing, we only thought it advisable to acquire it at a price. The price works out in this way. That the amount we are now paying this Company from our gross revenue will pay upon the amount of shares which we give to this Company as the purchase price of their entire undertaking just 5 per cent. I do not think that that is a bad arrangement. Of course that Company does not pay 5 per cent., as it has to provide for Debenture redemption and ordinary expenses of management; but the capital will work out in this way: The Debenture and share capital combined of the Montevidean Company amounts to £96,640. For this we pay in our fully paid-up shares, taken at par value, £79,500, and, as I said, the purchase price upon that shows 5 per cent. We thus get rid of a charge coming in between the A and B Debentures, and we substitute for that charge a body of gentlemen—shareholders in the Company—who will be in precisely the same position as all of you. They will depend upon the profits for their dividend. They will be with you in prosperity, I hope, exclusively. The agreement will be read to you presently, and, therefore, I will not further describe it. I will now move the following resolution:—

*"That the report and accounts for the half-year ended June 30, 1890, now submitted, be and the same are hereby approved and adopted, and that a dividend of 6s. per share, being at the rate of 4 per cent. (free of income tax) be and is hereby declared payable on the 15th inst."*

Mr. C. W. EARLE seconded the motion.

The CHAIRMAN: The report has been moved and seconded, but before I put it to the meeting I shall be happy, if the shareholders wish to ask any questions, to reply to them to the best of my ability.

Mr. COPPIN congratulated the Board on the improved condition in which the Company appeared to be owing to the way in which the Directors had conducted the business in the past six months, especially in connection with the negotiations for laying the loop lines. If there was any feature at all that was regrettable, it was the increased expenditure. He had imagined from their improved income that they would have had a little better dividend on the present occasion than 4 per cent. Still, he presumed that the same care had been bestowed on the expenditure which had generally marked the working of the Board, and he hoped that in the future they would try, as far as possible, to keep down the very large expenditure which they had had to put up with in the last two or three half-years. It was, he said, scarcely fair to compare the expenditure of the past half-year with that of the corresponding period of the previous year, because in the June half of 1889 they had some extraordinary expenses. One of the ships was laid up for some time, and that accounted for an expense of some £7,000 or £8,000, the expenditure of the first half of 1889 being brought up to £39,104 against £32,000 in the same period of 1888. Between the June half of 1888 and the same period this year he found that their expenses had increased by £7,500, while their income had increased by only £3,000. It was very difficult for shareholders to put their fingers on the different items; but he hoped that the Directors would remember in all their transactions, while maintaining the efficiency of the cables, to keep as far as possible within necessary expenditure, especially abroad. It was there that the expenses occurred. The home office expenses did not appear to increase at all. With regard to the proposed agreement with the Montevidean Company, he would like to hear from the Chairman whether this line—it was only a small section, he believed, and it was necessary that they should have the control of it—would increase their dividend. They were going to pay a price for the undertaking of the other Company, which the Chairman had told them represented 5 per cent. calculated on the amount they were now paying to the other Company. That 5 per cent. would be a fixed charge.

The CHAIRMAN: No.

Mr. COPPIN: It was not a guarantee, but they would be paying this rate.

The CHAIRMAN: I think I have not made myself clear. We purchased that undertaking for ordinary shares in our Company. On the shares that we pay for the purchase of that undertaking the amount which we now have to pay them from our gross receipts shows exactly 5 per cent. There is no fixed charge of any kind.

Mr. COPPIN said he understood this; but the amount this Company would have to pay for the right of running over the Montevidean Company's line would represent a dividend of 5 per cent. on the shares which they would give to that company. Then if the expenses of working the Montevidean line were in the same proportion as the expenses of working the other portion of the line, between 40 and 50 per cent.——

The CHAIRMAN: They will be *nil*. There will be no working expenses in respect of that.

Mr. COPPIN said that that cleared the point. He had been only anxious to know whether, in taking over this line, they were going to increase their expenses. This was all that he had to say, and he thought that, on the whole, the Directors and the shareholders were to be congratulated on the very improved condition of the affairs of the Company.

The CHAIRMAN: There are one or two observations which Mr. Coppin has very properly made which would have been dealt with by me but for the desire I felt not to take up too much of your time. I did mention the exchange as a thing that we had to earn by increased labour, which cost no labour at all when it was in our favour. But there is something else, which, no doubt, you will remember, for it is a fact which is far more important and grave in its incidence than the question of exchange, and that is the reduction of tariff. You will remember that some time back we made a very large reduction in the tariff. I have been extremely surprised to see the way in which it has recouped itself, owing to the peculiar state of things which has been prevailing in the Argentine Confederation and Brazil. We are actually earning more money with a considerably reduced tariff; but that involves something. It involves more work; and if I had gone on to explain these items, I should have told you that in addition to that difference in the exchange, and of gain and loss in exchange, we have had to make up the sum lost by the reduction in the tariff and the transmission of increased work; and what do you think that that work amounts to? To 26 per cent. An increase of 26 per cent. in the work of the Company, I need scarcely tell you, cannot be done for nothing. We have had to extend our hours of work; to apply a duplex in one part of our system where there was a bit of congestion, and that means double staff, double work, and double hours. We have had to open a new station at Chuy, and to do several other things. I think that shows pretty clearly that we have kept an eye on our expenses; and as to this general sheet respecting foreign expenses, Mr. Coppin says we spend our money abroad; but it is there where, I would equally observe, we earn our money, and therefore that is where we must spend it. With respect, however, to this matter, there were, as I have said already, five items in which there were increases of expenditure, and ten items in which there were decreases. That, I think, shows that where we can arrive at a decrease we do so. With respect to the ships, there, again, two or three things come in. The "Buccaneer," in the corresponding half of the previous year, was responsible for £3,200. You will remember that the "Buccaneer" was in commission instead of the "Norseman." The reason why there is a large increase in the expenses of the "Norseman" this year is that there has been no "Buccaneer," the "Norseman" having been at work the whole six months; and mark this, which is an important fact as showing the way in which we put our finger down upon expenses, that the great increase there has been in coal, which was £1,500 more. We did try—I daresay the shareholders may remember it—to send out coal on our own account, but the effect was that when we wanted coal anywhere else we could not get it. They said, "If you are coming out with your coal, we will 'salt' you when you have not any." We therefore had to pay the local price of the coal, which, as I said, has cost us this half-year £1,500 more. If it had not been for this increase of £1,500, there would have been a reduction instead of an increase in ships' expenses. Well, gentlemen, the report has been moved and seconded, and I will now put it. Having submitted the motion in the usual way, he declared it carried. Continuing, he moved the following resolution:—

*"That the agreement, dated November 3, 1890, between the Montevidean and Brazilian Telegraph Company and this Company for the acquisition by this Company of the undertaking of the said Montevidean Company be and the same is hereby approved and confirmed, and that the Board are authorised to carry the same into effect."*

The MANAGING DIRECTOR (Major Wood) seconded the motion.

Mr. BOMPAS afterwards read the proposed agreement between the two Companies. It stated that the shares which were to be issued to the Montevidean Company in payment for their undertaking were not to rank for dividend until after January 1st next.

Mr. COPPIN inquired whether the Directors had any information as to the condition of the line. Was it in fair condition?

The CHAIRMAN: We have to maintain it ourselves; we maintain it and work it. It is in excellent condition. He then put the motion, and having declared it carried, stated that there was no other business before the meeting, and he thanked them for their attendance.

A SHAREHOLDER proposed a cordial vote of thanks to the Chairman and Directors for the way in which the affairs of the Company had been managed and explained to them.

The motion was seconded, and carried unanimously.

The CHAIRMAN: I thank you very sincerely for the hearty way in which you have been good enough to receive and pass this vote.

The proceedings then terminated.

## The West India and Panama Telegraph Company (Limited).

The twenty-seventh ordinary general meeting of the members of the West India and Panama Telegraph Company, Limited (incorporated January 9. 1877), was held in Room 47, Winchester House, 50, Old Broad-street, on Wednesday, November 12th, to receive the report of the Directors and the accounts for the six months ended June 30, 1890, to declare dividends and to transact other businsss of the Company. Mr. C. W. Earle presided.

Mr. R. T. BROWN (the Secretary) read the notice calling the meeting and the minutes of the last meeting, which were confirmed and signed as a correct record.

The report of the Directors was taken as read.

The CHAIRMAN, in moving the adoption of the report and statement of account to June 30th, said that it was the most satisfactory one that the Directors had laid before the shareholders of the Company. However, at the best it could not be called a good account, and so long as the condition of the field in which they worked remained as it was now, he regretted to say that he did not see the possibility of their position becoming very brilliant. But still at the same time there were features that could only be regarded as satisfactory. The traffic receipts were slightly larger than they had been before, and the working expenses, outside the head of repairing expenses, were rather less than the average, and the net result of the half-year's operations was to give them the best outcome of any half-year that the Company had ever had. The cost of repairs of cables was rather in excess of the average; but that was a matter that compensated itself, because the more cable the Company were obliged to put into the system in repairs and renewals, the less they had to contribute in sovereigns to the reserve fund, which was calculated on the amount of depreciation that was supposed to be going on in the cables. He was glad to be able to say that he thought that they were now within reasonable distance of getting rid of the incubus that had weighed upon them for so long a period in the shape of arrears of interest on the Second Preference shares. The sum that they still owed on the Second Preference capital was £1. 8s. 6d. per share, amounting to a total of £6,653. He would like to call their attention to the fact that in the year 1884 the sum that they owed to the Preference shareholders was £65,000. He thought that under the circumstances the shareholders would be willing to admit that good progress had been made, considering the poor traffics that the Company had been in receipt of. As regards the Barbadoes and Demerara cables, the report informed the shareholders that they had settled the terms on which they would lay the new cables and the Barbadoes cable was laid, and they were now in progress of negotiation for a similar cable for duplicating the existing system between Demerara and Trinidad. They had felt it a wise policy to carry out the work for the duplicate connection of these two colonies; but at the same time, he wished to point out that the increased outlay was not to open up any new traffic, as it was simply a duplication of cables which were already in existence, but still there was the probability that they would save something in the course of the year by preventing the communication being interrupted, and the consequent loss of traffic and also loss of subsidy. The position as regarded Demerara would, he believed, be almost immediately settled. The Directors had had a telegram yesterday saying that certain features in the proposed Act to which they made objection had been removed, and they would probably in a short time receive the text of that Act, and then, if they were perfectly satisfied, they would proceed with the laying of the 300 miles of cable between Trinidad and Demerara. In order to replace the cable used out of stock in laying the St. Vincent and Barbadoes cable, they had brought the ship "Grappler" home, and she was now in the Thames repairing and being thoroughly overhauled preparatory to taking in the cable which was ready for her at Messrs. Siemens Bros. and Co.'s works. The alterations and repairs to the ship now being carried out would render her valuable to the Company, and efficient for a long period to come. Referring to the recent Telegraph Conference at Paris, he stated that it was attended by himself, accompanied by Mr. Brown (the Secretary), on behalf of the West India and Panama Company. They were in Paris for a month, and they had several interviews with the Spanish authorities and with the French authorities as to the position of their relations in the West Indies, and he thought that in many instances the result of their attending that Conference would be found to be beneficial to the Company. While himself and Mr. Brown were in Paris they were fortunate in being able to obtain the assistance and the advice of Sir James Anderson, Mr. Andrews, and Mr. Ford (Directors of the Company), who happened to be in Paris at the time representing other telegraphic companies. With reference to the traffic receipts of this Company for the current half-year, they were certainly good, and he really began to have the hope that better things were coming for this Company as well as for the West Indies. Still, at the same time, he must not neglect to caution the shareholders against running away with the idea, because there were improved prospects before the Company, that they were going to step at once into a perfect El Dorado in the West Indies. It was one of the poorest fields that he knew of for telegraphic services. The receipts per mile were only half the average of those of other trans-oceanic cable companies. He, therefore, begged the shareholders not to expect that they were going to jump into dividends at once, because they were told at the last meeting they had shortly to face the likelihood of the loss of the Martinique subsidy, and in five years' time the Guadeloupe subsidy would expire. Therefore, again, he deprecated in the strongest terms any exaggerated idea as to the prosperity that the Company was likely to get which might run up the shares to a price that would be bound ultimately to disappoint those new shareholders who might come in at the high price. He did not know that he had anything further to add. He would be happy to reply to any questions that any shareholder desired to ask, and he begged to move:—

"*That the Directors' report and accounts to June 30, 1890, submitted to this meeting be, and the same are hereby, received and adopted, and that, as recommended by the Board, a payment of 6s. per share on the First Preference shares (being dividend for the six months ended June 30, 1890), and £3 per share on account of arrears of dividend on the Second Preference shares be, and the same is hereby, declared.*"

Mr. FORD seconded the motion.

Mr. LUCK: After the somewhat depressing address of the Chairman, I hardly like to ask the question as to whether he thinks there is any likelihood that next half-year the ordinary shareholders—the 88,321 ordinary shares—will receive a dividend?

Mr. GRIFFITH characterised the report as certainly one of the most satisfactory that had been presented to the shareholders of that Company. He was glad that the careful management of the Directors had proved successful in piloting the Company through the troubled sea into somewhat quieter waters for the future. The report had been so clearly explained by the Chairman, and was also so explicit itself, that it hardly called for any further remark, but there was just one point upon which he would like to offer an observation, and that was the smallness of the amount of interest that they got upon their investments. They certainly did very wisely in keeping a good reserve fund invested in sound securities, but he must say that the sum of £3,177 interest on those investments was very small. If they had gone in for the "despised Goschens" they would, he thought, have got a little more, and at the same time, although these investments were very sound and good, a little more security.

Mr. SAUNDERS said that he would like to remark that his opinion coincided with that of the gentleman who had last spoken, that they ought to get more for the money that was invested, and formed the reserve fund. He made out that they only got about 2¼ per cent. return interest on the money.

The CHAIRMAN: £3. 16s. per cent. is the average interest on the investments.

Mr. SAUNDERS: I do not make it out that.

The CHAIRMAN: The figures in the accounts are for the half-year.

Mr. SAUNDERS: Oh, yes! of course.

The CHAIRMAN, in reply to the various other remarks, said that as to the first question as to what prospect there was for the payment next year of a dividend on the ordinary shares, that was a problem that he would prefer for the shareholders to solve for themselves. He had told them that the arrears of interest on the Second Preference shares was now only between £6,000 and £7,000, then they had to pay the interest on the First Preference shares, and in addition they had to provide what was necessary for the expense of repairs, renewals, &c., in the half-year, and they would then find out if they had any sum still available for the payment of dividend on the ordinary shares.

Mr. FORD remarked that it had to be borne in mind that before they could pay anything to the ordinary shareholders they had to find the money for the payment of the then current half-year's dividend on Second Preference shares also.

Mr. LUCK said that he hoped that they might expect that there was a possibility of a payment to the ordinary shareholders at the next meeting.

Mr. FORD said that the answer would be easier to give if the shareholders could tell the Directors what amount they would be put to for repairs and renewals. That was the element of uncertainty that had to be faced in any calculation as an important factor.

The CHAIRMAN said that of course the possibility of the ordinary shareholders getting a return was far greater now that the arrears of interest on the Second Preference shares had been virtually wiped off. As to the question of interest, that he thought had been already explained. He did not consider that £3,000 odd for the half-year could be regarded as bad, looking at the high-class securities that they held.

The resolution was then put to the meeting and unanimously carried.

The CHAIRMAN stated that that was the whole business of the day, and it only remained for him to thank the shareholders for their attendance.

Mr. GRIFFITH moved a very hearty vote of thanks to the Chairman and Directors of the Company for their past services through trying and difficult times. He remarked that they were much indebted to them for the manner in which they had wiped off the arrears, and he expressed the hope that they would carry on equally good management in the future, now that brighter days seemed dawning for the Company. He thought they deserved a hearty vote of encouragement.

Mr. FISON seconded.

The motion was carried.

The CHAIRMAN, on behalf of himself and colleagues, briefly responded, and promised a continuance of their efforts in the Company's interest.

The meeting then separated.

## The Metropolitan Electric Supply Company (Limited).

The third ordinary general meeting of this Company was held on Friday, November 7th, at Winchester House, Old Broad-street, under the presidency of Sir John Pender, K.C.M.G.

The SECRETARY (Mr. E. Cunliffe Owen) read the notice convening the meeting, and the report of the Directors was taken as read.

The CHAIRMAN then said:—The report will have explained to you our reasons for calling you together to-day. Under the Electric Lighting Act it is provided that companies with statutory powers must present their yearly accounts, made up to December 31st, to the Board of Trade not later than March 25th in the year following. You will remember that our Company was formed in the autumn of 1888, and we naturally made up our first year's accounts to September 30, 1889, and our general meeting was held to confirm these accounts in December last. The Board of Trade

Digitized by Google

having intimated that they expected us in future to comply with the statutory requirements above referred to, we have found it necessary to alter the period of our financial year, which will therefore end in future on the last day of December. We shall, therefore, call you together again in the spring, for the purpose of submitting to you our accounts, and our meetings will henceforth be held in the beginning instead of at the end of the year. I am very glad indeed to meet you today, for I am anxious to place before you such information as will enable you to share with the Directors the confidence which they feel with regard to the position and prospects of the Company. It has always been my policy as Chairman of other companies that the greater we could strengthen the confidence between the shareholders and Directors the more smooth would our proceedings be, and the more satisfactorily would the business be conducted. When we last had the pleasure of meeting you I stated that we were supplying current for 15,000 lights to 58 customers. We are now supplying current for 40,000 lights to 300 customers. You will observe the great increase in the lights and the increase in the number of our customers, but you can well conceive what an enormous number of customers we have yet left to supply. It is one of the great features of our prospects at the present moment that we have such a wide field before us, and I hope I shall be able to satisfy you before I sit down that that field we are likely to occupy with considerable benefit to all concerned. I may state that this number of lights is largely in excess of that supplied by any other company in the United Kingdom, and that it is equal to about one-third of the total number supplied in London by public companies. I am informed by our manager that we hold contracts for a further 10,000 lights, and that there are many more applicants who are negotiating with us for the supply; indeed, I may say that it has been our experience that the number of applications grows steadily with and in proportion to our number of customers. I have in my hand a table, showing the monthly increase of our lighting during the present year, which will give you some idea of the steady and assured growth of our business. I will also read to you a few testimonials which we have received expressing entire satisfaction at the supply which we give. That is a further important point. I daresay you have all heard of complaints about the electric light—that it has been uncertain, irregular, and so forth. We have had nothing but complimentary letters from our varied customers, which give, after all, the best assurance of their number being rapidly increased. The testimonials it is well that I should read, because they are important. This is from Mr. Augustus Harris, of Drury Lane Theatre:—

Theatre Royal, Drury Lane, April 21, 1890.

My Dear Sir,—I have no hesitation in affirming that the Electric Light supplied by your Company, "The Metropolitan," is, and has been, in every way satisfactory, both as to quality and regularity.—Yours faithfully, Augustus Harris.

E. S. Claremont, Esq.

From George Edwardes, Esq., Gaiety Theatre.

Gaiety Theatre, Strand, April 21, 1890.

Gentlemen,—In reply to your inquiry, the light you have been supplying is extremely satisfactory. There is not the slightest fault to find with it, the current being regular and the light brilliant.—Yours truly,

Geo. Edwardes.

The Metropolitan Electric Supply Company (Limited).

From E. Kennedy, Esq., Exeter Hall.

Exeter Hall, Strand, May 9, 1890.

Dear Sir,—I am pleased to inform you that the installation of the electric light at the Central Young Men's Christian Association has proved a complete success. We are very pleased both with the continuity and the quality of your supply, and I shall be at all times pleased to afford any persons bearing your card an opportunity of viewing the light.

I am, dear Sir, urs faithfully,

(Signed) E. Kennedy, General Secretary.

E. S. Claremont, Esq.

From C. G. Compton, Esq., Garrick Theatre.

Garrick Theatre, April 21, 1890.

Dear Sir,—I beg to state that the lighting of this Theatre is in every way satisfactory, both as to purity and regularity.—Yours faithfully,

C. G. Compton.

To the Manager of the Metropolitan Electric Supply Company (Limited).

From Messrs. Hampton and Sons, Pall Mall East.

Pall Mall East, April 19, 1890.

Dear Sir,—We have much pleasure in stating that the lighting of our premises upon the Low-tension System is most satisfactory, the whole 640 lamps giving a good steady light. We heartily congratulate you upon its success.—We are, dear Sir, yours faithfully, Hampton and Sons.

E. S. Claremont, Esq., The Metropolitan Electric Supply Company.

And I am just reminded by one of our Directors, a great personal friend of Mr. Hare, that that gentleman has given us a testimonial. Mr. Hare's statement is this: "I feel when I leave the theatre at night quite a different man from what I used to be when we had the gas. I find that I am now in a pure atmosphere, and I can do my work better." You see, gentlemen, that even from a sanitary point of view electricity is immensely beneficial. I have not given you private testimonials, but the testimonials which we have received from theatres and large establishments, where it is so important that the light should not only be steady but pure; and I think this evidence of what we are doing is a very striking indication of what we may expect in the future. I am now going to show you the increase of our lights. The total number of lights supplied on March 1st was 16,702; April 1st, 19,134; May 1st, 21,388; June 1st, 22,991; July 1st, 28,595; August 1st, 30,711; September 1st, 33,642; October 1st, 35,209; and on November 6th, 40,033. You will observe that we have passed through the summer with a very fair average. We have been rising up to a point which is very considerable, and before I see you next spring, I expect to see at least 10,000 more lights added. All this, I am sure you will agree with me, is satisfactory as to the progress of the Company. A glance at the maps which we have prepared will show you the magnitude of our operations. You will notice the supply stations—Whitehall, Sardinia-street, Rathbone-place, and Manchester-square—together with the vast system of underground mains that has been carried out. Upwards of forty miles of mains have been already laid, and we roughly estimate that to complete our system at least double this quantity will be required. That will give you some idea of the work that has to be done, and the time that is required to do it. The following statistics on the subject of our areas may be of interest as showing their magnitude and importance:—Acreage, 3,105; houses, 45,451; rateable value, £4,500,000. The report states that we have obtained powers over Paddington. This district adjoins our other areas, and, therefore, will form part of our general system. We have obtained an advantageous site on the canal bank, and are about to commence active works; and while the Paddington station is being constructed, we shall be able to supply from Manchester-square as much lighting as we can lay the mains for in the Paddington district. I may here observe that we have no intention of applying for further districts at the present time. We do not consider that we should be justified with our present issue of capital in incurring further responsibility and liability. We are satisfied that our present areas are amply sufficient both in size and importance to take up all our energies at the present moment, and we believe that it is conducive to the interests equally of shareholders and consumers that we should develop the resources we have already acquired. Now our capital at the present moment is £500,000. When I was examined before the Board of Trade Inspector who was appointed to inquire into the general electric lighting of London I stated that I should not be satisfied as Chairman of this Company until our capital became at least two millions sterling. I hold precisely the same opinion to-day. I believe that it will be so successful and so remunerative that we shall gradually extend our system until we have got at least a couple of millions of money invested in it. I will now describe to you in as few words as possible the present condition of our supply stations. Our Whitehall station has caused us a certain amount of disappointment, owing to the fact that the large block of buildings called Whitehall Court, which it was originally constructed to light, and which we were under contract to supply, has not been occupied quite so speedily as we might have wished. There has therefore been some delay in the Whitehall station being as productive as at one time we expected it would be. We thought it would be immediately productive; but I am glad to say that these chambers are now beginning to attract considerable attention, and probably before I meet you again I shall be able to report that a considerable number of them are being lighted from the Whitehall station. We are also negotiating for the supply of current to other buildings in the neighbourhood. I may mention that this station has 710 horse power. It is supplying 4,177 lights, and it is capable of supplying 8,000 lights. The next station is Sardinia-street. We have every reason to be most satisfied with the working of this very important station. I informed you at our last meeting that we had given an order to double its capacity. This contract has been carried out, the machinery is now in working order, and we are ready to cope with any demand on it that may arise. We have at this moment 19,500 lights running from this station, and I may state that we have here a plant of 3,000 horse-power equal to supplying 50,000 lights. The demand is increasing, and now that we are in the winter it is increasing at rather a rapid rate, so much so that lately we have not been canvassing, but are only taking up the work that is brought to us, and there are a great many applications for extending the light. The next station which I shall refer to is Rathbone-place. I have already informed you of the circumstances which led us to purchase and develop the small station which has existed for some time on this site. The new machinery which we ordered some time ago is now fast approaching completion. Indeed, it would have been finished before now had it not been for many serious difficulties which have now, I am glad to say, been successfully overcome. These difficulties were of a mixed character. In the first place, I daresay you know that if a man has got a house alongside any electric installation, his belief is that he ought to make some claim against the Company. We have had injunctions threatened without number, but all of them in Rathbone-place have been overcome. The other day our landlord of Rathbone-place died, and his property was brought to the hammer. I went to the sale after consulting the Directors, and we bought his interest in the property. The advantage of purchasing this site is that it gives us control over the property. In the second place, it gives us something like 8 or 9, probably 10 per cent. We shall be able to get the money for a great deal less, so that at the end of 21 years, instead of, as according to our late lease, requiring to pay double rent, we shall be able at the end of that time to stand without any rent at all. I think that that must be satisfactory to the shareholders for another reason—that it has given you a tangible security; and not only is it a security, but it has enabled you to work the station at a much lower expense. At Rathbone-place station the horse-power is 1,200, and the total capacity in lights when finished will be 21,000. The next station is Manchester-square. To this station we attach the very greatest importance. It is situated in the midst of the wealthy parish of Marylebone, and promises to be one of the most lucrative stations in our districts. You may remember that at the last meeting I informed you we had made advantageous terms with the London Electric Supply Corporation, by which we took over from them their existing network of mains in the Marylebone district. We were thus enabled to supply from this station the whole of the then existing demand as soon as our machinery was ready to run. By this means,

Digitized by Google

although the machinery has only been at work for a period of four months, we are now supplying 11,000 lights. The total capacity of this station will be 35,000 lights, its horse power being 2,000. You will remember that the Directors have always laid very great stress upon the communication by trunk mains between one station and another. By this means we shall always be able to cope with any sudden demand in any one of our districts, and should any accident arise, the load of one station could at once be transferred to another station. One great point that we originally insisted on was that we were not going to be speculative, that we would let others experiment, and that we should reap the result of their experiments. At the present moment, though we have all these different installations, we can unite them together and make one powerful combination at any moment. That is a very important feature in this Company's business. The laying of our mains has taken a considerable time to effect, and I am sure you will realise that we have had to encounter many difficulties in the course of our works. Anyone walking about the streets of London will see constantly interruptions to the traffic owing to these works, and you can well conceive the difficulties we have in those neighbourhoods where we have to interfere with the traffic. Shopkeepers complain—everyone complains—and it is not a pleasant task to keep things quite smooth. But still, we have been able to keep on fair terms with everybody, and we are pursuing our work steadily and successfully. I may state that the whole of these works are being executed by our own men under the superintendence of our engineering staff, and I need scarcely say that this is a far more economical method than that of employing contractors. These works have necessarily brought us into frequent contact with the Local Authorities and with the County Council, and I should like to take this opportunity of expressing publicly our appreciation of the kindness and courtesy now shown to us by the officials of these bodies. Turning to our financial position, I would remind you that owing to the circumstances under which we have called you together we have no audited statement to submit; we have, however, gone very carefully into the matter, and I have no doubt that it will be satisfactory for you to hear that even with the necessarily small amount of our revenue at the close of last year and the commencement of this, we have every reason to believe that we have more than paid our way, and that we have made a small profit in the short time that we have been at work, and that profit I may say has been made upon something like 30,000 lights. We are very pleased to be able to make this statement for the following reason, which we are anxious that you should carefully bear in mind. Our working expenses in the past, and even at present, are with few exceptions the same to all intents and purposes as they will be when we are giving our present maximum supply of 114,000 lights. That is a very important point—that the staff employed in the production of 40,000 lights is far larger in proportion than that which will be required to conduct our full out-turn of 114,000 lights. When I state to you that we have made a small profit on the out-turn of 30,000 lights, it does not require a great amount of imagination to see that it must be a very good business if we can conduct 114,000 lights with a comparatively small increase in working expenses. Of course there will be an increased consumption of coal. Incidentally to that I may mention that in consulting our experts, it is calculated that, not including the current expenses of general management, but the cost of coal and of working the machinery, we shall be able to produce electricity at the central station for about 3½d. per unit, as far as we can now see. That is the most satisfactory point, I think, yet ascertained in regard to the experience of working the electric light. If we can prove, as I hope, when I see you three or four months hence, when we shall have had three months' winter's lighting, that all that I have said now is borne out, I think I shall be able to congratulate you on having made an investment in a very sound and prosperous concern. As you know, we get 7½d. per unit, and there is a very considerable margin between 3½d. and 7½d. to allow for our other expenses. You may naturally ask, why should we spend so much at the present time upon the staff? Well, ours is a new business. We have thought it advisable to afford an opportunity to our engineering staff to gain the experience necessary to cope with this business by appointing one of sufficient size when the business is small, and thus giving it the means of becoming familiarised with the special requirements of our systems by the time that we are working at a maximum capacity. With the present large growth of business over what it was six months ago, and with an assurance of a continuous and steady increase from the present time, we believe that we are perfectly justified in stating as we do in the Report that we look forward to a satisfactory dividend being earned during the ensuing year. I have heard some people say that a dividend might have been expected during the present year; I think this is a little unreasonable, inasmuch as the Company has only been founded for little more than two years, and has only been in possession of its Parliamentary powers for little more than one year. During this time the works which I have endeavoured to describe to you have had to be executed, and already we are able to announce that with an average output during the present year of, say, 25,000 lights, and with our working expenses, as I have already endeavoured to show you, almost as heavy as they will ever be, we have run at a small profit. It does not, therefore, take much power of calculation to see, as I have said, that there is a very fine field before us. I do not think I have omitted anything that I ought to have said. I may mention that at the different stations we have 6,710 horse-power capable of supplying 114,000 lights. I may state that if 30,000 lights give us a small profit, the difference between 30,000 and 114,000—that is to say, if the increase is conducted with only the additional cost of coal—will give, as you may calculate for yourselves, a very considerable income out of the large additional number of lights. I do not like to promise or to prophecy much; but when I stated to you just now that this undertaking must grow to be a very large one, I speak now with a great deal more confidence than I could have done in its earlier days. We have many gentlemen round this table, but one of our number is absent on account of ill-health—Sir Geo. Elliott. He entirely concurs in the views which I have expressed to you. When I look back to our first days I think we did a little bit of prophecy too, but I must say that all our prophecies were realised, and I believe that the statements I have made to-day will be realised in the future of the Metropolitan Electric Supply Company. With these remarks I beg to thank you for being present, and to move—

"*That the report of the Directors submitted to this meeting be and is hereby received and adopted.*"

If any gentleman wishes to put any questions to me I shall be only too happy to answer them to the best of my ability before putting the motion.

Alderman Sir ROBERT N. FOWLER, Bart., M.P.: I beg to second the motion, and I need not add anything to what the Chairman has said.

A SHAREHOLDER asked whether the 30,000 lights and £30,000 were the same thing.

The CHAIRMAN: Not necessarily. We are selling our electricity now by meters, and therefore we must have a year's experience to see how the consumption works out before we can give any definite answer.

Another SHAREHOLDER wished to know whether the Fleet-street newspaper offices were lighted by these lights, because this seemed to be rather important.

The CHAIRMAN said that these offices were not in the Company's district. Fleet-street was in the City.

The SHAREHOLDER failed to see that the City had done anything in connection with the lighting.

The CHAIRMAN said that the City authorities seemed to know, or thought they did, a great deal more than other people about what the lighting could be done for. It was a sort of rule and thumb with them. They thought that it ought to be done for so much, and the Company were not prepared to enter into a bargain with them.

A SHAREHOLDER asked whether they were making arrangements to supply motive power as well as light.

The CHAIRMAN said that the demand for light, which was their primary object, was such at the present time that until this demand was satisfied they had no time to turn their attention to the supply of motive power.

Mr. GILES, M.P., understood the Chairman to say that they were increasing their district by adding Paddington to it, and that they were already supplying over 40,000 lights, which was more than any other company supplied. Did that mean that they were more forward in the completion of their work than other companies, or that other companies had not districts which would require such a large supply? The Chairman had also said that their capital was £500,000, and that he would not be satisfied until it was two millions. Did this mean that they were going to issue new shares fairly soon?

The CHAIRMAN replied that the capital was £500,000, and that they had certain installations now, but they would not put down new ones until he could satisfy them that those they were now working were paying a handsome profit. The moment they could prove that their system was a success mechanically, electrically, and financially, he would call on the shareholders, and he expected they would be glad to join with them in pushing ahead and adding another half-million to the capital. They would not do it all at once.

Mr. GILES had, he said, asked a question at the last meeting with regard to their progress and that of other companies.

The CHAIRMAN: It is not for me to criticise what other companies are doing. I said when I first addressed you that we were not a speculative Company—that we should take the best system that existed and that we should take advantage of any improvements that came out. I think I may say, perhaps, that we have managed our capital more prudently than other people, and that we have got more for it than they have. As to Waterloo Wharf, we are at present utilising that station as a store. It is on the Thames, and it is very useful in every way for that purpose. But we have a plant in existence that we intended to put down there. There is a good field there, but we are not going to occupy it until we satisfy that the field we have occupied is productive. I think I have answered you pretty fully, and I have, I think, satisfied you, although some people have been complaining that they have been getting no dividend. While we were spending money to create all these installations which are now beginning to bear fruit it was not possible for us to pay you a dividend. The same can be said of a cotton mill, or of a steamer, as Mr. Giles will know. You cannot begin to pay a dividend on a steamer until it is floated and earning money; so it is with us. Our installations are now nearly completed, and are earning money, and our lights are being taken up very rapidly. When I meet you again I believe I shall be able to announce something satisfactory to you in the way of dividend.

He then put the resolution, which was carried unanimously.

Mr. GILES proposed the re-election as Directors of Sir James Anderson, Mr. J. Spencer Balfour, M.P., and Sir George Elliott, Bart., M.P.

A SHAREHOLDER seconded the resolution, which was agreed to *nem. con.*

Messrs. Deloitte, Dever, Griffiths and Co. were afterwards appointed auditors for the ensuing year.

The CHAIRMAN wished to say, before separating, that nothing would please the Directors more than that the shareholders should visit the various installations and see what had been accomplished by the Company.

A vote of thanks was then passed to the Chairman and Directors, and

The CHAIRMAN, in acknowledging the compliment, said that the greater the confidence between the Board and the shareholders the more prosperous their business would become, and he hoped that this was the beginning of meetings at which they would always have occasion to congratulate one another.

The proceedings then terminated.

## NEW COMPANIES REGISTERED.

**ELECTRICAL SUPPLIES AND FITTINGS COMPANY (LIMITED).**—Registered by Wilson, Bristows and Carpmael, 1, Copthall-buildings, E.C., with a capital of £20,000 in £5 shares. Object, to carry on the business of electricians and mechanical engineers. The first subscribers are:—G. L. A. Rooke, J. A. Roxburgh, J. Whitehead, T. B. Arundell, W. L. Madgen, N. G. Bingham, and G. S. Butler. There shall not be less than three nor more than nine directors. The first to be appointed by the subscribers to the memorandum of association. Qualification, £200. Remuneration, £500 and one-tenth of net profits after 8 per cent. dividend, with the proviso that the whole remuneration of the board shall not exceed £1,000, the same to be divisible.

## CITY NOTES, &c.

**BRAZILIAN SUBMARINE TELEGRAPH COMPANY.**—The receipts of this Company for the week ended November 7th amounted to £5,112.

**THE KELVINSIDE ELECTRICITY COMPANY (LIMITED).**—This Company is this week inviting subscriptions for a second issue of capital, making the capital of the Company £50,000, in 50,000 shares of £1 each. This is payable 2s. 6d. on application, 2s. 6d. on allotment, and the balance, as required, in calls not exceeding 5s., at intervals of not less than three months. The prospectus states that the Company is established to supply electricity for illuminating and other purposes in the district of Kelvinside, the principal residential suburb of Glasgow, and was incorporated in 1889 under the Companies' Acts, with a capital of £10,000, and proceeded with an application to the Board of Trade for a Provisional Order under the Electric Lighting Acts to enable them to supply electricity for lighting purposes, both public and private, in Kelvinside, and bounded by the Burghs of Partick, Hillhead, and Maryhill, and by the Counties of Dunbarton and Renfrew. That Provisional Order was granted by the Board of Trade, and the Bill to confirm it received the Royal Assent on August 14 last. This is the only Company which has powers to supply electricity under the Electric Lighting Acts for the above-mentioned district of Kelvinside. Intending investors are asked to note that the Company have come to an agreement with the Corporation of Glasgow whereby the Corporation, in any Bill to be promoted by them for the annexation of the Kelvinside district to Glasgow, have agreed to insert a clause undertaking not to compete with this Company in the supply of electricity to that district. At the request of the local authority, and in order to efficiently supply the district, the Directors have resolved to increase the capital of the Company from £10,000 to £50,000. There are no unusual engineering difficulties to be overcome in supplying the district. An estimate of the capital outlay and income, which accompanies the prospectus, has been prepared by the electrical engineers of the Company, and it shows that the capital outlay for plant required for a full installation of 30,000 glow lamps will amount to £40,000; but they also give the cost for a first installation of 10,000 glow lamps as amounting to £16,000, the plant for this first installation being put down with a view to its economical extension to the full capacity. None of the shares have been underwritten, and no promotion money has been or will be paid other than the usual brokerage to stockbrokers. The preliminary expenses will be charged against capital. Prospectus and forms of application may be obtained from the Bankers, Brokers, Solicitors, and at the offices of the Company, which are set out on page xvi. of our advertisements.

**MONTEVIDEAN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).**—An extraordinary general meeting of this Company will be held at the offices, Langthorn House, Copthall-avenue, London, E.C., on Tuesday, the 25th inst., at 11.30, when resolutions will be proposed,—That the Company be voluntarily wound up; that Mr. George Fraser, F.C.A., be appointed the liquidator to conduct such winding up; that the Company's undertaking be sold and transferred to the Western and Brazilian Telegraph Company (Limited); and others rendered necessary if the foregoing are carried. We may mention that a meeting of the Western and Brazilian Company was held yesterday (Thursday). A report of the proceedings appears in our present issue.

**SWAN UNITED ELECTRIC LIGHT COMPANY.**—At the meeting of the shareholders of this company, which is to be held on the 25th inst., the Directors will recommend a dividend of 10 per cent. for the year ended September 30th.

**WESTERN AND BRAZILIAN TELEGRAPH COMPANY.**—The traffic receipts of this Company for the week ending November 7, 1890, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company, Limited, were £3,979.

THE NON-CONDUCTOR OF ELECTRICITY.

WAREHOUSE.

VULCANISED FIBRE,
PATENTED.

This new material is supplied in two qualities, Flexible and Hard.

The FLEXIBLE is a substitute for Leather, Rubber, Gutta Percha, &c., and is extensively used by Brass Founders, Axle Makers, Hydraulic, Sanitary, and other Engineers, Pump Makers, Carriage Builders, &c.

It makes the best Hot and Cold Water Packings, and for Axle Washers of all kinds it is unequalled.

The HARD is a substitute for Metals, Hard Wood, Ivory, Vulcanite, Ebonite, &c., and is a good Insulator.

Sold in sheets, 5ft. 6in. by 3ft. 6in., varying in thickness from 1-50in. to 1in.

FLEXIBLE, 2/- per lb.; HARD, 2/3 per lb.

FACTORY.

MOSSES & MITCHELL, 70, Chiswell-st., London, E.C.

# THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

## ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 653.—Vol. XXVI. FRIDAY, NOVEMBER 21, 1890. Price Fourpence.

## NOTES.

After many minor mishaps, which have been occasioned by the inadequate accommodation at the Grosvenor Gallery Station, a most unfortunate accident occurred there last week. The generating machinery was being dismantled, the station was being used as a transformer centre, and a bank of transformers was temporarily erected in the only available place over the boilers and under the water-tank. This place was very dry, and was enclosed by a tarred wooden partition.

At 6.30 last Saturday morning a man who had been in the service of the company for three years, and who was well acquainted with the connections and switches, attempted to change on to a fresh set of transformers so that the others might be free for workmen coming in at 7 o'clock to finish connecting, and it was in trying to carry out this operation that he started an arc at the plug switch. This evidently frightened the man, and he *withdrew* the plug. A 5,000 volt arc was the result, and this set the temporary woodwork and temporary india-rubber covered wires in connection with the plug switches on fire, and in half-an-hour the place was burnt out. A breaking switch was close at hand by which this circuit could have been cut off, and at the end of the room was a main switch by which the whole station would have been disconnected from the Deptford mains. At Deptford, the first intimation received was a drop in the transformed volts to 50; the driver on seeing this immediately shut down. Although it would have been possible to have resumed running almost immediately, it was considered advisable to wait until the engine-room had been cleared out, when the transformers will be placed there. It is expected that the supply will re-commence at the end of this week or early next week. This deplorable accident cannot be said to have arisen from the system employed, but was, in the first place, due to the man losing his head; and, in the second place, to switches, which were of a temporary nature, and capable of being set on fire by an accident. The room itself was fire-proof, so that the damage was limited to the contents, namely, converters and temporary gear erected for distribution purposes. Had the appliances been fire-proof the only result would have been a badly burned switch on a single distributing circuit.

The Grosvenor Gallery Station will form one of four transformer sub-stations, the others being at Trafalgar-square, Victoria, and Blackfriars. The work of generation and of distribution thus stopped had been proceeding with highly satisfactory results. The load has been considerably higher than that which was generated at the Grosvenor Gallery, but both the coal bill and the wages have been reduced to about one-half. The arrangements for parallel running are now complete, and the huge dynamos are without any difficulty run together, keeping each other rigidly in step. So perfect is the synchronism that when the dynamos were running at the Grosvenor Station, they were thrown on to the same mains as those at Deptford, and both contributed their yield of energy to the circuit. The older pattern of transformers which have been in use at the station are being replaced by an improved pattern, in which the drop in pressure is only one per cent.

To discuss with justice and pertinence a paper which contains so much new information, and one recording so much work as that which was presented by Prof. Ayrton to the Institution of Electrical Engineers last week, it is at least necessary that the audience should hear the paper read, or have a printed copy before them. The nature of the subject and the time precluded the former, and we regret that we are unable to present the latter to our readers in this issue. The "authorised abstract" of the discussion, which we hold over until the paper itself is published, contains a very meagre reference to two points in Mr. Crompton's remarks, and we are indebted to him for the following information about the proof-plate, and the irreducible sulphate.

The proof-plate for use with accumulators consists of a small accumulator plate kept charged in a separate cell. A fully charged positive proof plate is used to test the negatives of a discharged cell, and a fully charged negative proof to test the positives of a discharged cell. If when a cell is discharged the full volts are found between its positive and a proof negative, then the negatives are said to have run down, or are deficient in capacity, and *vice versa*. The period of discharge during which sulphate is formed, and the position in which it is formed, has a great deal to do with its reducibility; and this has, Mr. Crompton thinks, no doubt given rise to the belief that there are two kinds of sulphate, one of them irreducible. If a current is still passed through a cell, of which the negative plates have run down, in the same direction (owing to it being coupled in series with other cells), there comes a time when there is no longer any electrical stress in the electrolyte. Under these conditions ordinary chemical

Digitized by Google

affinities come into play. The positive plate becomes sulphated from mere contact with the electrolyte, that is to say, at the outer surfaces. This sulphate may not be in electrical contact with the lead backing, and consequently can never be reduced. It only gets pushed off, and falls down to the bottom of the cells. The ordinary sulphate is probably formed at the inner boundaries—that is to say, between the active material and the lead backing—and is consequently in electrical contact with the backing, and is easily reduced during charge.

---

MR. TESLA favours us this week with a valuable letter describing his views on the losses which occur in transformers. His communication is particularly important, as the different points of this intricate subject are explained at some length in order to avoid the possibility of misconception. Statements made about magnetomotive force are apt to be misleading unless very explicitly made, as the analogy between the magnetic and electric circuits is liable to incline us to regard the former in too simple a way. Electric currents are easy to deal with because, as MR. CROMPTON recently observed, they can be canalized or confined to definite channels, while the flux of magnetic lines of force can take place through all known substances, and in consequence all magnetic circuits are very complex. Both electromotive and magnetomotive forces are in general located in a particular part of the circuit to which they refer, in the former case they are to be found in the battery or dynamo, and in the latter in the magnetising coils. When, however, we attempt to distribute the potential around the circuit, a difference between the two cases is at once manifest; for whereas with the electric circuit owing to its simplicity, it is easy to see how the volts are distributed, the magnetic circuit is much harder to deal with owing to the great number of the branch currents. For this reason it appears better to avoid the use of the term magnetomotive force per unit length.

---

THE remarks made by Mr. TESLA about the constancy of the magnetomotive force for different loads on the secondary seem especially suggestive. It is, in fact, not difficult to see that with transformers which regulate well at constant potential, the hysteresis and eddy current losses must be practically the same for all currents. The volts induced in the secondary circuit cannot differ much from the pressure at the terminals, since the resistance of the secondary coil of all ordinary transformers is negligibly small. The number of volts induced in the secondary, and hence the flux of lines in the magnetic circuit of every transformer regulating for constant pressure, must thus be independent of the load. It follows that the hysteresis and other losses are constant as regards the load, and must therefore be the same as when the secondary circuit is open. The same remark applies to the resultant exciting current due to the combined action of the primary and secondary coils; and it thus becomes a simple and definite problem to determine the relation which connects the magnitude of the primary and secondary currents with the difference of phase which must exist between them, so that the effective ampere turns may be independent of the load.

THE methods of measuring the impedance and self-induction of alternate-current apparatus, described by Mr. STEINMETZ in this issue, are worthy of attention, since they need but the ordinary testing implements at hand in the factory or dynamo room, and no particular skill is required to carry them out. Ballistic galvanometer methods are quite unsuitable for such measurements, since this instrument is unfitted for use in factories, and is not in general sufficiently sensitive. Moreover, the results obtained by using steady or transient currents are seldom applicable for alternate current work when iron is present in the coils tested. In the methods described, alternate currents of the usual frequencies are passed through the apparatus under examination, and the coefficient is deduced from the readings of an ammeter and Cardew voltmeter. There is no special novelty in the process, as it is but a slight modification of an old method of JOUBERT'S, which has hitherto received very little of the notice it deserves. The manner in which the formulæ have been obtained, and the practical shape in which they have been put, is, however, important, and the experimental examples given will render the application of the methods clear. The process for finding the self-induction of choking coils and other inductive resistances appears to be excellent, but the method for determining the inductive constants of measuring instruments seems of little practical value. The formula given is seen to be a complicated expression involving five quantities, each of which has to be observed, and an error in any one of which will seriously affect the result. The values so obtained for the self-induction cannot be relied on, even if the ammeters and voltmeters used read as accurately as Mr. STEINMETZ'S numbers appear to claim. Instruments which read a current of ·3478 amperes, correct to the last figure, are too rare as yet to "have come into general use" in the factory. With ordinary instruments the second figure is always uncertain, and under these circumstances the results by this method obtained could not be trusted.

---

WE are glad to learn that the Central London Railway Company, nothing daunted by the rejection of their scheme last session by the Select Committee of the House of Lords, propose to renew the attack. Few districts of London are more completely isolated, so far as concerns direct railway communication with the City, than Bayswater, and the proposed line, apart from any benefits it may confer on the inhabitants of that quarter, will be a distinct public improvement, since it can hardly fail to divert a large proportion of the omnibus traffic at present encumbering Oxford-street to routes less busy, and where electricity does not compete. We trust that by the time the Company's Bill again comes before the Parliamentary inquisitors, the success of the City and South London line will have discounted the dismal forebodings of landowners, shopowners, and bishops

---

ANOTHER Bill which is to be re-introduced this Session is the London Overhead Wires Bill, by which powers to remove, register, inspect, and regulate overhead wires in the Metropolis is conferred upon the London County Council. Now that practically nothing but statutory electric lighting is being carried on in

Digitized by Google

London, the Bill of the County Council would appear at first sight to be aimed at the National Telephone Company; but since power is also asked "to provide for the attachment of overhead wires to houses or buildings, and the carrying of wires over land and buildings in certain cases where it is necessary for the extension of telephonic communications, and to provide for determining and assessing the compensation to be paid to the owners or occupiers of the houses, buildings, or land in respect thereof," there is, apparently, nobody left but the Postmaster-General for the Council to fall foul of. However, whether or not there is any immediate necessity for a London Overhead Wires Bill, it is but right that some such powers of regulation and inspection should be conferred on the Municipal Authorities.

**Personal.**—Lord Rayleigh has been appointed an honorary member of the Bavarian Royal Academy of Science.

**Harrogate.**—At the last meeting of the Town Council it was decided to light the whole of the town by electricity.

**Leeds.**—The Leeds County Council have decided to allow a trial of some Thomson-Houston electric cars on the Roundhay Park tramway.

**Institution of Electrical Engineers.**—No students' meeting will be held as advertised. On the 5th proximo Mr. Garret will read a paper on "Search-Light work."

**National Telephone Company.**—This Company announces that the trunk line between London, Manchester, Liverpool, and Birmingham, is now open to the public.

**Stockport.**—The Corporation have given notice of their intention to apply for an Electric Lighting Provisional Order. The gas works are under the management of the Corporation.

**Bombay.**—The Bombay Municipality has called for tenders, up to February 16, 1891, for the experimental lighting by electricity of certain streets in the city for a period of two years.

**Indian Telegraph Department.**—The Government of India has sanctioned an expenditure of one and a-half lakhs for the repair of the overland telegraph line to Persia, the insulation of which is defective.

**Southport.**—The Corporation have given the usual notices of their intention to promote in Parliament next Session a Provisional Order empowering them to supply electricity for lighting and other purposes.

**The Elektricitats Zeitung.**—This paper, which has recently passed into the hands of Herr Arthur Wilke, will in future appear three times instead of twice weekly, and the editor announces that he will endeavour shortly to bring it out daily.

**"Darkest England and the Way Out."**—The staff and men in the dynamo department of Messrs. Goolden & Co.'s works resolved to raise a subscription to aid General Booth's scheme. The sum of six guineas was in a few hours collected, and forwarded last Saturday to General Booth.

**A New Use for the Telephone.**—The latest application of the telephone is to place the wards of the City Hospital, New York, and the reception-rooms in telephonic communication, so that patients suffering from infectious maladies may safely communicate with their visitors.

**Gelatinous Electrolyte for Storage Batteries—A Correction.**—On p. 47 of our last issue it was stated that "during the last months *The Electrician* twice mentioned the 'gelatinous electrolyte' (August 12th and September 10th)." These dates should be July 11th, p. 253; and April 25th, p. 213.

**The Board of Trade Overhead Wire Rules.**—We understand that Mr. Crompton has laid the whole case of the action of the Board of Trade with regard to overhead rules before the General Council of the London Chamber of Commerce, and it has been decided to write a strong letter to the Board of Trade requesting them to receive a deputation on the subject.

**Newcastle-on-Tyne.**—On Wednesday afternoon last week, between twelve and one, a puff of smoke was observed to issue from a junction-box of the Newcastle-upon-Tyne Electric Supply Company's mains (the same one that blew off a few days previous). Nothing further happened to this box, but the covers of two other boxes in the locality almost immediately blew off. No one was injured.

**Madame Tussaud and Sons.**—This popular Gallery has recently been provided with a well-arranged plant for supplying its own electric light. The work has been carried out by Messrs. Drake and Gorham, Mr. Kapp acting as consulting engineer. The lighting was inaugurated on Wednesday last, and will, no doubt, prove to be very valuable to the proprietors on account of its cleanliness as well as comfort.

**A Chair of Industrial Electricity.**—The Minister of Commerce has just created, at the Conservatoire of Arts and Sciences, a chair of industrial electricity, and the Académie des Sciences was invited to present a list of candidates for the new chair. There were three candidates for the post, MM. Marcel Deprez, Hospitalier, and Mercadier, and the President of the Republic, upon the recommendation of the Académie des Sciences, nominated M. Marcel Deprez.

**Edinburgh Exhibition.**—Judgment was given last week in the Second Division of the Court of Session, as to the winding up of the association. Lord Young, in giving the opinion of the Court, said: We have considered this case, and we are all of opinion that the voluntary liquidation which is going on just now is lawful, and that there are no sufficient reasons why we should interfere with it by putting the association under another form of liquidation and another liquidator.

**Electric Traction.**—The Hammersmith Vestry, at its meeting last night, unanimously agreed to the proposal of the West Metropolitan Tramway Company to work the line from the Uxbridge-road Station to Kew, a distance of three miles, by the Lineff system of electrical traction. Reports by Mr. W. H. Preece, chief electrician to the Post Office, Mr. Gisbert Kapp, C.E., and Prof. Robinson, approving of the Lineff system, were laid before the Vestry. It is understood that the work will be commenced without delay.

**Old Students' Association.**—A Cinderella Dance will be held at the Westminster Town Hall, on Friday, December 12th. Tickets, 3s. 6d. each, may be obtained from Miss Walter, 38, Woodbury-Grove, Finsbury Park, N.; Dr. W. E. Sumpner, Central Institution, South Kensington; H. B. Bourne, 41, Priory-road, Bedford Park, W.; or any other of the members of the committee, or from Reginald J. Jones, Hon. Sec., care of Messrs. Woodhouse and Rawson United (Limited), 88, Queen Victoria-street, London, E.C. The number of tickets being strictly limited, early application is desirable.

**Bath.**—At a meeting of the Town Council last week a report by the Electric Lighting Committee was read. Mr. Sturges advocated an independent inspection by a leading electrician. He also stated that the Board of Trade insisted on inserting a paragraph in Mr. Massingham's licence that he should not be compelled to sell at the end of seven years if he wanted an extension. Mr. Massingham was perfectly willing not to have such a clause, but the Board of Trade said he should have it. It was decided that as the question at issue with the Board of Trade was not pressing it should be deferred, and it was unanimously decided to have the works inspected by an expert.

**Institution of Electrical Engineers.**—The *conversazione* given on Wednesday evening last in the Galleries of the Royal Institute of Painters in Water Colours by the President and Mrs. John Hopkinson was of a very successful character. The attendance was unusually large, over 1,000 being present, and the additional room afforded by making use of Prince's Hall was, in consequence, greatly appreciated. Amongst those present were Sir Richard Webster, M.P., Sir James Anderson, Sir James Douglass, Sir Douglas Galton, Sir Albert Cappel, Sir Henry Mance, Sir David Salomons, Bart., Prof. Perry, Prof. Ayrton, Prof. Silvanus Thompson, Mr. C. E. Spagnoletti, Prof.

Digitized by Google

G. C. Foster, Major-General C. E. Webber, Colonel Sir Charles Wilson, Sir G. Barclay Bruce, Mr. Latimer Clark, Sir Benjamin Baker, Sir Frederick Pollock, Dr. Coleman Sellers, Prof. W. D. Niven, Mr. John Aird, M.P., Prof. J. W. Groves, Rt. Hon. Sir Edward Fry, Prof. J. Thomson, F.R.S., Dr. J. H. Gladstone, F.R.S., Sir F. Abel, Mr. J. W. Swan, &c., &c.

**The Northfleet Series Tramway.**—The technical and commercial merits of the series system of electrical traction, as exemplified at Northfleet, having been ascertained from the operation of the line for the last eighteen months, it has been decided to discontinue running. We are informed by the Electrical Engineering Corporation that the line, as is well known, was for demonstrative purposes only, and that, in their opinion, its object having now been attained, they see no further reason for incurring the large expense necessitated by the smallness of the local traffic, and the heavy rental and charges imposed by the Gravesend, Rosherville, and Northfleet Tramway Co., through whom the Parliamentary powers were obtained. Careful accounts have been kept of the cost of running for the last six months, and from these, when audited, the actual cost of motive power on the series system will be made public. To this, we hope, will be added a report upon the degree of success which has been attained.

**Electric Railroading at Buffalo, N.Y.**—The following figures with regard to the passengers carried by the Park electric system of the Buffalo Street Railroad Company may prove of interest. There are four cars running on this branch, which is about one and three-quarter miles in length. On July 16th 17,000 passengers were carried; July 27th, 11,000; August 25th, 10,000. This road is equipped upon the Edison system, and has been in operation now for about fifteen months. The largest load ever carried was a little over twenty thousand, the occasion being a picnic, and the time being two days after the road commenced operation in July, 1889. Only three motor cars were in service on that day, and this remains the greatest record ever made by that number of cars.

**Telephone Extensions in Devonshire.**—A few months ago the Western Counties and South Wales Telephone Company were approached by the Port of Plymouth Chamber of Commerce with a view to establishing a signal station on Rame Head for reporting by telephone to Plymouth all vessels passing up or down Channel or entering the port, as well as casualties and other shipping news of interest. The Company have so far met the wishes of the Chamber that the connection with Rame Head is almost completed, and, provided that arrangements can be made with the Admiralty, the station will be in working order in a few weeks. The Company have now a connection with the Plymouth post-office, whereby subscribers can, in arrangement with the Company, transmit and receive their telegrams by telephone without the inconvenience and delay of sending them by hand.

**Royal Society.**—The following papers were down for reading at the Royal Society, on Thursday, Professor J. V. Jones "On the Determination of the Specific Resistance of Mercury in Absolute Measure." Dr. Hopkinson, F.R.S., "Magnetism and Recalescence."—The following is the list of names recommended by the President and Council of the Royal Society for election into the council for the year 1891: President, Sir William Thomson; treasurer, John Evans; secretaries, Prof. Michael Foster and Lord Rayleigh; foreign secretary, Archibald Geikie; other members of the council, Prof. W. E. Ayrton, W. E. M. Christie, Prof. W. Boyd Dawkins, J. W. L. Glaisher, D.Sc., Hugo Müller, Prof. Alfred Newton, Sir William Roberts, M.D., W. Chandler Roberts-Austen, Prof. E. A. Schäfer, Sir George Gabriel Stokes, Lieut.-Gen. Richard Strachey, R.E., Prof. J. J. Thomson, Prof. T. E. Thorpe, Sir William Turner, M.D., Prof. S. Howard Vynes, and Gen. J. T. Walker, C.B.

**The Life and Price of Glow Lamps.**—A correspondent points out that before being able to attach any practical value to Mr. Lott's statement in our last issue, it is necessary to have figures as to the watts per candle-power that this lamp required initially and after burning 10,000 hours. It is quite practicable for either a series or multiple glow lamp to burn considerably over 10,000 hours if he always kept a low efficiency, say, of 5 watts per candle-power and below. If the particular lamp mentioned by Mr. Lott began at, say, 3 watts per candle-power, and after 10,000 hours even went up to 4 watts per candle-power, then this denoted an excellent result. Our correspondent adds, with reference to our note on the price of lamps, that he is supplying lamps (made within 300 miles of London) at the still lower price of 1s. 7d., fitted and delivered free, and there is still every prospect of lowering this price in the near future.

**St. Martin's Vestry v. Gordon.**—This case, which was an appeal from the decision of the Divisional Court, was heard before Appeal Court I. on Monday this week. Mr. Gordon is the proprietor of the Hotel Métropole, and the question raised was whether the vestry were bound, under the Metropolis Local Management Act, 1885, to remove, in the ordinary course, the clinkers and other refuse produced in the furnaces erected in the hotel for the purpose of supplying the electric lighting, &c., of the hotel. The vestry contended that the clinkers were the "refuse of a trade" within the meaning of the Act, and therefore that they were not bound to remove them without payment of a reasonable sum for so doing. The Divisional Court held that the clinkers were not the refuse of a trade, and that the vestry were bound to remove them without payment. The Appeal Court dismissed the appeal, the Court being of opinion that in no case could "ashes" be held to be the "refuse of a trade."

**Reduction of Telephone Rates.**—The National Telephone Company has intimated to the subscribers to the Liverpool and Birkenhead exchanges that the rate of annual subscription will be reduced on and after January 1, 1891, from £15 to £10 for a connection within the customary radius. The trunk line tariff will, after January 1, 1891, be revised, the charges for three minutes' conversation being as under, to exchange subscribers only, no reduction being made to non-subscribers:—For any distance not exceeding 25 miles, 3d; over 25 miles and not exceeding 50, 6d.; over 50 miles and not exceeding 75, 9d.; over 75 miles and not exceeding 100, 1s.; over 100 miles and not exceeding 125, 1s. 6d.; over 125 miles and not exceeding 150, 2s.; over 150 miles and not exceeding 175, 2s. 6d.; over 175 miles and not exceeding 200, 3s. The National Telephone Company has also intimated that on and after January 1st next, local subscriptions will be reduced at Newcastle from £12 to £10, also that the trunk line tariff will also be considerably reduced on and after the date named.

**The Candle-power Classification of Arc Lamps.**—With a view of demonstrating the meaningless nature of the present commercial candle-power classification of arc lamps, M. Hospitalier publishes in a recent issue of *l'Electricien* the nominal illuminating power of arc lamps by different makers, but taking the same current. The following are some of the figures reduced to English candles contained in M. Hospitalier's table:—

| Amps. | Sautter-Lemonnier. | Fontaine | Cance (Globe). | Schuckert. | Cr'mpt'n | Latimer-Clark. | Ball. | By Tischendorffer's Formula. |
|---|---|---|---|---|---|---|---|---|
| 5 | 350 | 500 | 300 | ... | 500 | 400 | ... | ... |
| 8 | ... | 1,000 | 450 | 1,250 | 1,000 | ... | 1,600 | 1,250 |
| 10 | ... | ... | Breguet 700 | 1,750 | 1,400 | 1,500 | 2,000 | 1,780 |
| 12 | ... | ... | ... | 2,500 | ... | ... | ... | 2,375 |
| 13 | 1,500 | ... | ... | ... | ... | ... | ... | ... |
| 14 | ... | ... | ... | ... | ... | ... | ... | 2,930 |
| 15 | ... | 2,000 | ... | ... | ... | 3,000 | ... | ... |
| 20 | ... | ... | 1,500 | 5,000 | 4,000 | ... | ... | 5,375 |

**Hydro-Electric Installation at Antwerp.**—At the time when various schemes for the electric lighting of Brussels were under consideration (see *Electrician*, October 11 and November 1, 1889), M. Van Rysselberghe produced a plan, which was much discussed, for distributing power by hydraulic pressure to turbines placed in the basements of the buildings to be lighted, the turbines being coupled direct to the spindle of the dynamos In this connection the following description of a miniature installation laid down by M. Van Rysselberghe on this plan at Antwerp may be of interest. The installation is situated at the hydraulic station connected with the Antwerp dock-locks, and cranes and water at 40 atmospheres pressure is obtainable. The turbine devised by M. Van Rysselberghe is of the "hydrau-

Digitized by Google

lic tourniquet" description, and is coupled direct to a four-pole Victoria machine, the spindle of which is vertical. At full load 7 electrical horse-power are given out by the dynamo for every 16 horse-power supplied to the hydraulic motor. The speed is kept very constant at 650 revolutions by an automatic governor which regulates the admission of water. The hydraulic motor consumes three litres of water per 16 horse-power per second, and as the price of it is ·1d. per cubic metre, the cost of the horse-power hour at the dynamo terminals is about 2d. The dynamo supplies current to the four arcs and 150 incandescents employed in lighting the hydraulic station.

**A Novel Form of Measuring Instrument.**—In a recent issue of *La Lumière Electrique*, M. F. Leconte gives a brief account of some experiments carried out by him at the Liége University with a view of testing a curious form of electrical measuring instrument. M. Leconte's idea is to make a pile of circular iron discs, interposing some springy substance, between each disc, and to place this pile inside a solenoid. When the solenoid is traversed by a current, the pile of discs tends to contract owing to the formation of unlike magnetic poles at the opposing surfaces of the discs. This contraction is resisted by the springs, and by means of a suitable magnifying device the movement of a pointer along a suitably graduated scale enables one to read off the volts or the amperes. M. Leconte employed discs ranging in number from 18 to 60, in diameter (1mm. = 40 mils) from 20mm. to 65mm., and in thickness from ·2mm. to 8mm. Amongst the substances employed as springs were watch-spring steel, blotting paper, packing paper, ordinary paper, flannel and black indiarubber. The tendency of the discs to move sideways was checked by punching holes through them and slipping them over vertical glass rods. The sensitiveness of such an apparatus can be increased either by adding to the number of the discs, augmenting their surface, or by providing the solenoid with a core of iron wire. M. Leconte gives curves of the scale readings obtained with a voltmeter arranged with 18 cast-iron discs, 8mm. thick, and 65mm. in diameter, and provided first with indiarubber springs and then with steel springs. The curve in the first case was fairly regular between 27 and 53 volts, with steel springs the curve was very irregular, with indiarubber springs the deviation of the scale index was only 18mm. for 57 volts, and the actual contraction of the column of discs was only 2mm.; with steel springs the index deviation was only 8mm. for 50 volts.

**Electricity in the Service of the Chicago Fire Underwriters.**—Several months ago the inspection department of the Chicago Fire Underwriters' Association, says the *Western Electrician*, decided to establish a test department for the purpose of experimenting with automatic sprinkling apparatus. As in making the experiments it would be necessary to employ a convenient and easily-handled heating apparatus, and also to have a well-lighted room and a small power plant, it was decided to use electricity as a heating agent as well as for furnishing light and power. Arrangements were therefore made to construct an electric heater to be operated by current from the Edison Company's 220-volt circuit. The pipe sprinkler runs into a zinc-lined water-tight apartment. At the centre is the electric heating device, a metallic box, measuring 12 by 12 by 12in. The switch to control the current is on the outside of the apartment. The heater, when in operation, takes on an average 16 amperes. In the ceiling, with its bulb set just above the sprinkler on the end of the pipe, is a mercurial thermometer which will indicate a temperature from freezing point to 465 degrees. This instrument is so arranged that its indications may be read on the outside of the apartment. The room is well lighted by incandescent lamps, and small windows in the side of the rooms permit a close observation of the action of the sprinkler. When a sprinkler is to be tested it is only necessary to attach it to the end of the pipe, and by means of the cords to hoist the heater until it incloses the sprinkler. Current is then turned on until the temperature rises to the point at which the sprinkler opens. After this the heater is lowered and the form of the water jets may then be closely observed. A temperature of 221 degrees at the sprinkler has been attained through the use of the method, and a higher degree of heat could be obtained. The sprinklers, however, are designed to open at about 155 degrees.

**The Lubrication of Steam Engines.**—The following is extracted from an interesting article on this subject which appeared in a recent issue of the *Engineer*: Engineers very commonly pay scant attention to the cost of oil used in lubricating steam engines. They regard it as an insignificant item. Even those who pay for the oil take small pains to ascertain whether they are paying more than need be paid. The results of an inquiry into the question of oil bills in any district would, we venture to say, give highly startling results. Not long since we were shown an American engine of the horizontal high speed type. It was indicating about 13 or 14 horse-power. Coal was very cheap, and we were told that the cost of fuel was as nearly as might be 1s. 6d. a day. The oil bill was 3s. 6d. a day, or more than twice the cost of coal. In another instance we found an engine indicating about 1,500 horse-power and using 120 gallons of oil per week. A marine engine, triple expansion, of the same power gets on with 20 gallons a week. Again, we find in some cases that oil costing 2s. 6d. a gallon is used; in others, for just the same class of work, about 9d. a gallon is paid. It will readily be seen that a lavish use of oil at 2s. a gallon runs into a great deal of money. It is high time, we think, that more attention was given to this subject than has hitherto been devoted to it by users of steam machinery. The chief causes of excessive oil consumption are —says our contemporary—firstly, that engineers or drivers in charge of engines care nothing about oil waste; secondly, badly designed or badly kept engines; thirdly, unsuitable oil; fourthly, running in dusty places; fifthly, defective lubricating apparatus.

**Experiments on Electrical Oscillations.**—Professor John Trowbridge and W. C. Sabine, of Harvard University, have, says the *Electrical World*, recently been experimenting on electrical oscillations, and their results are interesting. The fundamental experiment consisted in obtaining a rapidly oscillating discharge from a Leyden jar and photographing the oscillations by making the spark fall on a revolving mirror. In reasoning on the mode of electrical oscillations in dielectrics, it occurred to the authors that the particular dielectric medium must influence the result obtained. The condensers employed were concentric cylinders of zinc, of which the capacity could be quite readily computed. The condenser was furnished with a discharging circuit about 50 feet in length, and was charged by a Holtz machine. The revolving mirror was spinning on a horizontal axis at the speed of 3,000 revolutions per minute. The period of the oscillations was, approximately, two or three millionths of a second. Glass Leyden jars were tested in addition to the air condensers. With the air condenser there was found a singular variation in the times of successive oscillations. It might have been expected that glass would be much more likely to show such variations. On the contrary, the periods of the discharges from the glass condenser were extraordinarily regular, while those in the air showed decided discrepancies from the theoretical time of oscillation as determined from the capacity of the condensers and the self-induction of the circuit. With small air condensers the variations were more marked than with large. According to the authors the reason the phenomenon was not observed in glass was because the period of recovery from a strain in that dielectric is too long to show itself during the enormously rapid oscillations with which the experiments were tried. The conclusion reached was, that, in the first place, the electrical oscillations in air show a certain periodicity in their lengths, due to the incomplete recovery of the air from the electrical strain. It also appears that there is a certain amount of the energy of the discharge spent in overcoming the dielectric viscosity of the air, just as a certain amount of energy is spent in hysteresis in a magnet. A further experiment was tried by the authors with a view of testing the effect of an intense magnetic field on these electric waves. The results, however, were indecisive. We may mention that these conclusions were criticised at the recent meeting of the British Association by Dr. Oliver Lodge, who pointed out that the capacity of the leads was able to produce results very similar to those observed.

## AN IDEAL PHYSICAL LABORATORY FOR A COLLEGE.

BY PROF. OLIVER LODGE.

(*Concluded from page* 33.)

Coming nearer to the details of internal arrangement of the block-plan, published last week, we may as well consider each of the main blocks separately, considering them as something like 40ft. cubes.

### The Students' Laboratory.

Take first the students' laboratory. The ground floor, as being steadiest, should accommodate the senior or second and third year students. Benches round the walls under the windows, with a gap here and there to give direct access to wall itself, and tables in the middle of the room, some fixed and very steady, others movable so as to leave either a clear space or to enlarge the fixed tables at pleasure, seem the main fittings wanted (Fig. 4). The non-window wall would be left free for fixtures and wall apparatus generally. Every bench and table 3ft. high and, say, 2½ft. broad. All the fixed ones to be provided with gas and water and electricity, and several of them with exhaust or vacuum pipes, compressed air, steam, temperature and pressure regulators, small turbines or other motors, and fume chamber ventilation. Galvanometers and lamps and scales on wall brackets.

The junior students' laboratory on the first floor would contain simple tables placed so as to get a good view of a slightly raised lecturer's or demonstrator's table, whence the student could be instructed what to do every now and then (Fig. 5). Each table might have a gallows frame along its middle, for the purpose of supporting things conveniently.

Above this, again, there might be another floor partitioned off lightly into rooms of various size, to accommodate a limited number of advanced students engaged in research, and each provided with a key to lock up the contents of their respective rooms (Fig. 6). By means of benches supported by very substantial brackets from the walls, without touching the floor, very fair steadiness can be obtained; though, of course, for anything demanding a high degree of rigidity, the ground floor is more suitable. Still, there are contrivances for securing steadiness on an elevated floor, and these are mentioned in connection with the research laboratory.

### The Electrical Laboratory.

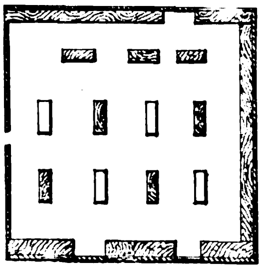
The electro-technical department is also mainly a students' laboratory, and may be considered next. The ground floor is to hold the heavy apparatus, say three or four experimental direct-current dynamos, a couple of alternating machines with their exciters, dynamometers, speed varying gearing, &c.; the shafting being driven either by an engine on the spot, or preferably by a large dynamo used as a motor, and supplied with current by a similar machine driven from a steam-engine in the neighbouring engineering department, where there will naturally be steam always up. This plan will save the danger and trouble of a local boiler, or the inconvenience which gas-engines present when used for experimental purposes; and it would besides give the students some experience of fairly large-scale transmission of power and of the tests to be made at both sending and receiving ends. The storage battery would be established in a well-lighted, well-ventilated, partitioned off, central compartment, whence groups of wires would lead to switchboards in various parts of the building. Various engine room meters would be provided on the ground floor; but the more delicate and elaborate testing instruments, Thomson meters, and such like, together with transformers, lamps, and experimental devices of all sorts, would be accommodated on the first floor above. On an upper floor, again, I should propose a telegraphic laboratory, with artificial cables and a syphon recorder, in addition to the more refined kinds of apparatus in use on land lines, and the ordinary electrical fittings of a laboratory. An experimental land line, with specially arranged resistance and leakage, and with a variety of faults to be introduced by the demonstrator and detected by the student, could also be planned.

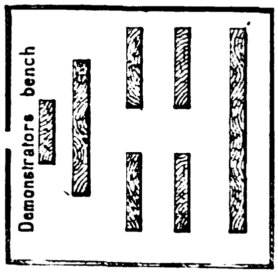
### The Theatre.

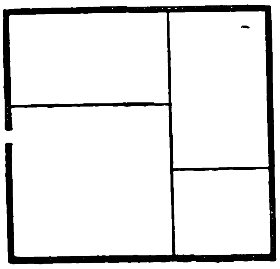
Not much need be said about the theatre. It should be a lofty room, say about 30ft. high, with a large lecture table plentifully supplied with every convenience already mentioned as desirable for some of the senior students' work benches, and likewise containing a large tank with plate glass front, a mercury trough, strips let into it for supplying current from a storage battery, with switchboard to vary the number of cells connected, and so on. Diagram frames, lantern screen, fume chamber, wall slates, &c., go without saying. An oxygen tank, easily controlled by water taps and supplying the gas to various parts of the table for local oxy-coal-gas lamps, is also useful. So is an electric lantern conveniently situated and always ready. For exhibiting lantern slides I prefer a translucent screen of small size (about a yard square), on which strong illumination is thrown by a short-focussed lens from behind. The room need not be darkened, only shaded from direct sunshine. I have been accustomed to show lantern slides in this fashion for some years and find it extremely convenient. To darken a room so that students cannot take notes or see the blackboard and other diagrams is a very unsatisfactory plan. Stray light *behind* a translucent screen is to be avoided, but stray light in front penetrates it, and does no particular harm. It is necessary with such a screen to point the light towards the middle of the audience, and persons very much on one side will lose some light; but there is usually no practical difficulty in securing plenty for all. Even to a large audience a brightly-illuminated small picture is often quite as effective as a large dim one. The size of the room, however, must, of course, be taken into account, and the amount of darkness necessary varies accordingly.

The best place for artificial light at night is frequently near the back of the audience; it illuminates their books then without glaring into their eyes. The table, blackboard, and diagrams, can be illuminated from above by screened lamps under the control of the lecturer's assistant. Near the top of the room an experimental gallery, with slotted uprights to its baluster for suspending things from, and for helping the performance of various lofty experiments, is a valuable addition. The best place for the outgoing ventilation shafts is probably near the back of the ceiling, fresh air entering from under the lecture table on the lecturer's side, its temperature and volume being under control, so that the foul air can be drawn away from the lecture table, which for some experiments it is desirable to protect from the damp of an audience.

In addition to the main lecture theatre, a class-room for exercises and more mathematical work is essential, especially as the illustrated lectures involve a good deal of preparation, and the lecture theatre is therefore not always available for







Students' Laboratory.

Fig. 4.—Ground Floor, for Senior Students. Fig. 5.—First Floor, for Junior Students. Fig. 6.—Second Floor, for Advanced Students.

the multitude of classes that have to be held. A floor high up, above the theatre, seems the place where such a classroom must be placed, though a lower position would have been preferable.

THE RESEARCH LABORATORY.

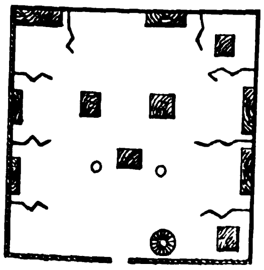
Now we come to the place where the Professor carries on his own private work, and the endowment of which usually constitutes the inducement to associate himself with a college at all. There may be many differences of opinion as to what is best for a research laboratory. Some may prefer a set of small rooms, others one large room. My own inclination leads me strongly in the latter direction; I have found one large room by far the best plan. Of the block called "research laboratory," the ground floor is the principal portion; it, in fact, constitutes the laboratory, with a supplementary floor high up, and a couple of galleries in between. A large lofty room has great advantages; it is inconvenient to be cramped in any dimension.

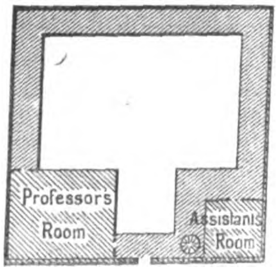
A large amount of unoccupied wall space is left in this laboratory for the accommodation of tall mercury gauges, suspended wires, long tubes, and a multitude of other things conveniently fixed and reared against a wall. Slotted poles, or "Willis's posts," of considerable height, fixed against a wall with a space large enough for the hand to clamp special iron brackets (supplied by Rigg, of Chester) to them, I find excessively convenient for supporting things firmly. Similar, but shorter, slotted posts are useful also in the students' laboratory, above several of the side benches. They are unobtrusive when not wanted, and they often save the necessity for inconvenient retort stands and other holders standing unsteadily about. To get at these carpentered up; but to make it still easier I propose a set of folding screens, 8 or 10ft. high, hinged and shutting up into the wall like shutters when not in use, but able to be drawn out so as to make a stall or little room, which can then be secured with a padlock if desired (Fig. 7).

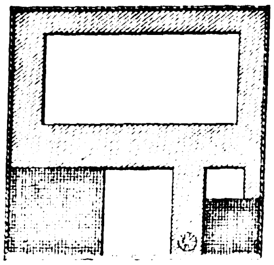
Every window throughout the building ought to be provided with obscure blinds, and those in the theatre and research laboratory ought to be thoroughly opaque, so that complete darkness can be secured when wanted; but when only local darkness or considerable shade is needed, the partitions already spoken of enable it to be obtained with little more than a black cloth thrown over their top.

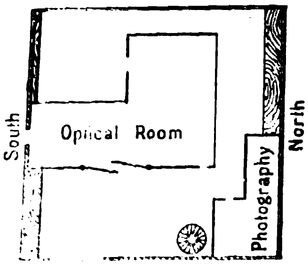
The main difference between the research laboratory and the senior students' laboratory is that, whereas in the latter all manner of appliances are located in permanent positions, water pumps, turbines, gas furnaces, sand-baths, steam-heaters, gas cooking stoves, and the like; in the research laboratory permanent fixtures are few: things are to be brought from the museum and rigged up in the most convenient position for the particular investigations going on, and when they are done with after a few years they can be dismantled and moved elsewhere, or else stored until they are wanted again. The difference may be emphasised thus:—A student is to be moved to the apparatus adapted to the particular experiment given him to do during the next few days or weeks. Apparatus is to be moved to the person engaged in research and established in some semi-permanent manner for the year or two during which the investigation lasts.

Although a lofty room is needed for some experiments, it is not necessary to have it equally free all over, and accordingly









RESEARCH LABORATORY.

Fig. 7.—Ground Floor. Fig. 8.—Twelve feet up, Private Rooms and Main Gallery. Fig. 9.—Twenty-four feet up, Upper Gallery. Fig. 10.—Top Floor.

poles, gauges, and other appliances, the two galleries are available. The poles penetrate the galleries, leaving a clear space a foot or so square round them; but the galleries are five feet broad, and accordingly there is plenty of room to pass. Short library ladders in each gallery permit every point of the entire wall to be readily accessible. The front uprights of the gallery, both here and in the lecture theatre, are also slotted for hanging things from brackets for experiments going on below.

The tables in the research laboratory will most of them be movable, there must always be plenty of ordinary wooden tables standing about, but a few masonry piers built direct on the rock beneath, which is not to be cut away but if necessary levelled up by concrete to within a foot or so of the boarded floor, are provided here and there; and more can be put down temporarily wherever wanted. A spiral staircase and a couple of pillars for supporting some rooms above are also shown on the plan. These pillars should not be iron or faience or anything ornamental, but should be simple baulks of timber, so that things can be easily attached to them. The walls, also, it is very pleasant to have substantially wood-panelled up to a certain height, so that screws, hooks, &c., &c., can be immediately put in at any place without the trouble of plugging. The water and gas pipes, and the electric wires, should not be hidden away, but should be readily accessible along their whole length, so that they can be tapped at any convenient place, in addition to the fixed stop-cocks provided.

Although a large lofty room is favourable for many experiments, yet there are occasions when it is desirable to enclose something or to partition it off from the laboratory for a month or two; for instance, an experiment which needs a long time for its development. Such partition can always be lightly at about 12ft. elevation I propose to place the professors and the chief assistants' private rooms, as shown in Fig. 8. The professor thus gets the benefit of plenty of outside light, and also a window for supervision of the laboratory, without encroaching on any of the valuable ground floor space. The five-foot gallery, and the window sills in the thick walls, allow space for sundry small experiments to be going on at this level. The walls of the entire building should be very thick and substantial. Above, again, and close to the ceiling, is a mere assistants' gallery for suspending things and for getting to the top of any wall fixtures at that height (Fig. 9).

The upper floor may be regarded as mainly an optical laboratory, heliostat window on the south front opening into the principal dark room. It is suggested that this should be lightly partitioned off from the rest of the space so as to virtually leave several other rooms for working in; and there will be a supplementary dark room with a long wall bench on the north side for photographic purposes. Two ordinary doors into the optical room are shown in Fig. 10, and one pair of large doors for only occasional use, *e.g.*, for introducing large apparatus, and for letting in plenty of light for cleaning, &c.; but ordinarily to be closed and their chinks clothed over. The defect of such an optical room is that steadiness is difficult to secure, and yet for many optical experiments it is vital. A wall bench is not altogether convenient, and probably the best plan is to utilise the anvil principle, and support the bench on a great mass of iron bedded on indiarubber, or even (as Michelson does) floating on mercury. A pair of girders can always be made to support it independently of the floor. The optical room, as planned, is a mere expedient for securing local darkness, and its shape should be alterable

Digitized by Google

without much difficulty. If spectroscopic work is to be done, a rectangle and sliding bar for mounting a Rowland grating will, of course, be provided. Although sunlight is arranged for in connection with spectroscopy and other subjects where its use is essential, an arc lamp will also be provided for the numerous occasions when the sun is not visible.

### The Annexes.

Three of the angle rooms shown in Fig. 3, page 32 of last issue, will be passage-rooms, with a door at each end, and with plenty of side light in front. A long bench will run along under the window of each, and there can be a store-cupboard or chest of drawers at the back of each. The workshop can have a shaft driven from the electro-technical department; the store room is to contain chemicals and materials, wire, rod, tube, sheet, &c. The room labelled desk room will have to be mainly occupied by the entrance; and, in fact, if it can be made into both entrance and main staircase, its space will be exhausted.

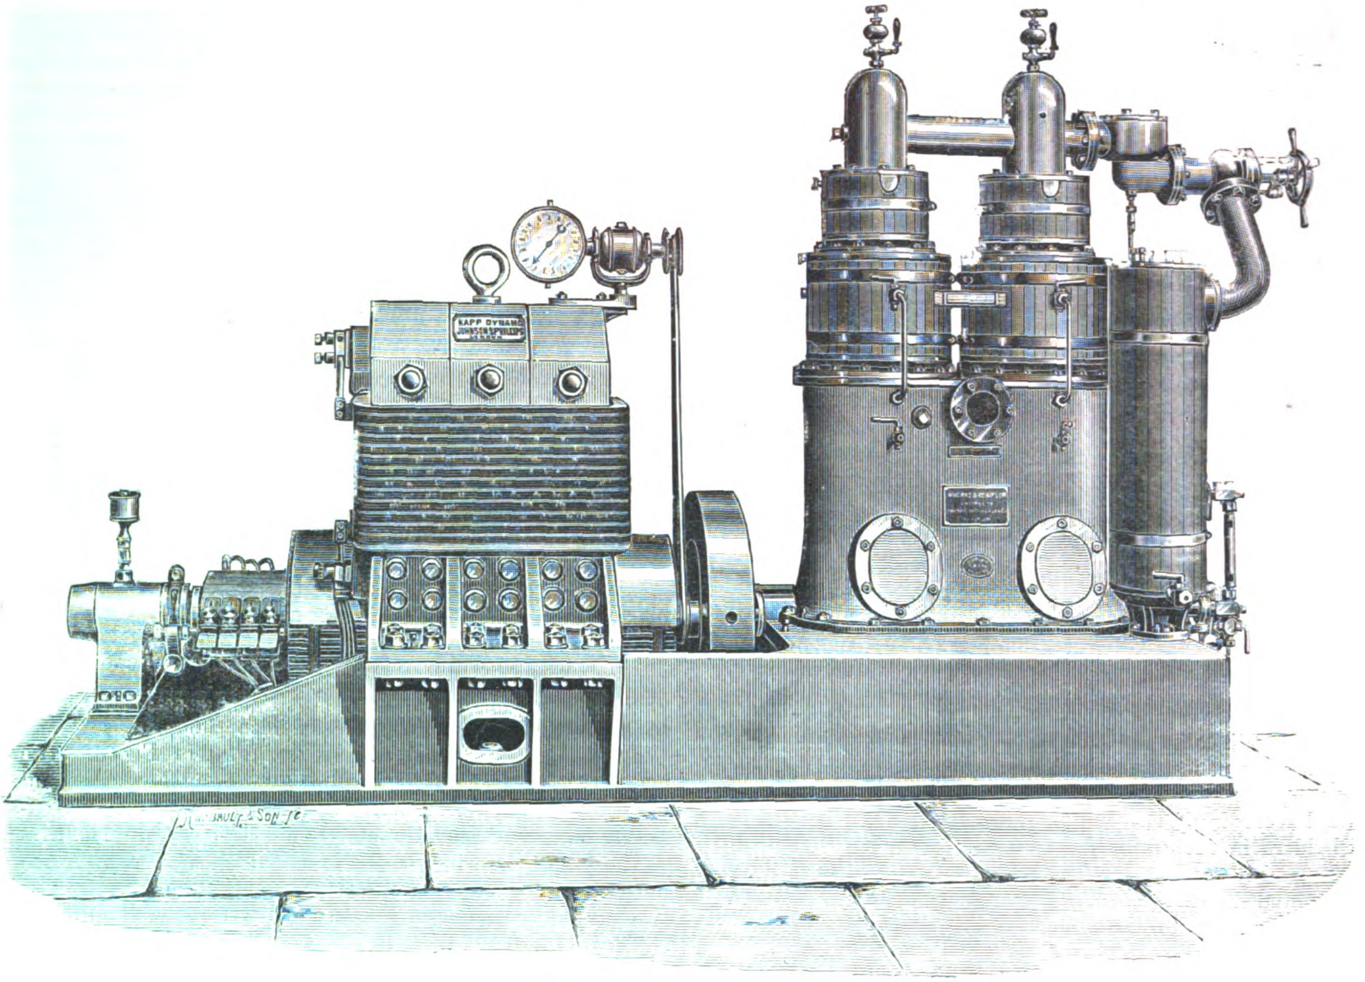
propose to leave the centre comparatively free from permanent fixtures. Beneath the centre of the dome there might be a railed-off pit leading down into the basement excavated under the central hall for uniform temperature operations.

### Basement.

As to the basement, it need not be lighted from the outer air at all. It should be well drained, whitewashed, and lighted by incandescent lamps, with a central arc light for making it more wholesome by occasional artificial sunlight.

### Astronomical Annexe.

A water tower with spiral staircase and clear central space has been spoken of as a suitable annexe. Another may very well be a small astronomical, magnetic, and meteorological observatory. A transit instrument, a clock, and an equatoreal with photographic and spectroscopic appliances, are the fittings suitable to the astronomical room; and the meteorological in-



Kapp-Willans Combination 50 kilowatts.

### The Central Hall.

The central space remains to be considered (Fig. 3). Doors will open out from it direct into each of the four main blocks, both on the ground and on the first floors, the first floor doors being connected by a wide gallery running all round it at the appropriate height. All round the walls, up to this gallery, will be the apparatus cases; and some pieces of large apparatus can stand about near the middle of the floor. Side lights at each corner begin at the height of the gallery and continue to the roof, which will probably be dome-shaped with a central lantern, and perhaps a small gallery round the lantern.

I did propose a central tower resting on columns and arches, but it may be better to keep the centre of the hall under the dome, free, and to erect a tower on a separate basis. A tower with a cistern for delivering water of a high uniform pressure is certainly useful, but it can very likely be obtained in connection with some adjacent building. The large space of the hall may be occasionally useful for experiment, and hence I should

struments may vary with the interest the professor or students take in the collection of data. A few inexpensive recording instruments would undoubtedly be instructive, and a student will commonly be found able and willing to look after them.

## TEST OF A WILLANS-KAPP COMBINATION.

For the lighting of the new Birmingham post-office there will be required three 50-kilowatt steam dynamos, and these sets have been supplied by Messrs. Willans and Robinson, who have obtained the dynamos from Messrs. Johnson & Phillips. As the engine-makers undertook the contract on a guaranteed consumption of steam per unit output, careful efficiency tests were made, and we give below a summary of the result.

The tests were carried out by passing the exhaust steam through a surface condenser, and weighing the water in the

Digitized by Google

manner described in Mr. Willans' classical paper on non-condensing steam-engine trials, *Proc.* Inst. C.E., Vol. xciii. The intervals of time given in the tests refer to the time taken to pass 100lb. of steam through the engine.

The dynamo is of the inverted type, as usual with this make. The armature is drum-wound, having a resistance of ·00527 ohms when warm. It contains 102 conductors, and a 51-part commutator. The resistance of the shunt is 17 ohms, and that of the main ·002 ohms. The volts are 112; the full current 456. The average indicated horse-power during the trial was 79·7, and the average output from the dynamo terminals was 447·2 amperes, at 112 volts pressure, making an average of 50·1 kilowatts, or 67·2 electrical horse-power. The mechanical efficiency of the set is therefore $\frac{67 \cdot 2}{79 \cdot 7} = 84 \cdot 25$ per cent. The consumption of steam per indicated horse-power is remarkably low.

## THE CENTRAL STATIONS OF THE METROPOLITAN ELECTRIC SUPPLY COMPANY.

BY DR. J. A. FLEMING, M.A.

*(Continued from page 9.)*

### THE MANCHESTER-SQUARE STATION.

This central electric supply station ranks next in order as regards degree of completeness after Sardinia-street. Like this last-named station, Manchester-square is an alternate transformer station, supplying distributed transformers placed on customers' premises by means of an underground system of primary conductors. The site on which the station stands was formerly a mews, and the first sod was turned on August 12, 1889, in the commencement of the station which has been erected on that place. The station may be described as capable, when in full operation, of an electrical output of a million watts. Hence it can supply an actual demand of 30,000 30-watt lamps, or is equal to supporting 50,000 such lamps wired. The station buildings are substantial brick buildings, which have been laid out with great skill to economise to the utmost the space at disposal.

The architectural work here, as well as that of the Sardinia-street station, was carried out by Mr. Robert Walker, F.R.I.B.A., and the engineering construction and design of the station has been done by Mr. J. E. H. Gordon. The dynamo room (Fig. 11) contains a set of 10 generating units, each composed of a 200 horse-power Willans triple expansion engine, working under a pressure of 200lb. of steam, combined on the same bed-plate with, and driving direct an Elwell-Parker alternator, having an output of 100 kilowatts.

The engines work at a speed of 355 revolutions per minute, and require 200lb. pressure of steam. The Elwell-Parker dynamo coupled to it has already been described in detail. (*See Electrician*, November 7, 1890, p. 15, Vol. 26.)

The dynamos at Manchester-square have 36 magnet poles on the revolving field magnets and 36 coils in the stationary armature, and, accordingly, there are about 12,000 alternations per minute in the resulting current, or a frequency of 100. The exciting current employed is a current of 28 to 34 amperes at a pressure of 100 volts. Each dynamo-bearing is provided with arrangements for circulating cold water through the hollow bearings in case of heating.

These dynamos furnish a current of 100 amperes at full load, under a pressure of 1,000 volts. To excite this battery of 10 alternators there are four exciters by Elwell-Parker, which are the ordinary shunt machines, each driven by a triple-expansion direct-coupled 60 horse-power Willans engine at a speed of 475 per minute. Two of these exciters are equal to doing the whole work of exciting the 10 alternators, and the fields of the alternators are, as usual, joined in parallel across the poles of the alternators. The arrangements for preventing the transmission of vibration from these engines and dynamos to the ground around are very perfect.

In preparing the foundations for each engine and dynamo, the ground was first excavated for a depth of 10 or 12ft., and a pit formed (*see* Fig. 12) in which was made a solid floor of

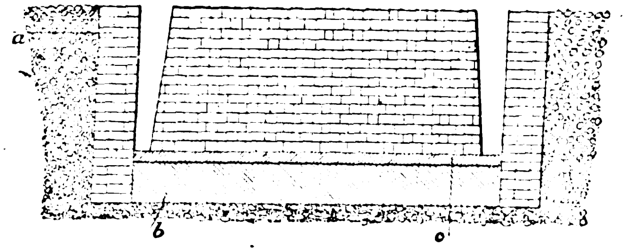

FIG. 12.—Manchester-square Station. Sectional view of the method of arranging the foundations so as to prevent vibration. *a* Retaining wall. *b* Sub-base. *c* Lead and felt.

concrete, and the sides built up. On this floor of concrete was laid a thick sheet of felt, and then one of lead, and on this was built up a block or table of brick. On this table are fixed and bolted the bed-plate of the engine and dynamo. It has been thus found possible to quench all vibration and prevent the communication of thump to the walls of the building and to the ground around. Entering the boiler-house (*see* Figs. 13 and 14) we find a battery of nine Babcock and Wilcox tubular boilers, each capable of evaporating 6,000lb. of water per hour. The consumption of all the engines when at full load will be 40,000lb. of water per hour. The arrangement by which large steam pipes are avoided is worth notice. Over each pair of boilers is a wide pipe or drum, and from each drum proceed steam pipes to two engines. All the drums are connected by equalising pipes, and as a result there is no steam pipe other than these drums which is larger than five inches in diameter, and the difficulties with large bends and joints thus avoided. The steam stop-valves which shut off each boiler are made with an outside screw thread, and a gunmetal female screw having a longitudinal slot through which oil can be squirted through the thread to prevent sticking. Each boiler has two feeds, one hot and one cold; so that if the hot feed fails from any cause the cold feed can be supplied. In blowing off the hot water from the boiler there is an arrangement by which cold water is mixed with the hot, so as to reduce it below a temperature of 212deg. when it enters the drains, or else the result of "blowing off" would be to fill all the drains of the surrounding neighbourhood with steam. A water tank is provided which will contain twelve hours' supply of water; but water can also be taken direct from the water mains. The coal

Digitized by Google

store has a capacity for 300 tons of coal, and the coal waggons arriving from the street shoots the coal directly down into the bunkers, which are adjacent to the stoke holes. Hard by the boilers are the feed-water heaters and the pumps. Two Owen's pumps are provided, either one of which will pump all the water required for the boilers. The exhaust steam from the engines passes into an exhaust pipe, which is 15in. in diameter at one end and widens to 25in. in diameter at the other. The large end opens into the chimney shaft. In order to prevent the exhaust steam from mixing with the smoke, this exhaust steam pipe is continued right up the chimney, being supported centrally right throughout its length by rings built into the brickwork, and which preserve it in position whilst permitting free expansion and contraction.

The shaft itself is 8ft. square inside at the bottom and 10ft. square inside at the top, and cased outside with white glazed bricks. The central exhaust steam-pipe is 26in. in diameter. The shaft is surmounted by a cast-iron chimney cap weighing 26 tons. This arrangement, which is due to Mr. Gordon, has the effect of abolishing the nuisance resulting from condensed steam and soot in the neighbourhood of the station. The exhaust steam not being contaminated with products of combustion dissolves quickly in the air. Adjoining the station is a house for the engineering staff, and when in full work the work will be arranged in three watches of eight hours each, and two watches on Sundays.

The whole of the station buildings are solidly built of brick, and lined with white glazed brick, like Sardinia-street.

*(To be continued.)*

## DRUM ARMATURE WINDING.

BY F. M. WEYMOUTH.

*(Continued from page 39.)*

Foucault currents may, however, be stopped by another method, also included in one of Mr. James Swinburne's patents, by which any twist in compound bars is rendered unnecessary. This applies in cases where it is possible to connect up the component parts of two bars of a coil, separately, and in such a manner that the tendency to these currents in each bar shall oppose that in the other. This is achieved in the manner indicated diagrammatically in Fig. 8. The pulley end of the armature is here shown, and one coil, each bar of which is composed of four strips laid edgeways. The strips of the one bar must then be connected to those in the other bar, separately, in the manner represented. The coil is, in fact, split into so many parallel planes. To understand this, we may imagine the coil to be revolving in the field in the direction indicated by the curved arrow. The upper pole-piece is north, and the lower south. The magnetic lines of force will thus be running from N to S, and will be most dense at the trailing horns, $a$ $a$. As rotation takes place it will be seen that both bars are approaching dense portions of the field, and the lines of force are running through both bars in the same direction, that is, toward S. Hence, as viewed from some point in the same plane as the coil, on one side, but outside the armature, the eddy current would circulate in each bar in the same direction; or, as seen from S, in the same direction as the hands of a watch. Thus, at the sides $w$ and $x$ of the two bars, the current would approach; while at the sides $y$ and $z$ it would recede, as indicated by the small arrows. The opposition of the two tendencies is at once obvious. The union of the strips in each bar at the commutator is, of course, of no consequence. The explanation can also be put in terms somewhat as follows:—Whereas the volts of $w$ $z$ may be greater or less than $y$ $x$, the sum of the volts of $y$ $z$ will about equal the sum of the volts of $w$ $x$. Hence no current will flow

In all cases, it may be mentioned, the bars, whether solid or compound, may be wound with cotton or silk tape and varnish for insulation. Solid bars are sometimes left bare, in sulated from one another by air gaps, and from the core by Willesden or Manilla paper, or other material, and varnish. They will, of course, be more liable to damage when left uncovered; but with compound bars the tape winding is, for the most part, necessary to maintain their shape. The varnish used is commonly shellac, though some makers use a speciality.

The heating of the bars should be still further obviated by efficient ventilation, a point we have already mentioned. The cores of large machines are usually made hollow. When revolving, the long lugs of the commutator, if there are any, act as centrifugal fan blades, and draw air through the hollow between the interior of the core and the spindle, and so assist to keep down the temperature. Some makers leave gaps in the core along its length, so that air from the interior may fly outwards, and help not

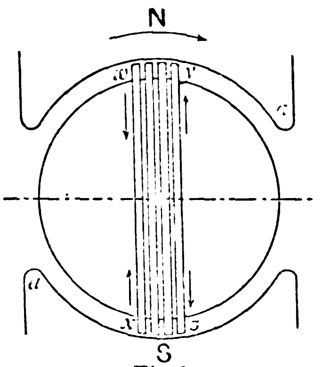

Fig. 8.

only to keep the core cool, but also the conductor bars on the periphery, and the pole-pieces. The bars will also draw air round after them, and so ventilate themselves. One of the advantages of the Hopkinson dynamo is thus here illustrated (Fig. 3, reproduced) since, owing to the fact that the horns stand away from the armature, air is more easily drawn down between it and the pole-pieces, and thus can be more effective in keeping the bars cool than when throttled and wire-drawn, as it were, by the closeness of the horns to the armature. The whole question of ventilation is not one to be passed over as inconsiderable. A phenomenon showing the effect of thorough ventilation may be observed when a dynamo stops after a run. The end winding, owing to its complete exposure, and revolving in a thorough draught, may feel cool to the hand at first; but presently it will become

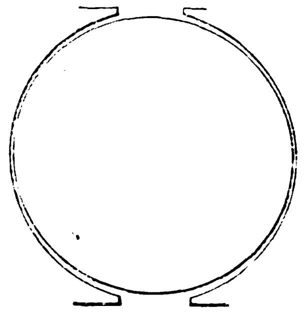

Fig. 3.

warm, owing to the heat from the interior portions of the winding and armature creeping out. This shows at once how great a difference ventilation makes. It may be remarked that not only does heat tend to generate in the conductors, but also in the iron core and the pole-pieces, especially in the trailing horns of the latter. Hence, when it is further borne in mind that a high temperature reduces the conductivity of the copper, the desirability of good ventilation becomes still more obvious. In fact, other things being equal, a greater output is obtainable from a well-ventilated machine than from one not ventilated. When a machine is run very hot, energy is wasted in the dissipation of the heat, as already pointed out in an earlier passage. Some makers supply auxiliary fans, or air propellers, especially for the purpose of creating a draught through a machine as it

Digitized by Google

runs. But, on the other hand, though thorough ventilation may keep the bars cool, there is yet, perhaps, some degree of falsity in the theory of this method of procedure. Heat is abstracted, and so energy lost, just as when the bars are allowed to heat—though it may be not so much, owing to the lesser resistance of the cool bars—beside the loss of power involved in driving a fan when one is used. Only by good ventilation the heat is drawn off more quickly, and the bars are kept cool, and at their normal conductivity. Hence, as already intimated, the size and therefore the first cost of a well-ventilated machine for a given output should be less than for one not ventilated. In some machines ventilation is further assisted by the magnets being formed of bars, with interstices between them, through which air may pass in and out of the field. A practical limit, however, to heating is the ability of the various materials used for insulation to endure a high temperature without perishing, or losing their insulating qualities. To this limit no doubt machines are sometimes run.

We may now proceed to describe some of the different methods in which heavy current windings are constructed, having special regard to the arrangement of the cross connections at the ends of the armature. It will be noted that a bar being the reverse of flexible, it cannot be dealt with as a mere wire. To have to bend it would be a matter of considerable trouble. Hence special means have to be adopted at the drum ends. These consist principally, though not in all cases, of separate lengths of metal. These are used to form a connection between the ends of two opposing bars forming the two sides of a

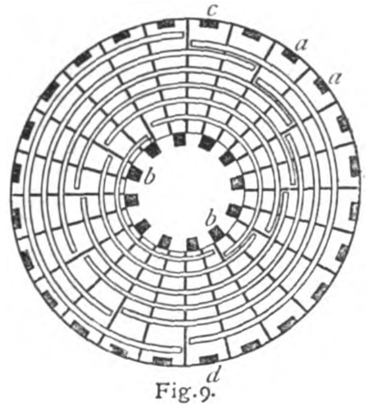

Fig. 9.

coil, and are united thereto by soldering, screwing, or both. As we have already pointed out, in armatures for heavy currents there is generally only one, or, at the most, but two turns per section. If high volts are required, the machine must be made larger, or the field stronger, or the speed increased, or all three. Matters are thus much simplified. It is, of course, not mechanically impossible to have more turns per section. But the extra complications involved, combined with many other disadvantages, render the idea in ordinary cases inadmissible.

Among the earliest of these methods brought out, is one patented by Edison. This is illustrated in Fig. 9, which shows an end view of an armature. The rectangular black dots *a a* are the parallel conductor bar ends. Each of these is let into and jointed to the periphery of a flat radial insulated metal plate, as shown. The radial plates of two bar ends desired to be connected up, such as *c* and *d*, are then united by a circular bar, as shown, jointed to each, but insulated from the other bars and plates. An electrical connection is thus carried round from one side to the other. It will be understood, in accordance with some of our preliminary remarks, that this sketch merely represents the principles of mechanical construction involved, and does not necessarily represent any one actual design. It is probable that the bars in Edison's early machines were connected up in the manner, though not in the order here shown. The parallel conductors here are bare, and, it will be observed, are a long way apart. This method is practicable indeed for a winding of a few sections only. Though each end of the armature is thus connected up, yet at the commutator end, which is here given, alternate radial plates are projected further inwards than the remainder, as shown in solid black at *b b*. These projections are each united to a commutator segment. Besides the drawback already intimated, this end winding has the further fault of not being symmetrical. Hence, a perfect balance and equality of resistance in the coils become often impossible. Some new arrangement thus becomes desirable.

*(To be continued.)*

## ON THE POTENTIAL DIFFERENCE BETWEEN TWO DILUTE SOLUTIONS IN CONTACT.*

BY MAX PLANCK.

The author, as well as W. Nernst, has already published a treatise on the calculation of the potential difference when the two fluids in contact are solutions of the same electrolyte at different degrees of concentration. He now shows how the same may be accomplished when two different solutions are used.

If $\phi$ denotes the potential, the constant $\epsilon$ the electrical charge of a monovalent + ion, the constant R the osmotic pressure of an ion occupying unit volume, $\xi$ a constant depending on the concentration and the mobility of the ions, then the required potential difference is—

$$\phi_2 - \phi_1 = \frac{R}{\epsilon} \log \xi.$$

When the calculation is based on the assumption of a complete dissociation, the calculated value will never correspond exactly with that observed. The limiting value which the potential difference approaches as the solutions are diluted may, however, be obtained. The calculated differences of potential are not independent of the time, for two solutions in contact are never in a state of equilibrium, diffusion taking place until the mixing is complete. For many solutions a constant value for the potential difference cannot be determined, though by a comparison of theory with practice a nearly constant difference may be arrived at.

The investigation of the general case when the ion is multivalent presents considerable difficulty, but it is found that if $n$ is the valency of the ion,

$$\phi_2 - \phi_1 = \frac{R}{n\epsilon} \log \xi$$

$n$ times less than when the ion is monovalent.

## MEETINGS OF SCIENTIFIC SOCIETIES, &c.

**FRIDAY, November 21st.**

THE JUNIOR ENGINEERING SOCIETY.

*8 p.m.* Presidential Address: "Electro-magnetic Mechanisms," by Prof. SILVANUS THOMPSON, D.Sc.

**MONDAY, November 24th.**

SOCIETY OF ARTS.

*8 p.m.* Cantor Lecture. 1. "Gaseous Illuminants," by Prof. VIVIAN B. LEWES.

**TUESDAY, November 25th.**

INSTITUTION OF CIVIL ENGINEERS.

*8 p.m.* Ordinary Meeting. Paper to be read: "The Vibratory Movements of Locomotives," by Prof. JOHN MILNE, F.R.S., and JOHN McDONALD.

ROYAL VICTORIA HALL.

*8.30 p.m.* Lecture: "The New Divisions of Africa," by HILLIARD ATTERIDGE.

**WEDNESDAY, November 26th.**

SOCIETY OF ARTS.

*8. p.m.* Ordinary Meeting. Paper to be read: "Physical Tests in Competitive Examinations," by FRANCIS GALTON, F.R.S.

**THURSDAY, November 27th.**

INSTITUTION OF ELECTRICAL ENGINEERS.

*8 p.m.* Ordinary General Meeting. Adjourned discussion on the following papers: "The Efficiency of Secondary Cells," "On the Chemistry of Secondary Cells," by Prof. W. E. AYRTON, F.R.S., C. G. LAMB, B.Sc., and E. W. SMITH.

**FRIDAY, November 28th.**

PHYSICAL SOCIETY.

*5 p.m.* Papers to be read: "Notes on Secondary Batteries," by DR. GLADSTONE and W. HIBBERT; "An Illustration of Ewing's Theorem of Induced Magnetism," by Prof. S. P. THOMPSON, D.Sc.

* Wiedemann's *Annalen*, Vol. XL., No. 8.

Digitized by Google

# The Electrician.

**Published every Friday, Price Fourpence; Post Free, Fourpence Halfpenny.**
**Editorial, Publishing, and Printing Offices:**
**SALISBURY COURT, FLEET ST., LONDON, E.C.**
*Telephone No. 2714. Telegrams:* "ELECTRICIAN NEWSPAPER, LONDON."

*All Letters relating to Subscriptions, Advertisements and other business matters should be addressed to the Publisher,* "THE ELECTRICIAN," *Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* "THE ELECTRICIAN" *Printing and Publishing Company, Limited, and be crossed* "Coutts and Co." *All other letters to be addressed to the Editor.*

*All letters intended for insertion in* "THE ELECTRICIAN," *or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever will be taken of anonymous communications.*

"THE ELECTRICIAN" *is published every Friday morning, in time for the morning mails. Subscribers should receive their copies by the first post on Friday morning.*

"THE ELECTRICIAN" *is on sale at the railway bookstalls throughout the Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices as above.*

*New Volumes of* "THE ELECTRICIAN" *commence in May and November.*

## SUBSCRIPTION RATES.

The rates for Subscriptions to "THE ELECTRICIAN" are as follows:—

| | 3 months. s. d. | 6 months. s. d. | 12 months. s. d. |
|---|---|---|---|
| For the United Kingdom | 5 0 | 10 0 | 19 6 |
| For Foreign Parts and Colonies:— Within Postal Union | 6 6 | 12 6 | 24 0 |
| Aden Borneo, Ceylon, China, India, Japan, Java, Labuan, Mozambique, New Caledonia, Persia, Philippine Islands, Siam, Transvaal, and Zanzibar | 7 6 | 14 6 | 28 0 |

## TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has by far the largest circulation of any English Electrical paper, and circulates all over the World.**

*Particulars relating to Advertisements will be promptly forwarded on application to the Offices as above,*

TRADE ADVERTISEMENTS *intended for the current issue must reach the Offices not later than First Post on Thursday morning. Renewals of expiring advertisement orders and alterations to standing adv rtisements should be in the Publisher's hands by Wednesday at latest. No alteration can be made in Wrapper advertisements after Wednesday evening.*

SMALL PREPAID ADVERTISEMENTS *(for Rates see page xvii.) are accepted up to 4 p.m. on Thursday.*

## TECHNICAL PRINTING.

"THE ELECTRICIAN" PRINTING AND PUBLISHING COMPANY (LIMITED) *inform Electricians, Electric Light Engineers, &c., that they make a specialty of Technical Printing, and have a large Staff thoroughly acquainted with Electro-Technology. They can, therefore, promise Accuracy and Despatch in the Printing of Electro-Technical Literature, &c.*

## "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. (Royal 8vo.)

*Early in each year is issued* "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. *The* DIRECTORY *was established in 1883, and the 1890 Edition consisted of about 850 pages of printed matter. The names and addresses of all persons engaged in the Electrical Industries at home and abroad may be relied upon as accurate. Useful Tables and Electrical Formulæ, and information specially compiled for this work are given, together with popularly-written Biographical Notices of the leading Electricians, Electrical Engineers, &c., accompanied in many cases by Portraits.*

*Orders for the 1890 issue should be forwarded* AT ONCE *to the Publishing Offices, Salisbury-court, Fleet-street, London, E.C.*

*The 1891 Edition is now preparing, and New Names, &c., can now be received.*

## ELECTRICAL BOOKS AND PUBLICATIONS.

*All Books, Newspapers, and other publications, dealing with Electrical and kindred subjects, can be ordered direct of* "THE ELECTRICIAN" *Printing and Publishing Company, who are proprietors of the well-known* "ELECTRICIAN" *Series of Standard Electrical Works, and are agents for all the leading publishing houses at home and abroad.*

## THE TRANSFER OF ENERGY BY THE ETHER.

IT is with some satisfaction that we find Dr. OLIVER LODGE reminding us in our correspondence columns that energy is a definite thing. In these days of fashionable philosophy and amateur metaphysics, there are many who would sweep away the very foundations of physical science. Writers who do not know the difference between power and force endeavour by their wordy artifices to deny the existence of matter, and give us instead incoherent rigmaroles about phenomena and concepts. If they would keep such discussions for themselves and their followers we should have no cause of complaint, but they thrust their theories before those who are concerned with the action of energy on matter; in fact, before engineers and students of physics. They deny, as mere assumptions, the continuity of energy, the continuity of space, and, indeed, of everything but their own arguments. The modern metaphysician finds no room for energy in his scheme of the foundation of things. Energy is asserted by some to be a mere product of force into distance, and force is only an inference from the motion itself, and is measured solely by the effect for which it is postulated as a cause. Even if it be allowed that force is the product of acceleration into mass, our idealists tell us that mass is but another name for inertia, and this is known and measured solely by the amount of force communicated to a given body in order to produce in it a determinate rate of acceleration. "There are only two Things going," says Mr. OLIVER HEAVISIDE in *The Electrician* Vol. XVIII., p. 211, "Matter and Energy. Nothing else is a thing at all; all the rest are Moonshine, considered as Things. The transfer of energy is a fact well known to all, even when we put the statement in such a form that the energy seems to lose its thinginess, by calling it the transfer of the power of doing work."

Digitized by Google

If matter and energy are the only things, what then is electricity? It has been hastily asserted that electricity is a form of energy or a mode of motion, and such statements are still to be found in elementary works; but a moment's reflection will show that the product of electricity into voltage gives power, or the rate at which energy is transferred. Is it then matter? No experiments have yet shown that electricity by itself and without connection with dielectrics exhibits the smallest indication of inertia, nor is it affected by gravitation. Professor KIMBALL's statement, at which Mr. JAMES JOHNSTONE rejoices, that electricity is a substance, is not sufficiently explicit; he immediately disclaims "the idea that like ordinary matter it has weight."

It is quite far enough to go, to allow, with Dr. OLIVER LODGE, that "whenever we perceive that a thing is produced in precisely equal and opposite amounts, so that what one body gains another loses, it is convenient and most simple to consider the thing not as generated in the one body and destroyed in the other, but as simply transferred. Electricity in this respect behaves just like a substance." But so much can be said for heat. The admirable thermodynamic work of CARNOT, the grandfather of the President of the French Republic, was founded entirely upon the assumption that heat behaved just like a substance; the error which he made was to go a step further, and, in accordance with the state of science of his day, to consider it *to be* a substance. This led him to imagine that the work of a steam engine is done at the expense of the fall of temperature, and that the energy of a certain quantity of heat in a hot body is greater than when it exists in a cooler body. We know now that the energy is the same, but it is less available. CARNOT's principle enables us to define efficiency; it has given us the second law of thermodynamics, and, as Sir WILLIAM THOMSON pointed out twenty-four years ago, it leads us to the most scientific way of defining temperature. If the two fluid or the one fluid language will enable us thus to state electrical theorems in a clear manner, we are in no way committed. And if, carefully distinguishing between the flow of electricity and the flow of electric energy, we agree to talk of electricity as material, since it behaves as a substance, great facility for expression and for the description of phenomena in simple terms is thus afforded us. But in doing this we need not go so far as Prof. KIMBALL, and demand a something which is not matter, but which may be called a substance. Modern science, while it attributes "thinginess" to matter and energy alone, fills all space with a *tertium quid*—the ether. The researches of HERTZ have been said to be the *experimenta crucis* which once and for all prove the actual existence of ether. But in the present state of the vortical theory of matter, and in view of a possible demand for a primordial fluid, it is more safe for the present to be content with the investigation of its properties, and to leave too definite ontological assertions for future philosophers. The property which the experiments of HERTZ have brought into such prominence—the propagation of electrical disturbances in time as well as in space—establishes the ether as the medium for the transfer of energy.

This brings us back, then, not necessarily to electricity—which is but a name for the agent which appears to underlie a certain group of phenomena, just as caloric was a very useful name, and was used to connote a similar agent which was supposed to appear and disappear by transference from one body to another—but to the transference of energy. If we could learn something about the mode of transfer, the nature of the strain to which the ether is subjected; or if strain be too definite a term, the displacement which is produced; or if we could find some good experimental grounds for the view that electricity is a disturbance which is measured quantitatively by the excess of the ether in a given space over the normal quantity, it would appear that we might ere long be able to drop the word electricity as indicating an entity, and retain it only in such indispensable terms as electrification and other derivatives.

The difficulty of introducing electricity as a substance, though not as matter, has caused some to think of the ether as being of a dual nature, which can be sheared into two constituents; others, following the one fluid theory, take ether simply as identical, as far as substance is concerned, with ether. We hope that before long the ether will be relieved of some of the many duties which are thrust upon it. How much more is to be expected of it? Its density is not allowed to exceed $10^{-18}$, and its rigidity is an equally inconceivable order. The most flimsy comet whisking round the sun feels it not, and if only we had a theory for gravitation we should probably exact another responsibility—the instantaneous transmission of stresses of enormous magnitude. It is said to be sometimes bound to the gross matter which it continuously pervades, and with some irony it is said to be otherwise free. By a convention rarely admitted with candour, its specific inductive capacity is unity, while at the same time the permeability is also said to be of unit value. As Dr. OLIVER LODGE remarks, both these conventions cannot be true; no one has the least right to suppose either true, and, in our opinion, no convention has ever given rise to such dire confusion, generating two discordant sets of units, and setting up the bewildering idea that an ohm is a velocity. Let us retain the ether as a patient overworked beast of burden, and let us determine its constants in absolute measure at our earliest possible convenience; but if the idea of transference of energy by its agency will answer the purpose, let us avoid splitting it up into one or more electricities, and let the very term electricity pass with epicycles, caloric, and many other once useful ideas, into the dignified repose of ancient history.

## MAGNETISM IN IRON AND OTHER METALS.*—XXXV.

BY PROF. J. A. EWING, F.R.S.

(*Continued from page 7.*)

§ 127.—**Effects of Applying Longitudinal Pull to Magnetised Iron.**— In the experiments described above the pull was applied before magnetisation began, and was then left constant. It remains to describe what is observed when the pull is varied while the magnetising force is kept constant. If there were no hysteresis, we should obtain in this way curves similar to those of Figs. 104 or 107. In consequence of hysteresis the changes of magnetism that are actually produced by changing the load, though maintaining a general similarity to these curves, differ from them in two important respects. In the first place, the *initial* effects which are observed when we first begin to change the stress are in general very great, and are to be distinguished from the effects obtained after a cycle of stress changes has been repeated once or twice. These initial effects of applying stress resemble those that are produced by vibration, although the process of loading may be conducted in such a way that no actual vibration takes place. They proceed, as the molecular theory to be discussed later indicates, from a condition of molecular instability; and they do not disappear when the stress is removed. Thus, when we begin to load for the first time an iron wire, to which a magnetising force has been applied, we find that the first loads are associated with an increase of magnetism, which may be so great as to increase the whole quantity ten-fold. Moreover, if a load has been hanging from

* All rights are reserved.

Digitized by Google

the wire while the magnetising force was being applied, we find that on beginning to remove it an increase of induced magnetism takes place. Again, if we are dealing with residual magnetism, the first effect of changing the load after the magnetising force has been removed (whether by way of increasing or decreasing the load) is in general to largely reduce the amount of the residue. It is only after applying and removing any load several times that the magnetic effects of the stress changes become cyclic; that is to say, after several repetitions of the operation, the magnetism will be found to alter from one to another of two definite values when the load is put on and when it is taken off. But even then the effects of hysteresis are manifest; for any intermediate value of the load is found to be associated with very different values of the magnetism during loading and during unloading. These features are well seen when we examine curves drawn to show the change

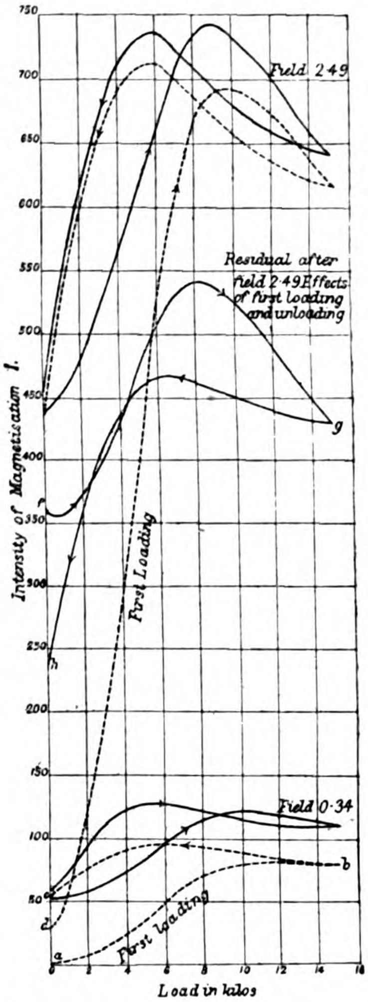

FIG. 108.—Effects of applying Pull to Magnetised Iron.

of magnetism in relation to the change of load, of which the following figures (108 and 109) are examples.* They refer to an iron wire, hardened by previous stretching beyond its elastic limit, of such a size that each kilo. of load corresponds to a stress of about 2·3 kilos. per sq. mm. The cycle of stress consisted in applying and removing 15 kilos.

Beginning at the bottom of Fig. 108, at the point marked *a*, we have the wire, free from any load and previously demagnetised by reversals, exposed to a magnetising force of 0·34 C.-G.-S. In this state there was very little magnetisation. Then loads were applied, and the effects of the first application and removal are shown by the dotted lines *a b c*. The full lines immediately above them show the effects of the *second* application and removal of load, by which time the magnetic changes had become nearly cyclic. It is clear that in the first loading we have to deal with a progressive augmentation of magnetism superposed on cyclic changes of the character shown by subsequent cycles of loading—that is to say, we have an initial effect superposed on the cyclic effect.

Next, the wire was demagnetised, and then a stronger field (2·49 C.-G.-S.) was applied, while there was no load. The effects of the first loading in this field were enormous; they

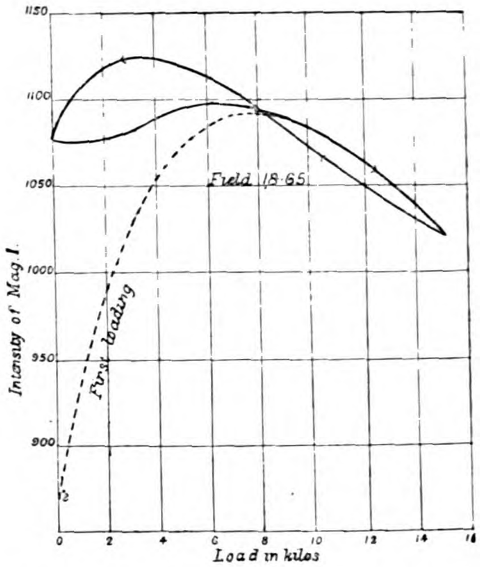

FIG. 109.—Effects of applying Pull to Strongly Magnetised Iron.

are shown by the dotted line which starts from the point *d* in the figure. Here, again, a repetition of the process of loading and unloading brought the magnetic changes into a nearly cyclic state, which is shown by the full lines at the top of the figure.

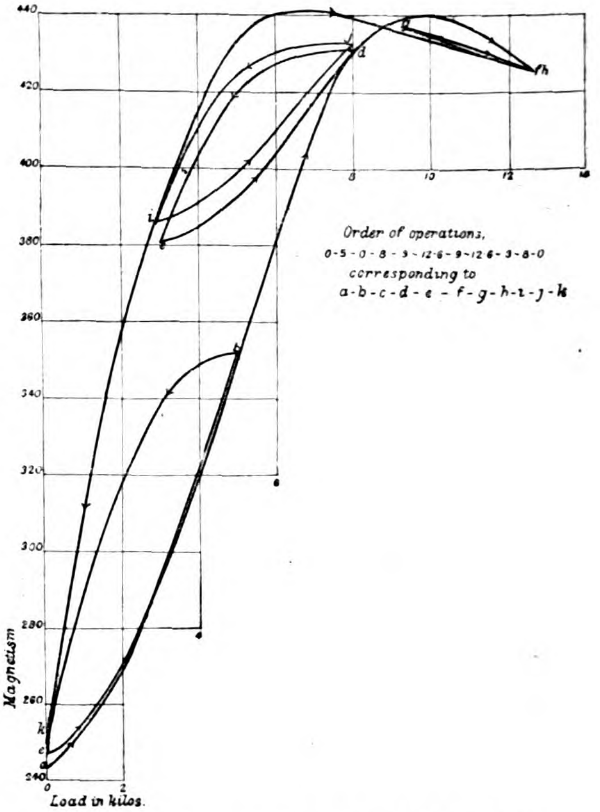

FIG. 110.—Effects of Pull on a Stretched Iron Wire.

Next, a stronger field still (18·65 C.-G.-S.) was applied (Fig. 109). The curve for first loading still shows a considerable permanent augmentation of magnetism; but a cyclic state is reached sooner than in weaker magnetic fields. In still stronger magnetic fields the curves become more and more

* *Phil. Trans.* 1885, plate 63, p. 603.

Digitized by Google

flattened down into a form in which the application of load causes a diminution of magnetism throughout.

Finally, to show how the residual magnetism is affected by change of stress, the residue left after applying a field of 2·49 and subjecting the wire to loads in that field, was made the subject of the experiment shown by the lines *f*, *g*, *h*, in Fig. 108. These curves show how (starting from the point *f*) the residual magnetism suffered changes due to loading and unloading, which may best be described as a progressive decrease of magnetism superposed upon cyclic changes of the same character as those which are shown in previous figures. If we repeat the cycles of load on a piece in which there is only residual magnetism, we find, in fact, cyclic changes of the same general kind as those that are found when a magnetising force is in action.

§ 128. **Hysteresis in the Effects of Stress.**—The hysteresis of magnetism with respect to changes of load, which is clearly exhibited by these curves, is static in character. That is to say, it does not depend on the time-rate at which loads are applied nor on the intervals which are allowed to elapse before readings of the magnetisation are taken. After any condition of load is reached, the magnetism does not change with the lapse of time, except possibly to a very insignificant extent.

During each loading, after a cyclic condition has been established, the magnetism is at first increased; but a maximum is passed as more load is added, and later additions of load reduce the magnetism. A similar maximum is seen during unloading; but owing to hysteresis the maximum comes at different loads in the two cases; each maximum is shifted, through hysteresis, to a later place in the operation than it would otherwise have. Another manifestation of hysteresis is seen in the easy gradient with which each curve begins, as the process of loading is changed to that of unloading, or *vice versâ*. In a weak field the initial gradient of each curve is so small that the curve appears to set out tangent to the line of loads.

Fig. 110 may be referred to in further illustration of the presence of hysteresis in changes of magnetism caused by changes of load.* It shows the effect of superposing on a principal cycle of stress changes several minor cycles, in each of which hysteresis is very apparent. The order in which the loads were applied was this:—0, 5, 0, 8, 3, 12·6, 9, 12·6, 3, 8, 0. The wire dealt with here had been hardened by stretching, and hung in a constant field the force of which was 0·34 C.-G.-S.

*(To be continued.)*

*Phil. Trans.*, 1885, p. 582.

## ELECTRO-MAGNETIC RADIATION.

BY PROF. A. L. KIMBALL, PH.D.

*(Concluded from page 35.)*

*The Experimental Study of Electro-Magnetic Waves.*

It has been known for many years that these electrical oscillations existed, but it remained for Prof. Hertz to show how the electrical waves given off from such a conductor might be detected and studied. The method of which he was the discoverer depends on what may be called *electrical resonance.*

It was discovered by Hertz that if two electrical conductors are taken of such sizes and shapes that the time of electrical oscillation in the one is the same as in the other, that when strong electrical vibrations are set up in one the other will also have an electric disturbance sympathetically excited. It is by making use of this fact that he was able to demonstrate the existence of electro magnetic waves and to measure wave lengths.

It will be well to examine briefly how some of the more important results have been demonstrated. Hertz apparatus involved what we shall call the vibrator and the resonator. In his earlier experiments the vibrator consisted of two sheets of tin, A and B (Fig. 3), about a foot square, provided with knobs and separated by a small gap C. These plates were connected one with each pole of a powerful induction coil D. The resonator (Fig. 4) was simply a hoop of wire, in which there was left a gap, the terminals being made of little knobs, whose distance apart could be accurately adjusted by means of a micrometer screw.

When the induction coil was made to act, the plates A B where charged and discharged by sparks across the gap C.

The resonator E was made of such a size and shape that the period of electrical vibrations in it might be the same as in the vibrator, and the adjustment was finally made by changing the sizes of the knobs until the best effect was obtained.

But how can it be established that these effects are really due to waves, and how can the wave lengths be measured? The characteristic phenomenon by which the existence of waves is recognised is *interference.* That is, two waves may come together in such a way that one shall exactly neutralise the effect of the other, or by slightly changing their relative *phases* they may re-inforce each other. In case of water waves, for example, if two sets of waves are coming from separate points, there will be certain points where the crests of the two sets of waves will arrive simultaneously; these will be points of great disturbance; there will be other points where the crests of one set of waves will arrive at the same instant as the troughs of the other sets of waves; these will be points of minimum distribution, for one set of waves will largely or entirely neutralise the effect of the other set. These are what are known as *interference* effects, and it is by these interference effects in case of light that it is known to be a wave motion, and that the wave lengths are measured. It at once became a point of peculiar interest to discover whether such effects could not be demonstrated in case of electro-magnetic waves, and the discovery of these interference effects by Hertz established beyond all question the existence of electro-magnetic waves.

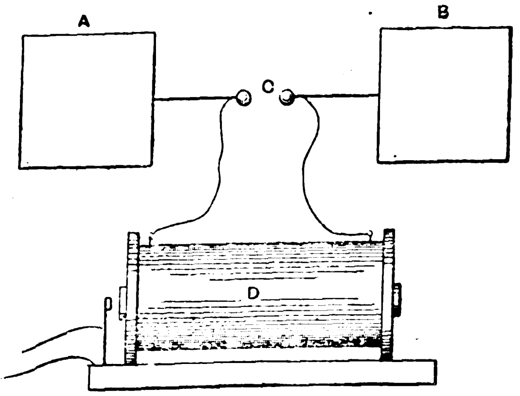

Fig. 3.

In one experiment the vibrator sending out the waves was placed directly opposite, and at a distance of 40 feet from a wall which had been covered with sheet metal, and so was a good reflector. The reflected waves meeting those coming directly from the vibrator gave rise to interference, producing what are analogous to the nodes and loops set up when a sounding tuning fork is held in front of a reflecting wall.

In an electro-magnetic wave there are two elements to be considered—the electric currents and the magnetic inductors; and, thinking of it again, according to the mechanical analogy previously discussed, it is evident that the one will be a maximum when the other is a minimum.

In an ordinary sound wave the points of rarefaction and condensation are places when the air particles are moving with greatest *velocity*, while midway between them where the density of the air in the wave is normal, the *displacement* of the air particles from their equilibrium positions is greatest. When a sound wave is reflected from a hard surface, a node or point of rest of the air particles is found at the surface, another such node or point of rest is found at a distance of one-half a wave length from the reflecting surface by the interference of the advancing with the reflected wave, and between these two nodes there is what is called a loop or a point where the motion of the air particles is a maximum, and so on, we find nodes and loops succeeding each other in regular order, the distance between two successive nodes being half the length of the wave. But while the nodes are places of minimum motion they are

Digitized by Google

points where the change in density of the air is a maximum. So in the case of electro-magnetic waves when reflected from the surface of a conductor; at that surface the changes in magnetic induction will be a maximum, while the changes in the electric displacement will be a minimum; a half wave length from the conducting surface this will be changed; there will be no magnetic induction, while the changes in the electric displacement will be a maximum, and so on alternately, thus constituting electro-magnetic nodes and loops. In Fig. 5 the state of things near the reflecting wall in Hertz's experiment is represented, the distances being indicated in metres on the scale at the bottom of the diagram. The vibrator sending out the wave is supposed to be off at the right, with its axis vertical and parallel to the paper, so that in the waves represented electric displacements are up and down in the plane of the paper, while the magnetic lines of induction are perpendicular to the paper.

If at some point on the line from the vibrator perpendicular to the reflecting surface the circle of wire used as a resonator is placed with its plane parallel to the reflecting surface, and with the spark gap neither at the top nor bottom, but at one side, the effect observed will be wholly independent of the magnetic lines of force, since none of them will go through the circle, and since in that position the electric displacements are the same at all points of the circle, the effect will depend only on the intensity of the changes in the displacements; the circle may therefore be used in this way to compare the intensities of the displacement currents at different points. On performing the experiment in this way Hertz found that there was scarcely any sparking when the resonator was near the wall, but that it increased in intensity on carrying it away, reaching a maximum at B, then diminished again to a minimum at C, and finally

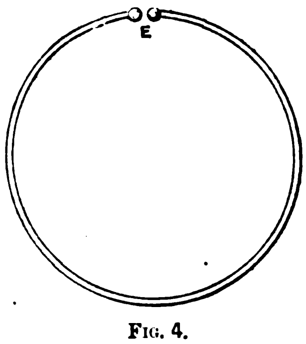

Fig. 4.

increased as the circle was moved toward D; the periodicity could not be traced farther, owing to the preponderance of the direct waves as the vibrator was approached more nearly. This experiment indicated that the electric displacement was a minimum at the wall, a maximum at the distance B, again a minimum at C, &c., indicating that the distance from B to C was one-quarter of a wave length. In this way the length of the wave was found to be 9·3 metres. It will be noticed that in the diagram (Fig. 5) the distance from B to the wall is rather less than from B to C. This is due to the fact that the point at the reflecting surface is not exactly a node, owing to the surface not being a perfect conductor, so that there were slight displacement currents even close to the reflector. That this is the true explanation of the observed phenomena was further shown by determining in a similar way the points where the changes in the magnetic intensity were a maximum. For this purpose the resonator or circle is held with its plane vertical and perpendicular to the reflecting plane, or just as represented in positions I., II., III., IV. in the diagram, except that the spark gap was at the top or bottom instead of at the side, as in the case indicated. In this position of the circle the electric displacements, being up and down, have scarcely any influence in causing sparking to take place at the gap; but the magnetic lines of force, being at right angles to the coil, pass through it, and hence changes in the magnetic induction at the point where the circle is placed, give rise to electromotive forces acting around the circle and causing sparks to leap the gap. In this position, therefore, the greatest sparking will be observed where the changes in magnetic induction are greatest. Observation showed marked sparking at the reflecting surface, which fell rapidly to zero as B was approached, increased again to a maximum at C, then diminished to a second minimum at D, and finally increased as the circle was moved beyond D nearer to the vibrator, the disturbing influence of the neighbourhood of the vibrator being felt as before. These two experiments gave independently the length of the waves sent out by the vibrator, and in accordance with theory showed that the maxima for changes in magnetic induction lay between the points where the electric displacement currents were a maximum. The diagram illustrates this point, vertical distances between the dotted lines representing the intensity of the change in magnetic induction, and the same for the solid lines, giving the intensities of the displacement currents.

By these experiments the fact that we are here dealing with a wave motion may be regarded as established and the length of the wave determined. The time of vibration of the electric currents in the vibrator was calculated by Hertz from the form and dimensions of the apparatus as about 2·8 hundred-millionths of a second. If the wave length is divided by the period of vibration the velocity of the wave is obtained. Taking the figures given, we obtain thus 332,000,000 metres per second as the velocity of the wave; but the velocity of light is 300,000,000 metres per second, and the difference between the two may be readily due to an error in the calculated period of vibration of the apparatus, that being a quantity which cannot be accurately computed. It may be concluded, then, that so far as the velocity of the wave is determined by these experiments, they point to the same velocity as that of light.

It is well known that electro-magnetic disturbances are communicated from the sun to the earth, as shown in the magnetic

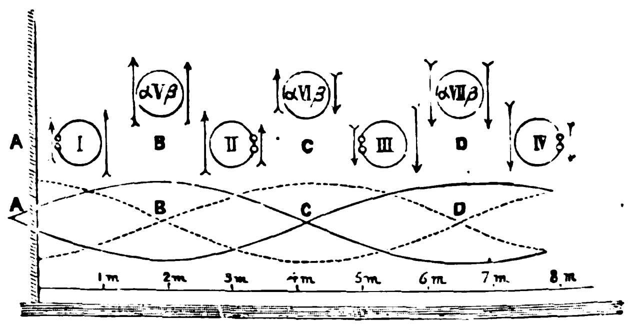

Fig. 5.

disturbances accompanying great sun spot activity. This indicates that some medium fills the region between the earth and sun which is capable of communicating these electro-magnetic disturbances, but the medium known as the luminiferous ether, or simply the ether, fills all space as far as light can travel, and it is more rational to suppose this to be the medium also by which electric disturbances are communicated rather than to imagine another medium, at least unless this supposition can be disproved. But the fact that electro-magnetic waves are propagated with the same velocity as light waves is almost proof positive of the correctness of the view, since the velocity of a wave depends on the properties of the medium in which it exists, as has been already noted.

Electro-magnetic waves are, then, ether waves; but light waves are also ether waves. What, then, is the difference between a wave of light and an electro-magnetic wave such as is sent out from a Hertz vibrator? The difference is believed to be solely one of wave length, or of the period of the vibration, only those electro-magnetic waves affecting the eye as light whose wave length is between one-thirty-thousandth of an inch and one-seventy-thousandth.

*Conclusion.*

The modern theory of electricity is characterised by its view of the importance of the dielectric medium. In looking at a dynamo supplying energy to a motor the current is no longer regarded as a fluid simply forced around the circuit and having no relation to the surrounding space; but not only is the flow of current always accompanied by magnetic whirls and electric

Digitized by Google

stresses in the medium, but Prof. Poynting has shown that it is through the medium rather than through the wire that the energy is to be regarded as communicated. Thus at the dynamo energy is being given to the medium in setting up lines of magnetic force, and these spreading outwards in every direction gradually grow smaller, forming circles around the wire, and finally collapse into it, their energy being transformed into heat in the wire at the point where they disappear. This spreading out of energetic whirls in the medium, and their collapse into the wire where the energy is dissipated as heat, continues as long as the current flows. The wire, from this point of view, does not convey the energy, but simply directs the energy which the medium receives at the dynamo, so that it shall be spent at the desired point, being simply a sort of leading string for the energy in providing a place where it may be dissipated in the form of heat, or, as in the motor, in mechanical work. Electrical science may, therefore, almost be called the science of the ether, for when a magnet attracts a weight it is forced up by the stresses in the ether, and even when a street car moves by a motor it is these same strains and stresses in the ether originating at the dynamo which urge it along.

## SOME PRACTICAL METHODS FOR THE DETERMINATION OF INDUCTIVE RESISTANCES AND SELF-INDUCTION OF ALTERNATE-CURRENT INSTRUMENTS.*

BY CHAS. STEINMETZ.

Since the system of distributing electricity by alternating currents and transformers has found such manifold applications, terms formerly rarely used, such as self-induction, retardation, &c., have come into general use, and determinations of inductive resistances, and of coefficients of self-inductions of measuring instruments, will soon be carried on as everyday work.

Now, the instrument mostly used for the determination of self-induction and mutual induction is the ballistic galvanometer. But not only is this instrument generally too delicate for the unstable floor of an electric factory, but it has the disadvantage that its readings very often cannot directly be applied for the alternating currents of our machines.

The following more simple method for the determination of self-induction requires no other apparatus but an alternate-current voltmeter and ammeter—instruments available in any electric factory which is building alternate-current apparatus.

### A. Inductive Resistances.

To find the coefficient of self-induction of an inductive resistance (induction coil, transformer, &c.), I connect the inductive resistance to be determined in series with an alternating-current ammeter, and connect an alternate-current voltmeter in shunt to ammeter and inductive resistance.

Let R be the true electric resistance of the induction coil, and L its unknown coefficient of self-induction. Let $r$ and $l$ be the corresponding quantities relating to the ammeter.

Now, in sending an alternating current of known number of periods through this circuit, the current in the inductive resistance, read by the ammeter, may $= c$, and the difference of potential around inductive resistance and ammeter, read by the voltmeter in the shunt circuit, may $= p$.

Then the E.M.F., or potential, lost in overcoming the whole electric resistance of this branch circuit is—

$$e+E=(r+R)c. \quad \dots\dots \quad (1)$$

The whole E.M.F. of self-induction in this circuit is—

$$e^1+E^1=\frac{2\pi(l+L)}{T}c, \quad \dots\dots \quad (2)$$

where T is the time in seconds of one full period.

The impressed E.M.F., $p$, measured by the voltmeter, is the resultant of these two E.M.F.'s: $(e+E)$ and $(e^1+E^1)$. But $e+E$ has the same phase as the current $c$. $e^1+E^1$ lags behind $c$ by a difference of phase of exactly 90°.

Therefore, the resulting E.M.F. of $e+E$ and $e^1+E^1$ is found by the law of the parallelogram of E.M.F.'s as the hypothenuse of a rectangular triangle, of which the sides are $e+E$ and $e^1+E^1$.

* Abstract from an article in the *Electrical Engineer* of New York.

Therefore $$p=\sqrt{(e+E)^2+(e^1+E^1)^2}.$$

Or, substituting (1) and (2) we get the coefficient of self-induction of the inductive resistance—

$$L=\frac{T}{2\pi}\sqrt{\left(\frac{p}{c}\right)^2-(r+R)^2}-l. \quad \dots\dots \quad (3)$$

When we can assume the approximation $r=0$, we get—

$$L=\frac{T}{2\pi}\sqrt{\left(\frac{p}{c}\right)^2-R^2}-l. \quad \dots\dots \quad (4)$$

And when $R=0$, too,

$$L=\frac{Tp}{2\pi c}-l. \quad \dots\dots \quad (5)$$

And, if the self-induction $l$ of the ammeter can be neglected also—

$$L=\frac{Tp}{2\pi c}, \quad \dots\dots \quad (6)$$

which formula will be found sufficiently exact in very many cases.

Therefore, for approximate determination of the coefficient of self-induction, if $r$ and R are small, it is not necessary to know the electric resistance at all, and the current in the alternating circuit is almost entirely independent of the electric resistance, depending only on the impressed E.M.F. and the self-induction. For the determination of small electric resistances, I consider as the most reliable method, to send a continuous current through them and measure current strength and potential.

Let the continuous current in the circuit of ammeter and inductive resistance $=c_0$, the potential difference $=p_0$. Then we have—

$$p_0=(r+R)c_0; \quad \dots\dots \quad (7)$$

and by substituting this we get—

$$L=\frac{T}{2\pi}\sqrt{\left(\frac{p}{c}\right)^2-\left(\frac{p_0}{c_0}\right)^2}-l; \quad \dots\dots \quad (8)$$

or, if $r$ and $l$ can be neglected—

$$L=\frac{T}{2\pi}\sqrt{\left(\frac{p}{c}\right)^2-\left(\frac{p_0}{c_0}\right)^2}. \quad \dots\dots \quad (9)$$

This method has the feature of eliminating the resistance of the connecting wires, which, when the main resistance is small, cannot well be neglected.

As an instance I shall give the following test made by me some time ago on an inductive resistance. The resistance of the ammeter, an electro-dynamometer, with one turn as the movable circuit, was—

$$r=\cdot01 \text{ ohm};$$

its coefficient of self-induction—

$$l=\cdot000066 \text{ henry}.$$

The alternate current was produced by a small Westinghouse dynamo, giving 100 complete periods per second; therefore—

$$T=\cdot01 \text{ second}.$$

The continuous current was derived from a storage battery. The readings were:—

Continuous current—

$c_0=26{\cdot}40$ amperes; potential, $p_0=1{\cdot}742$ volt.

Alternate current—

$c=16{\cdot}62$ amperes; potential, $p=31{\cdot}01$ volts.

Therefore, the coefficient of self-induction, by formula (8)—

$$L=\cdot002902 \text{ henry},$$

and the electric resistance—

$$r+R=\frac{p_0}{c_0}=\cdot066 \text{ ohm};$$

and since $r=\cdot01$ ohm,

therefore, $R=\cdot056$ ohm.

Formula (4) gives $L=\cdot002904$ henry,

and (5) $L=\cdot002970$ henry.

In considering that the exactness of the test was limited by the inconstancy of the speed of the alternator, which, driven by an ordinary steam engine, fluctuated by more than 2 per cent., the approximate figure ·002904 henry, and even ·002970 henry, could be considered exact enough for most purposes.

### B. Measuring Instruments.

The static electrometer is considered the best instrument for measuring alternate current potentials. But, unfortunately, this delicate instrument is hardly adapted for practical use in the factory. The calorimetric instruments, as, for instance, the Cardew voltmeter, can also be highly recommended. But for direct measurement of the strength of alternating currents, hardly any other instrument can be relied upon but the electro-dynamometer, although its self-induction has to be considered sometimes. If we make the necessary corrections for self-induction, the electro-dynamometer can also very well be used as a voltmeter. The main condition for all electro-dynamic alternate-current instruments is, that their magnetic field always corresponds to the instantaneous strength of the current, so that for the same current the magnetism is the same, no matter whether the current is increasing or decreasing. This condition excludes all instruments containing iron, and also such instruments in which eddy-currents can be set up. Seeing the difficulty of securing practical alternate current instruments without self-induction, we have to find methods to determine the amount of this self-induction and the corrections necessitated by it. In measuring the strength of currents only, by the electro-dynamometer-ammeter, self-induction has no influence; but its determination becomes necessary where these readings are to be used for calculations of resistance, self-induction, power, and so on.

To determine the self-induction of an alternate-current instrument, a very reliable way is, after having tested the instrument by continuous currents, so that it can be used as an ammeter, giving the effective current flowing through it, to proceed as follows:—

1. Connect it, together with an additional non-inductive resistance, if necessary, in parallel with a current-indicator. For this any instrument can be used, which for the same effective current always gives the same reading, no matter whether this reading is right or wrong; therefore, most of the non-polarised continuous-current instruments can be used.

Let the electric resistance of the instrument proper $= r$.

Let the additional non-inductive resistance $= r_0$.

Let the alternating current flowing through the instrument, and read by it as an ammeter $= c_1$.

Let the reading of the current-indicator in the shunt-circuit $= v$.

2. Connect the instrument $r$ with its additional resistance $r_0$ in series with a non-inductive resistance R and in parallel with the same current indicator, and vary the alternating current so that the current indicator gives again the same reading $v$, thereby showing that the shunt-current, and therefore the potential-difference at the terminals of the branch-circuit containing the instrument, is again the same as in connection (1).

Then let the alternate current flowing through the instrument $= c_2$.

Now, in the first connection (1), the electromotive force consumed by overcoming the electric resistance, is—

$$e_1 = (r + r_0)\, c_1.$$

The E.M.F. due to self-induction—

$$e_1' = \frac{2\pi L}{T} c_1;$$

where L is the coefficient of self-induction of the instrument, and T the period. Therefore, the resulting or impressed E.M.F., according to the parallelogram law, is—

$$\sqrt{e_1^2 + {e_1'}^2} = c_1 \sqrt{(r + r_0)^2 + \frac{4\pi^2 X^2}{T^2}}.$$

In the same way, the resulting or impressed E.M.F., with the second connection (2) is found:—

$$\sqrt{e_2^2 + {e_2'}^2} = c_2 \sqrt{(r + r_0 + R)^2 + \frac{4\pi^2 X^2}{T^2}};$$

and these expressions are equal, since the shunt currents are the same, and we therefore get—

$$L = \frac{T}{2\pi} \sqrt{\frac{c_2^2 (r + r_0 + R)^2 - c_1^2 (r + r_0)^2}{c_1^2 - c_2^2}}; \quad . \quad . \quad (10)$$

and the shifting of phase, that is, the difference of phase $\omega$ between current and terminal pressure of the instrument is given by the equation—

$$\tan \omega = \sqrt{\frac{c_2^2 \left(1 + \frac{r_0 + R}{r}\right)^2 - c_1^2 \left(1 + \frac{r_0}{r}\right)^2}{c_1^2 - c_2^2}} \quad . \quad (11)$$

Now, in making several readings with continuous currents, we can eliminate the resistances $r_0$ and R. In connecting the instrument in a continuous-current circuit in series with $r_0$, with R, and with both $r_0$ + R and varying the current so that the current indicator in the shunt gives the same reading $v_0$; or, interpolating for this reading $v_0$, we may get the three currents—

$c_3$ through $r_0$ and the instrument $r$.

$c_4$ through $r_0$ + R and the instrument $r$.

$c_5$ through R and the instrument $r$.

Then we have—

$$c_3 (r + r_0) = c_4 (r + r_0 + R) = c_5 (r + R); \quad . \quad . \quad (12)$$

and we can deduce—

$$L = \frac{rT}{2\pi} \cdot \frac{c_5}{c_4 c_5 + c_3 c_4 - c_3 c_5} \sqrt{\frac{c_2^2 c_3^2 - c_1^2 c_4^2}{c_1^2 - c_2^2}}, \quad . \quad (13)$$

with a similar modification for tan $\omega$.

Now, when we can attribute to the additional resistance $r_0$ a particular value, for instance make it = 0, or = R, we shall save one of the continuous current readings and the formulæ become simpler. Thus, if $r_0 = 0$, we have $c_5 = c_4$.

$$L = \frac{rT}{2\pi c_4} \sqrt{\frac{c_2^2 c_3^2 - c_1^2 c_4^2}{c_1^2 - c_2^2}} \quad . \quad . \quad . \quad . \quad (14)$$

$$\tan \omega = \frac{1}{c_4} \sqrt{\frac{c_2^2 c_3^2 - c_1^2 c_4^2}{c_1^2 - c_2^2}} \quad . \quad . \quad . \quad . \quad (15)$$

While, if $r_0 = R$, we have $c_5 = c_3$, and the formulæ become similarly modified.

An example will show the application of this method. In a low-reading voltmeter of the electro-dynamometer type the resistance was—

$$r = 19{\cdot}68 \text{ ohms.}$$

$$r_0 = 0;$$

no additional resistance being used. It was found—

For alternating currents—

$c_1 = {\cdot}3478$ ampere; $c_2 = {\cdot}1697$ ampere.

For continuous currents—

$c_3 = {\cdot}3734$ ampere; $c_4 = {\cdot}1628$ ampere.

Therefore, by formulas (14) and (15):—

$$L = {\cdot}03543 \text{ henry,}$$

the coefficient of self-induction of this voltmeter; and the angle shifting of phase—

$$\text{Angle } \omega = 29{\cdot}5 \text{ degrees.}$$

$$R = \frac{r(c_3 - c_4)}{c_4} = 25{\cdot}45 \text{ ohms};$$

and $$\frac{1 - \cos \omega}{\cos \omega} = {\cdot}149 = 14{\cdot}9 \text{ per cent.}$$

Therefore for such alternating currents of 100 full periods per second the readings of this instrument have to be increased by 14·9 per cent. to get the correct voltage. The correction for any other number of periods can easily be calculated. This method is open to the objection of inaccuracy upon the assumption that the alternate currents are true sine-waves. But in looking farther into the matter, we shall often find this to be of advantage for practical purposes. Because, if we do not want to know the absolutely exact value of the coefficient of self-induction for scientific purposes, but want to use the instruments to measure alternating dynamo currents and the behaviour of inductive resistances toward them, then the figures obtained in this way hold good for the same kind of dynamo currents, and allow us to assume them again as true sine-waves in the calculations of electric machinery. Besides, in most of the altenators built to-day, the deviation of current from the sine-wave is rather small.

## TESTING THE CENTRALITY OF CABLE CORES.*

BY PAUL LE GOAZIOU.

The following little apparatus has been devised to test the centrality of the copper conductors of submarine and subterranean cables.

The draw-plate, as I call it, consists of four copper rods, 1, 2, 3, and 4 (Fig. 1), arranged on a wooden or ebonite disc B B', which is pierced with a hole at the centre. These rods are 10 to 15 centimetres long, and can slide backwards and forwards on the disc so that their ends can be made to press lightly against the insulation of the cable to be tested. In Fig. 2 we have a longitudinal section of the apparatus, from which it can be seen that a sort of funnel is screwed on to the back of the disc B B', in order to guide the cable

* From *La Lumière Électrique*.

Digitized by Google

through the telephonic draw-plate. The calibre of this funnel is, of course, different for different sizes of cables. Water is sometimes poured into this funnel to prevent heating, and if it is of great importance to reduce friction to minimum the whole apparatus is placed in a vertical position.

Two differential telephones, T T′ (Fig. 1), are connected as shown, that is to say, the front and back portions of rod 1 are connected to

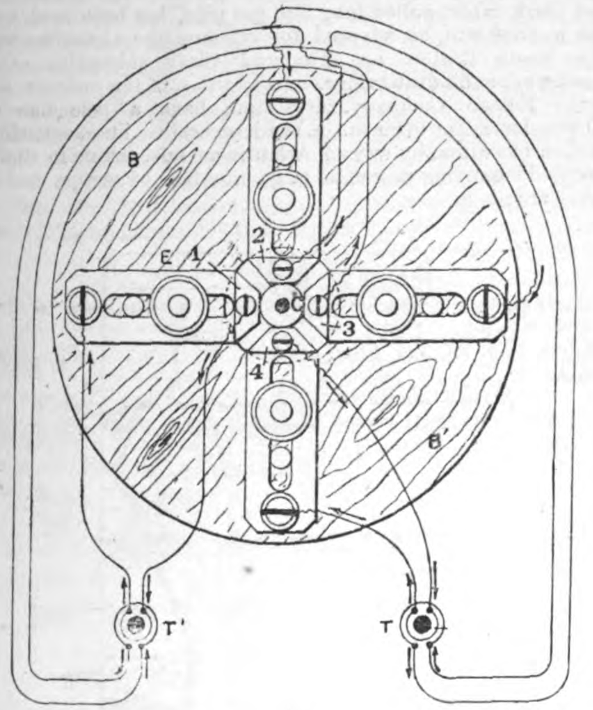

FIG. 1.—Cross-section of Apparatus (two-thirds actual size).

one part of the telephone T′, while the front and back portions of the opposite rod 3, are connected to the other coil of the same telephone, and so on. While the cable is being passed through the telephonic draw-plate, a weak intermittent current is sent through its conductor. This intermittent current traversing the conductor of the cable induces Foucault currents in the copper rods. If the centrality of the cable conductor is perfect, it is obvious that the telephones will remain silent, but if the centrality of the conductor

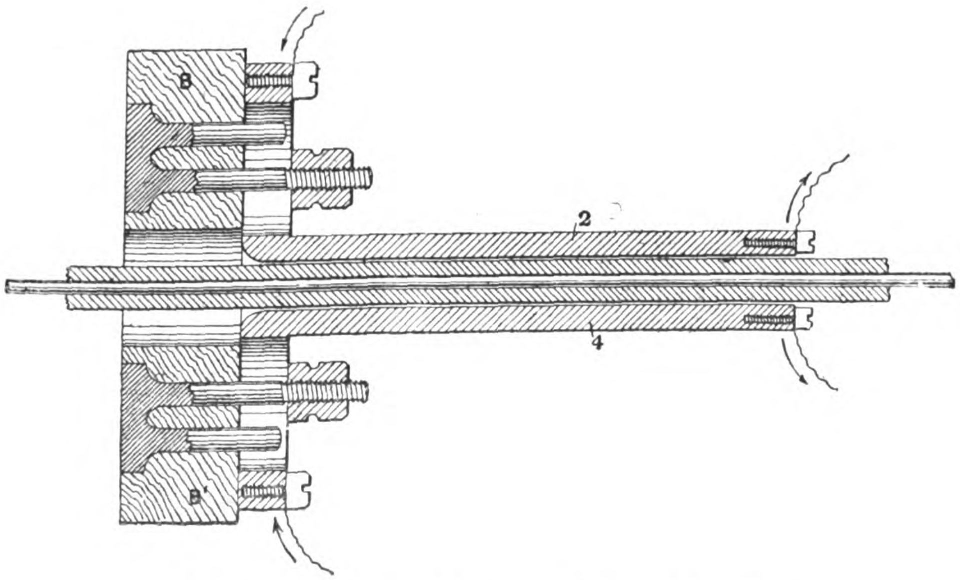

FIG. 2.—Longitudinal Section of Apparatus (two-thirds of actual size.

is imperfect, the rod nearest it has a stronger current generated in it than the opposite rod, consequently the particular telephone, the coils of which are connected differentially to these two rods, will be affected.

Fig. 3 shows clearly the different cases that may arise. If the conductor is well in the centre, as at *a*, nothing happens; if it is near rod 1, as at *b*, the coil connected to this rod is strongly affected acting on the telephone T. If the conductor is in the position shown at *c*, both the telephones T and T′ will speak. In this last case the position of the conductor can be determined by lightly turning the disc B B′ until the eccentric conductor has arrived at a position similar to that which it holds in *b*. In order to determine which rod the conductor is nearest to, it is only necessary to switch in a high resistance into the circuit of one of the differential coils. If the noise in the telephone is weakened, the cable-conductor obviously lies nearest the rod into whose circuit the high resistance has been switched, and *vice versâ*. The exact degree of eccentricity of the conductor can be determined by sliding back the rod nearest to the cable conductor. When the telephone is silent the two rods are obviously at the same distance from the inducing wire. The distance traversed by the rod is then read off on a millimetre scale, which is engraved on the disc, and half this distance gives the distance of the conductor from the centre of the cable. This postulates that the dielectric constants of air and gutta-percha are practically the same for currents of this order.

In carrying out this test in practice, the operator in charge has the telephonic receivers fixed to his ears in the ordinary manner, and whenever he hears a noise in either of the telephones he marks the cable as it passes through the draw-plate with a dab of paint, and the cable is subsequently re-examined more carefully at these marked points.

In order to avoid the necessity of constructing two differential telephones, two ordinary telephones may be used. In this case the connections are as follows:—The front ends of rods 1 and 3 (Fig. 1) are joined to the terminals of the telephone, and their other ends are joined together, rods 2 and 4 being similarly connected up. The same result is obtained by the circulation of opposite currents in the same coil as by the use of two distinct windings. This arrangement has, however, the inconvenience that if one wishes

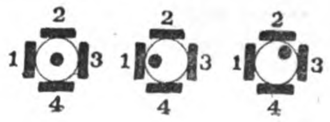

FIG. 3.

to determine exactly the degree of eccentricity of the cable conductor it is necessary to slide back one of the rods, which is a less rapid operation than merely switching in and out an additional resistance, as is done in the case of the differential telephones.

This little apparatus should prove of some use in testing the centrality of conductors of large cables. Up to the present the method employed somewhat resembles that of Alexander the Great when confronted with the Gordian knot; that is to say, the electrician charged with taking over the cable whenever he thinks the conductor is out of truth chops the cable in two; if his suspicions prove correct, the contractor pays for repairs; if the electrician is wrong, the purchaser pays.

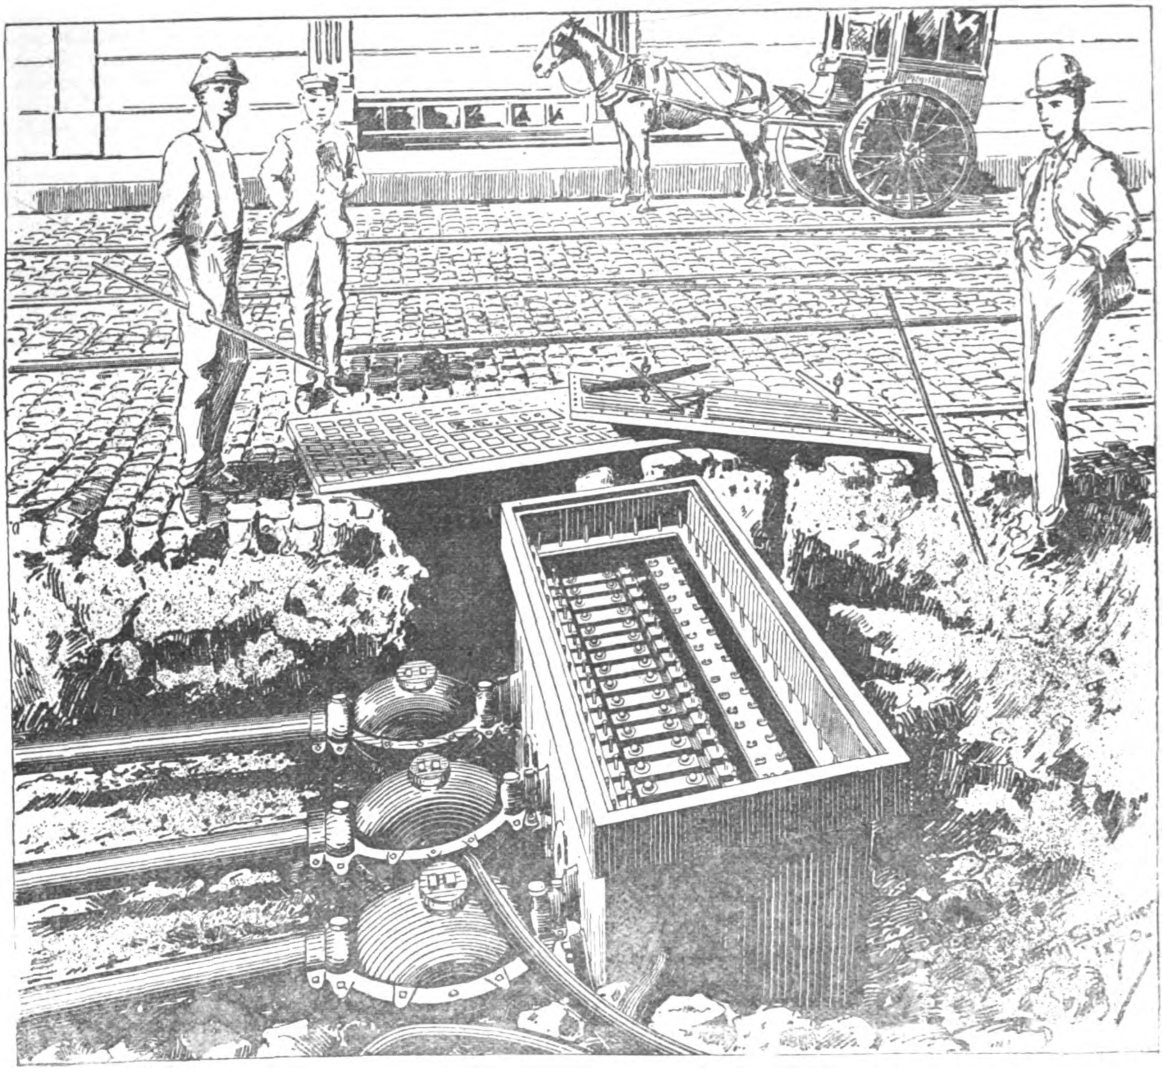
## EDISON UNDERGROUND WORK IN BOSTON.*

BY A. C. SHAW.

The Edison system of underground feeders and mains is well enough known, but there are constantly improvements being made; and I show in the accompanying engraving a special feeder junction box, which has been designed and put into operation by the Edison Electric Illuminating Company, of Boston. The object of the junction box is to subdivide long feeders into sections of not over 1,000ft. in length, so that, should any trouble ever develop on such a feeder, it is not necessary to dig up the streets, and cut the feeder in two, three, four, or six parts to locate the trouble. As lighting extends, the feeders become longer, and in Boston there are some feeders as long as 6,000ft., and it becomes a serious matter to locate possible trouble. The junction box, as shown, is designed for six feeders, and is made of cast iron, the inside dimensions being 3ft. wide, 5ft. long, and 3½ft. deep. There is a projecting ledge in the found interesting. From the two stations, one in Head-place and the other on Hawkins-street, there are now running some 32,000 incandescent lights, about 1,400 horse-power in motor service, and about 50 Ward arc lights. The extreme distance covered by the underground system is about two miles. In all, there are some 40 miles of underground feeders and mains, the longest feeder being 6,000ft., several of 3,750ft., and the shortest being about 250ft. The largest feeder used is 750,000 circular mils (·587 sq. in.) solid copper. In crossing the bridges over the railway on Shawmut-avenue, specially prepared Clark cable, pulled into 3in. gas pipe, has been used, and a similar method will be adopted for crossing the Concord-street bridge to South Boston, an armoured Clark submarine cable being used under the drawbridge. In addition to the underground work, the Edison Company, of Boston, have a pole line of 100,000 circular mils (·0785 sq. in.) with several tie lines, extending from station to station, by way of Atlantic-avenue, taking in all the wharves, and supplying power to large numbers of motors used in these busy thoroughfares.



Edison Underground Mains in Boston.—Special Feeder Junction Box.

ordinary manner with screw studs for fastening down the inside cover, which is made water tight by means of a rubber gasket, and melted wax, in the usual way. As will be seen, there is provision for pressure wires, the small terminals on the right hand side being for that purpose, while copper strips shown on the left hand side serve to make connections for the feeder. By use of this box, when two or more feeders run through it, when a feeder is faulty it is not necessary to cut out the whole feeder while repairing; the faulty section only is cut out, and flexible insulated cable connections can be used from the upper nuts for short-circuiting the faulty part. The pressure wires are then connected from the junction box instead of the catch boxes at the end of the feeders, and the remainder of the two feeders are used like large mains, the potential being kept constant at the junction box instead of at the catch box. The Edison Company, of Boston, have now six in use, and provision is being made for putting them on all long feeders, different sizes of boxes being used according to the number of feeders in the locality. A few figures regarding the Edison work in Boston may be

* From the *Electrical Engineer* of New York.

## THE ELECTRO-MAGNET.*

BY PROFESSOR SILVANUS P. THOMPSON

*(Continued from page 50.)*

EFFECT OF SHAPE OF SECTION.

So far as the carrying capacity for magnetic lines is concerned, one shape of section of cores is as good as another; square or rectangular is as good as round if containing equal sectional area. But there are two other reasons, both of which tell in favour of round cores. First, the leakage of magnetic lines, from core to core, is, for equal mean distances apart, proportional to the surface of the core; and the round core has less surface than square or rectangular of equal section. All edges and corners, moreover, promote leakage. Secondly, the quantity of copper wire that is required for each

* A series of four Cantor Lectures delivered before the Society of Arts, January—February, 1890.

Digitized by Google

turn will be less for round cores than for cores any other shape, for of all geometrical figures of equal area the circle is the one of the least periphery.

### Effect of Distance between Poles.

Another matter that Du Moncel experimented upon, and Dub and Nicklès likewise, was the distance between the poles. Dub considered that it made no difference how far the poles were apart. Nicklès had a special arrangement made which permitted him to move the two upright cores or limbs, 9 centimetres high, to and fro on a solid bench or yoke of iron. His armature was 30 centimetres long. Using very weak currents he found the effect best when the shortest distance between the poles was 3 centimetres; with a stronger current 12 centimetres; and with his strongest current nearly 30 centimetres. I think leakage must have a deal to do with these results. Du Moncel tried various experiments to elucidate this matter, and so did Prof. Hughes, in an important but too little-known research which came out in the "Annales Télégraphiques" in the year 1862.

### Researches of Prof. Hughes.

His object was to find out the best form of electro-magnet, the best distance between the poles, and the best form of armature for the rapid work required in Hughes's printing telegraphs. One word about Hughes's magnets. This diagram (Fig. 51) shows the form of the well-known Hughes's electro-magnet. I feel almost ashamed to say those words "well known," because, although on the Continent everybody knows what you mean by a Hughes's electromagnet, in England scarcely anyone knows what you mean. Englishmen do not even know that Prof. Hughes has invented a special form of electro-magnet. Hughes's special form is this:—A permanent steel magnet, generally a compound one, having soft iron pole-pieces, and a couple of coils on the pole pieces only. As I have to speak of Hughes's special contrivance amongst the mechanisms that will occupy our attention only now refer to this magnet in one particular. If you wish a magnet to work rapidly, you will secure the most rapid action not when the coils are distributed all along, but when they are heaped up near, not necessarily entirely on the poles. Hughes made a number of researches to find out what the right length and thickness of these pole-pieces should be. It was found an advantage not to use too thin pole-pieces, otherwise the magnetism from the permanent magnet did not pass through the iron without considerable reluctance, being choked by insufficiency of section; also not to use too thick pieces, otherwise they presented too much surface for leakage across from one to the other. Eventually a particular length was settled upon, in proportion about six times the diameter, or rather longer. In the further researches that Hughes made he used a magnet of shorter form, not shown here, more like those employed in relays, and with an armature from 2 to 3 millimetres thick, 1 centimetre wide, and 5 centimetres long. The poles were turned over at the top towards one another. Hughes tried whether there was any advantage in making those poles approach one another, and whether there was any advantage in having as long an armature as 5 centimetres. He tried all different kinds, and plotted out the results of observations in curves, which could be compared and studied. His object was to ascertain the conditions which would give the strongest pull, not with a steady current but with such currents as were required for operating his printing telegraph instruments; currents which lasted but one to twenty-hundredths of a second.

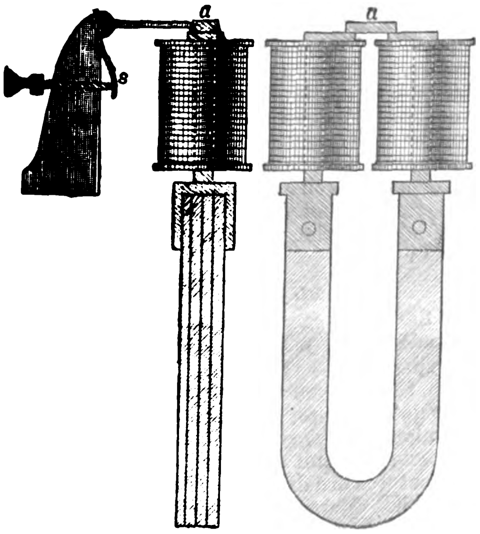


Fig. 51.—Hughes's Electro-magnet.

He found it was decidedly an advantage to shorten the length of the armature, so that it did not protrude far over the poles. In fact he got a sufficient magnetic circuit to secure all the attractive power that he needed, without allowing as much chance of leakage as there would have been had the armature extended a longer distance over the poles. He also tried various forms of armature having very various cross-sections.

### Position and Form of Armature.

In one of Du Moncel's Papers on electro-magnets* you will also find a discussion on armatures, and the best forms for working in different positions. Amongst other things in Du Moncel you will find this paradox; that whereas using a horse-shoe magnet with flat poles, and a flat piece of soft iron for armature, it sticks on far tighter when put on edgeways; on the other, if you are going to work at a distance, across air, the attraction is far greater when it is set flatways. I explained the advantage of narrowing the surfaces of contact by the law of traction, $B^2$ coming in. Why should we have for an action at a distance the greater advantage from placing the armature flatway to the poles? It is simply that you thereby reduce the reluctance offered by the air gap, to the flow of the magnetic lines. Du Moncel also tried the difference between round armatures and flat ones, and found that a cylindrical armature was only attracted about half as strongly as a prismatic armatures having the same surface when at the same distance. Let us examine this fact in the light of the magnetic circuit. The poles are flat. You have at a certain distance away a round armature; there is a certain distance between its nearest side and the polar surfaces. If you have at the same distance away a flat armature having the same surface, and, therefore, about the same tendency to leak, why do you get a greater pull in this case than in that? I think it is clear that if they are at the same distance away, giving the same range of motion, there is a greater magnetic reluctance in the case of the round armature, although there is the same periphery, because though the nearest part of the surface is at the prescribed distance, the rest of the under surface is farther away; so that the gain found in substituting an armature with a flat surface is a gain resulting from the diminution in the resistance offered by the air gap.

### Pole-pieces on Horse-shoe Magnets.

Another of Du Moncel's researches† relates to the effect of polar projections or shoes—movable pole-pieces, if you like—upon a horse-shoe electro-magnet. The core of this magnet was of round iron 4 centimetres in diameter, and the parallel limbs were 10 centimetres long and 6 centimetres apart. The shoes consisted of two flat pieces of iron slotted out at one end, so that they could be slid along over the poles and brought nearer together. The attraction exerted on a flat armature across air gaps 2 millimetres thick was measured by counterpoising. Exciting this electro-magnet with a certain battery, it was found that the attraction was greatest when the shoes were pushed to about 15 millimetres, or about ¼ of the inter-polar distance, apart. The numbers were as follows:—

| Distance between shoes, Millimetres. | Attraction, in grammes. |
|---|---|
| 2 | 900 |
| 10 | 1,012 |
| 15 | 1,025 |
| 25 | 965 |
| 40 | 890 |
| 60 | 550 |

With a stronger battery the magnet without shoes had an attraction of 885 grammes, but with the shoes 15 millimetres apart, 1,195 grammes. When one only pole was employed, the attraction, which was 88 grammes without a shoe, was *diminished* by adding a shoe to 39 grammes!

### Contrast between Electro-magnets and Permanent Magnets.

Now I want particularly to ask you to guard against the idea that all these results obtained from electro-magnets are equally applicable to permanent magnets of steel; they are not, for this simple reason. With an electro-magnet, when you put the armature near, and make the magnetic circuit better, you not only get more magnetic lines going through that armature, but you get more magnetic lines going through the whole of the iron. You get more magnetic lines round the bend when you put an armature on to the poles, because you have a magnetic circuit of less reluctance, with the same external magnetising power in the coils acting around it. Therefore, in that case, you will have a greater magnetic flux all the way round. The data obtained with the electro-magnet (Fig. 42), with the exploring coil, c, on the bend of the core, when the armature was in contact, and when it was removed, are most significant. When the armature was present it multiplied the total magnetic flow tenfold for weak currents, and nearly threefold for strong currents. But with a steel horse-shoe,

* *La Lumière Electrique*, Vol. II.
† *La Lumière Electrique*, Vol. IV., p. 129.

Digitized by Google

magnetised once for all, the magnetic lines that flow around the bend of the steel are a fixed quantity, and however much you diminish the reluctance of the magnetic circuit you do not create or evoke any more. When the armature is away the magnetic lines arch across, not at the ends of the horse-shoe only, but from its flanks; the whole of the magnetic lines leaking somehow across the space. When you have put the armature on, these lines, instead of arching out into space as freely as they did, pass for the most part along the steel limbs and through the iron armature. You may still have a considerable amount of leakage, but you have not made one line more go through the bent part. You have absolutely the same number going through the bend with the armature off as with the armature on. You do not add to the total number by reducing the magnetic reluctance, because you are not working under the influence of a constantly impressed magnetising force. By putting the armature on to a steel horse-shoe magnet you only *collect* the magnetic lines, you do not *multiply* them. This is not a matter of conjecture. A group of my students have been making experiments in the following way. They took this large steel horse-shoe magnet (Fig. 52), the length of which from end to end through the steel is 42½in. A light narrow frame was constructed so that it could be slipped on over the magnet, and on it were wound thirty turns of fine wire, to serve as an exploring coil. The ends of this coil were carried to a distant part of the laboratory, and connected to a sensitive ballistic galvanometer. The mode of experimenting is as follows:—The coil is slipped on over the magnet (or over its armature) to any desired position. The armature of the magnet is placed gently upon the poles, and time enough is allowed to elapse for the galvanometer needle to settle to zero. The armature is then suddenly detached. The first swing measures the change, due to removing the armature, in the number of magnetic lines that pass through the coil in the particular position.

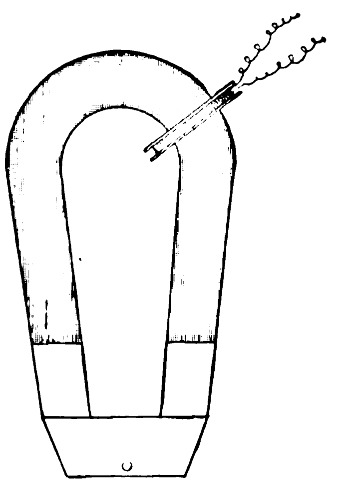

Fig. 52.—Experiment with Permanent Magnet.

I will roughly repeat the experiment before you: the spot of light on the screen is reflected from my galvanometer at the far end of the table. I place the exploring coil just over the pole, and slide on the armature; then close the galvanometer circuit. Now I detach the armature, and you observe the large swing. I shift the exploring coil, right up to the bend; replace the armature; wait until the spot of light is brought to rest at the zero of the scale. Now, on detaching the armature, the movement of the spot of light is quite imperceptible. In our careful laboratory experiments, the effect was noticed inch by inch all along the magnet. The effect when the exploring coil was over the bend was not as great as 1-3000th part of the effect when the coil was hard up to the pole. We are therefore justified in saying that the number of magnetic lines in a permanently magnetised steel horse-shoe magnet is not altered by the presence or absence of the armature.

You will have noticed that I always put on the armature gently. It does not do to slam on the armature; every time you do so, you knock some of the so-called permanent magnetism out of it. But you may pull off the armature as suddenly as you like. It does the magnet good rather than harm. There is a popular superstition that you ought never to pull off the keeper of a magnet suddenly. On investigation, it is found that the facts are just the other way. You may pull off the keeper as suddenly as you like; but you should never slam it on.

From these experimental results I pass to the special design of electro-magnets for special purposes.

### Electro-magnets for Maximum Traction.

These have already been dealt with in the preceding lecture; the characteristic feature of all the forms suitable for traction being the compact magnetic circuit.

Several times it has been proposed to increase the power of electro-magnets by constructing them with intermediate masses of iron between the central core and the outside, between the layers of windings. All these constructions are founded on fallacies. Such iron is far better placed either right inside the coils or right outside them, so that it may properly constitute a part of the magnetic circuit. The constructions known as Camacho's and Cance's, and one patented by Mr. S. A. Varley in 1877, belonging to this delusive order of ideas, are now entirely obsolete.

Another construction which is periodically brought forward as a novelty is the use of iron windings of wire or strip in place of copper winding. The lower electric conductivity of iron, as compared with copper, makes such a construction wasteful of exciting power. To apply equal magnetising power by means of an iron coil implies the expenditure of about six times as many watts as need be expended if the coil is of copper.

### Electro-magnets for Maximum Range of Attraction.

We have already laid down the principle which will enable us to design electro-magnets to act at a distance. We want our magnet to project, as it were, its force across the greatest length of air gap. Clearly, then, such a magnet must have a very large magnetising power, with many ampere-turns upon it, to be able to make the required number of magnetic lines pass across the air resistance. Also it is clear that the poles must not be too close together for its work, otherwise the magnetic lines at one pole will be likely to curl round and take short cuts to the other pole. There must be a wider width between the poles than is desirable in electro-magnets for traction.

### Electro-magnets of Minimum Weight.

In designing an apparatus to put on board a boat or a balloon, where weight is a consideration of primary importance, there is again a difference. There are three things that come into play—iron, copper, and electric current. The current weighs nothing, therefore if you are going to sacrifice everything else to weight, you may have comparatively little iron, but you must have enough copper to be able to carry the electric current; and under such circumstances you must not mind heating your wires nearly red hot to pass the biggest possible current. Provide as little copper as you conveniently can, sacrificing economy in that case to the attainment of your object; but, of course, you must use fire-proof material, such as asbestos, for insulating, instead of cotton or silk.

### A Useful Guiding Principle.

In all cases of design there is one leading principle which will be found of great assistance, namely, that a magnet always tends so to act as though it tried to diminish the length of its magnetic circuit. It tries to grow more compact. This is the reverse of that which holds good with an electric current. The electric circuit always tries to enlarge itself, so as to enclose as much space as possible, but the magnetic circuit always tries to make itself as compact as possible. Armatures are drawn in as near as can be, to close up the magnetic circuit. Many two-pole electro-magnets show a tendency to bend together when the current is turned on. One form in particular, which was devised by Ruhmkorff for the purpose of repeating Faraday's celebrated experiment on the magnetic rotation of polarised light, is liable to this defect. Indeed, this form of electro-magnet is often designed very badly, the yoke being too thin, both mechanically and magnetically, for the purpose which it has to fulfil.

Here is a small electric bell, constructed by Wagener of Wiesbaden, the construction of which illustrates this principle. The electro-magnet, a horse-shoe, lies horizontally; its poles are provided with protruding curved pins of brass. Through the armature are drilled two holes, so that it can be hung upon the two brass pins; and when so hung up it touches the ends of the iron cores just at one edge, being held from more perfect contact by a spring. There is no complete gap, therefore, in the magnetic circuit. When the current comes and applies a magnetising power, it finds the magnetic circuit already complete in the sense that there are no absolute gaps. But the circuit can be bettered by tilting the armature to bring it flat against the polar ends, that being indeed the mode of motion. This is a most reliable and sensitive pattern of bell.

*Electro-magnetic Pop-gun.*—Here is another curious illustration of the tendency to complete the magnetic circuit. Here is a tubular electro-magnet (Fig. 53), consisting of a small bobbin, the core of which is an iron tube about 2in. long. There is nothing very unusual about it; it will stick on, as you see, to pieces of iron when the current is turned on. It clearly is an ordinary electro-magnet in that respect. Now suppose I take a little round rod of iron about an inch long, and put it into the end of the tube, what will happen when I turn on my current? In this apparatus as it stands, the magnetic circuit consists of a short length of iron, and then all the rest is air. The magnetic circuit will try to complete itself, not by shortening the iron, but by *lengthening* it; by pushing the piece of iron out so as to afford more surface for leakage.

Digitized by Google

That is exactly what happens; for, as you see, when I turn on the current the little piece of iron shoots out and drops down. You see that little piece of iron shoot out with considerable force. It becomes a sort of magnetic pop-gun. This is an experiment which has been twice discovered. I found it first described by Count Du Moncel, in the pages of *La Lumière Electrique*, under the name of the "pistolet électro-magnétique;" and Mr. Shelford Bidwell invented it independently. I am indebted to him for the use of this apparatus. He gave an account of it to the Physical Society in 1885, but the reporter missed it, I suppose, as there is no record in the Society's proceedings.

### Electro-magnets for use with Alternating Currents.

When you are designing electro-magnets for use with alternating currents, it is necessary to make a change in one respect, namely, you must so laminate the iron that internal eddy-currents shall not occur; indeed, for all rapid acting electro-magnetic apparatus it is a good rule that the iron must not be solid. It is not usual with telegraphic instruments to laminate them by making up the core of bundles of iron plates or wires, but they are often made with tubular cores, that is to say, the cylindrical iron core is drilled with a hole down the middle, and the tube so formed is slit with a saw-cut to prevent the circulation of currents in the stance of the tube. Now when electro-magnets are to be employed with rapidly alternating currents, such as are used for electric lighting, the frequency of the alternations being usually about 100 periods per second, slitting the cores is insufficient to guard against eddy-currents; nothing short of completely laminating the cores is a satisfactory remedy. I have here, thanks to the Brush Electric Engineering Company, an electro-magnet of the special form that is used in the Brush arc lamp when required for the purpose of working in an alternating-current circuit. It has two bobbins that are screwed up against the top of an iron box at the head of the lamp. The

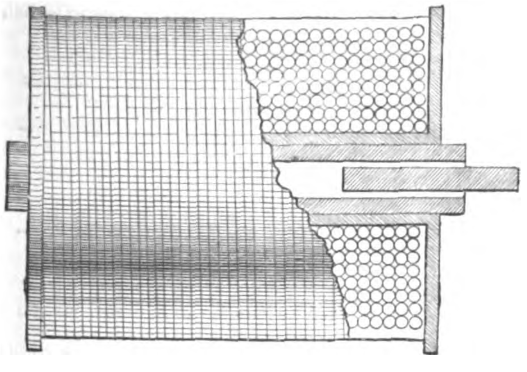

Fig. 53.—Electro-magnetic Pop-gun.

iron slab serves as a kind of yoke to carry the magnetism across the top. There are no fixed cores in the bobbins, which are entered by the ends of a pair of yoke plungers. Now in the ordinary Brush lamp for use with a steady current, the plungers are simply two round pieces of iron tapped into a common yoke; but for alternate-current working this construction must not be used, and instead a U-shaped double plunger is used, made up of laminated iron, rivetted together. Of course it is no novelty to use a laminated core; that device, first used by Joule, and then by Cowper, has been re-patented rather too often during the past fifty years to be considered as a recent invention.

The alternate rapid reversals of the magnetism in the magnetic field of an electro-magnet, when excited by alternating electric currents, sets up eddy-currents in every piece of undivided metal within range. All frames, bobbin tubes, bobbin ends, and the like must be most carefully slit, otherwise they will overheat. If a domestic flat-iron is placed on the top of the poles of a properly laminated electro-magnet, supplied with alternating currents, the flat-iron is speedily heated up by the eddy-currents that are generated internally within it. The eddy-currents set up by induction in neighbouring masses of metal, especially in good conducting metals, such as copper, give rise to many curious phenomena. For example, a copper disc or copper ring placed over the pole of a straight electro-magnet so excited is violently repelled. These remarkable phenomena have been recently investigated by Prof. Elihu Thomson, with whose beautiful and elaborate researches we have lately been made conversant in the pages of the technical journals. He rightly attributes many of the repulsion phenomena to the lag in phase of the alternating currents thus induced in the conducting metal. The electro-magnetic inertia, or self-inductive property of the electric circuit, causes the currents to rise and fall later in time than the electromotive forces by which they are occasioned. In all such cases the impedance which the circuit offers is made up of two things—resistance and inductance. Both these causes tend to diminish the amount of current that flows, and the inductance also tends to delay the flow.

### Electro-magnets for Quickest Action.

I have already mentioned Hughes's researches on the form of electro-magnet best adapted for rapid signalling. I have also incidentally mentioned the fact that where rapidly varying currents are employed, the strength of the electric current that a given battery can yield is determined not so much by the resistance of the electric circuit, as by its electric inertia. It is not a very easy task to explain precisely what happens to an electric circuit when the current is turned on suddenly. The current does not suddenly rise to its full value, being retarded by inertia. The ordinary law of Ohm in its simple form no longer applies; one needs to apply that other law which bears the name of the law of Helmholtz, the use of which is to give us an expression, not for the final value of the current, but for its value at any short time, $t$, after the current has been turned on. The strength of the current after a lapse of a short time, $t$, cannot be calculated by the simple process of taking the electromotive force and dividing it by the resistance, as you would calculate steady currents.

In symbols, Helmholtz's law is:—

$$i_t = \frac{E}{R}\left(1 - e^{-\frac{R}{L}t}\right).$$

In this formula $i_t$ means the strength of the current after the lapse of a short time $t$; E is the electromotive force; R the resistance of the whole circuit; L its coefficient of self-induction; and $e$ the number 2·7183, which is the base of the Napierian logarithms. Let us look at this formula; in its general form it resembles Ohm's law, but with a new factor, namely, the expression contained within the brackets. This factor is necessarily a fractional quantity, for it consists of unity less a certain negative exponential, which we will presently further consider. If the factor within brackets is a quantity less than unity, that signifies that $i_t$ will be less than E÷R. Now, the exponential of negative sign, and with negative fractional index, is rather a troublesome thing to deal with in a popular

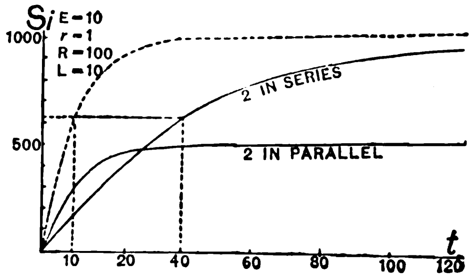

Fig. 54.—Curves of Rise of Currents.

lecture. Our best way is to calculate some values, and then plot it out as a curve. When once you have got into the form of a curve, you can begin to think about it, for the curve gives you a mental picture of the facts that the long formula expresses in the abstract. Accordingly we will take the following case. Let E=10 volts; R=1 ohm; and let us take a relatively large self-induction, so as to exaggerate the effect; say let L=10 quads. This gives us the following:—

| $t$ (sec.) | $e^{+\frac{R}{L}t}$ | $i_t$ |
|---|---|---|
| 0 | 1 | 0 |
| 1 | 1·105 | 0·950 |
| 2 | 1·221 | 1·810 |
| 5 | 1·649 | 3·936 |
| 10 | 2·718 | 6·343 |
| 20 | 7·389 | 8·646 |
| 30 | 20·08 | 9·501 |
| 60 | 403·4 | 9·975 |
| 120 | 162800·0 | 9·999 |

In this case the value of the steady current, as calculated by Ohm's law, is 10 amperes; but Helmholtz's law shows us that with the great self-induction, which we have assumed to be present, the current, even at the end of 30 seconds, has only risen up to within 95 per cent. of its final value; and only at the end of two minutes has practically attained full strength. These values are set out in the highest curve in Fig. 54, in which, however, the further supposition is made that the number of spirals S in the coils of the electro-magnet is 100, so that when the current attains its full value of 10 amperes, the full magnetising power will be S $i$=1000. It will be noticed that the curve rises from zero at first

Digitized by Google

steeply and nearly in a straight line, then bends over, and then becomes nearly straight again, as it gradually rises to its limiting value. The first part of the curve—that relating to the strength of the current after *very small* interval of time—is the period within which the strength of the current is governed by inertia (*i.e.*, the self-induction) rather than by resistance. In reality the current is not governed either by the self-induction or by the resistance alone, but by the ratio of the two. This ratio is sometimes called the "time-constant" of the circuit, for it represents *the time* which the current takes in that circuit to rise to a definite fraction of its final value. This definite fraction is the fraction $\frac{e-1}{e}$; or in decimals, 0·634. All curves of rise-of-current are alike in general shape—they differ only in scale; that is to say, they differ only in the height to which they will ultimately rise, and in the time they will take to attain this fraction of their final value.

*Example* (1).—Suppose E = 10; R = 400 ohms; L = 8. The final value of the current will be 0·025 ampere, or 25 milliamperes. Then the time-constant will be $8 \div 400 = \frac{1}{50}$th sec.

*Example* (2).—The P.O. standard "A" relay has R = 400 ohms; L = 3·25. It works with 0·5 milliampere current, and therefore will work with 5 Daniell cells through a line of 9,600 ohms. Under these circumstances, the time-constant of the instrument on short circuit is 0·0081 sec.

It will be noted that the time-constant of a circuit can be reduced either by diminishing the self-induction or by increasing the resistance. In Fig. 54 the position of the time-constant for the top curve is shown by the vertical dotted line at 10 seconds. The current will take 10 seconds to rise to 0·634 of its final value. This retardation of the rise of current is simply due to the presence of coils and electro-magnets in the circuit; the current as it grows being retarded because it has to create magnetic fields in these coils, and so sets up opposing electromotive forces that prevent it from growing all at once to its full strength. Many electricians, unacquainted with Helmholtz's law, have been in the habit of accounting for this by saying that there is a lag in the iron of the electromagnet cores. They tell you that an iron core cannot be magnetised suddenly; that it takes time to acquire its magnetism. They think it is one of the properties of iron. But we know that the only true time-lag in the magnetisation of iron—that which is properly termed "viscous hysteresis"—does not amount to any great percentage of the whole amount of magnetisation, takes comparatively a long time to show itself, and cannot therefore be the cause of the retardation which we are considering. There are also electricians who will tell you that when magnetisation is suddenly evoked in an iron bar, there are induction currents set up in the iron which oppose and delay its magnetisation. That they oppose the magnetisation is perfectly true; but if you carefully laminate the iron so as to eliminate eddy-currents, you will find, strangely enough, that the magnetism rises still more slowly to its final value. For by laminating the iron you have virtually increased the self-inductive action, and increased the time-constant of the circuit, so that the currents rise more slowly than before. The lag is not in the iron, but in the magnetising current, and the current being retarded, the magnetisation is, of course, retarded also.

### Connecting Coils for Quickest Action.

Now let us apply these most important, though rather intricate considerations to the practical problems of the quick working of the electro-magnet. Take the case of an electro-magnet forming some part of the receiving apparatus of a telegraph system, in which it is desired to secure very rapid working. Suppose the two coils that are wound upon the horse-shoe core are connected together in series. The coefficient of self-induction for these two is four times as great as that of either separately; coefficients of self-induction being proportional to the square of the number of turns of wire that surround a given core. Now if the two coils, instead of being put in series, are put in parallel, the coefficient of self-induction will be reduced to the same value as if there were only one coil, because half the line current (which is practically unaltered) will go through each coil. Hence the time constant of the circuit when the coils are in parallel will be a quarter of that which it is when the coils are in series; on the other hand, for a given line-current, the final magnetising power of the two coils in parallel is only half what it would be with the coil in series. The two lower curves in Fig. 54 illustrate this, from which it is at once plain that the magnetising power for very brief currents is greater when the two coils are put in parallel with one another than when they are joined in series.

Now this circumstance has been known for some time to telegraph engineers. It has been patented several times over. It has formed the theme of scientific papers, which have been read both in France and in England. The explanation generally given of the advantage of uniting the coils in parallel is, I think, fallacious; namely, that the "extra-currents" (*i.e.*, currents due to self-induction), set up in the two coils are induced in such directions as tend to help one another when the coils are in series, and to neutralise one another when they are in parallel. It is a fallacy, because in neither case do they neutralise one another. Whichever way the current flows to make the magnetism, it is opposed in the coils while the current is rising, and helped in the coils while the current is falling, by the so-called extra-currents. If the current is rising in both coils at the same moment, then, whether the coils are in series or in parallel, the effect of self-induction is to retard the rise of the current. The advantage of parallel grouping is simply that it reduces the time-constant.

### Battery Grouping for Quickest Action.

One may consider the question of grouping the battery cells from the same point of view. How does the need for rapid working, and the question of time-constant, affect the best mode of grouping the battery cells? The amateur's rule, which tells you to so arrange your battery that its internal resistance should be equal to the external resistance, gives you a result wholly wrong for rapid working. The supposed best arrangement will not give you (at the expense even of economy) the best result that might be got out of the given number of cells. Let us take an example and calculate it out, and place the results graphically before our eyes in the form of curves. Suppose the line and electro-magnet have together a resistance of 6 ohms, and that we have 24 small Daniell's cells, each of electromotive force, say, 1 volt, and of internal resistance, 4 ohms. Also let the coefficient of self-induction of the electro-magnet and circuit be 6 quadrants. When all the cells are in series the resistance of the battery will be 96 ohms, the total resistance of the circuit 102 ohms, and the full value of the current 0·235 ampere. When all the cells are in parallel the resistance of the battery will be 0·133 ohm, the total resistance 6·133 ohms, and the full value of the current 0·162 ampere. According to the amateur rule of grouping cells so that internal resistance equals external, we must

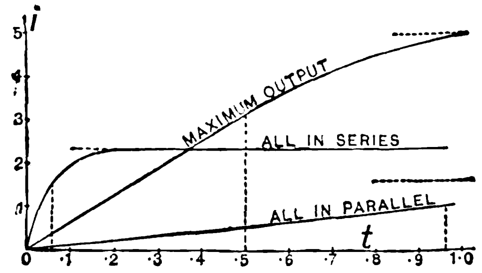

Fig. 55.—Curves of Rise of Current with Different Groupings of Battery

arrange the cells in four parallels, each having six cells in series, so that the internal resistance of the battery will be 6 ohms, total resistance of circuit 12 ohms, full value of current 0·5 ampere. Now the corresponding time-constants of the circuit in the three cases (calculated by dividing the coefficient of self-induction by the total resistance) will be respectively—in series, 0·06sec.; in parallel, 0·96sec.; grouped for maximum steady current, 0·5sec. From these data we may now draw the three curves, as in Fig. 55, wherein the abscissæ are the values of time in seconds, and the ordinates the current. The faint vertical dotted lines mark the time-constants in the three cases. It will be seen that when rapid working is required the magnetising current will rise, during short intervals of time, more rapidly if all the cells are put in series than it will do if the cells are grouped according to the amateur rule.

When they are all put in series, so that the battery has a much greater resistance than the rest of the circuit, the current rises much more rapidly, because of the smallness of the time-constant, although it never attains the same ultimate maximum as when grouped in the other way. That is to say, if there is self-induction as well as resistance in the circuit, the amateur rule does not tell you the best way of arranging the battery. There is another mode of regarding the matter which is helpful. Self-induction, while the current is growing, acts as if there were a sort of spurious addition to the resistance of the circuit; and while the current is dying away it acts of course in the other way, as if there were a subtraction from the resistance. Therefore you ought to arrange the battery so that the internal resistance is equal to the real resistance of the circuit, plus the spurious resistance during that time. But how much is the spurious resistance during that time? It is a resistance proportional to the time that has elapsed since the current was turned on. So then it comes to a question of the length of time for which you want to work it. What fraction of a second do you require your signal to be given in? What is the rate of the vibrator of your electric bell? Suppose you have settled that point, and that the short time during which the current is required to rise is

Digitized by Google

called $t$; then the apparent resistance at time $t$ after the current is turned on is given by the formula :—

$$R_t = R \times e^{\frac{R}{L}t} \div \left(e^{\frac{R}{L}} - 1\right).$$

TIME-CONSTANTS OF ELECTRO-MAGNETS.

I may here refer to some determinations made by M. Vaschy* respecting the coefficients of self-induction of the electro-magnets of a number of pieces of telegraphic apparatus. Of these I must only quote one result, which is very significant; it relates to the electro-magnet of a Morse receiver of the pattern habitually used on the French telegraph lines :—

| | L, in quadrants. |
|---|---|
| Bobbins, separately, without iron cores ......... | 0·233 and 0·265. |
| Bobbins, separately, with iron cores............... | 1·65 and 1·71. |
| Bobbins, with cores joined by yoke, coils in series........................................................ | 6·37. |
| Bobbins, with armature resting on poles......... | 10·68. |

It is interesting to note how the perfecting of the magnetic circuit increases the self-induction.

Thanks to the kindness of Mr. Preece, I have been furnished with some most valuable information about the coefficients of self-induction, and the resistance of the standard pattern of relays, and other instruments which are used in the British postal telegraph service, from which data one is able to say exactly what the time-constants of those instruments will be on a given circuit, and how long in their case the current will take to rise to any given fraction of its final value. Here let me refer to a very capital Paper by Mr. Preece in an old number of the *Journal* of the Society of Telegraph Engineers, a Paper "On Shunts," in which he treats this question, not as perfectly as it could now be treated with the fuller knowledge we have in 1890 about the coefficients of self-induction, but in a very useful and practical way. He showed most completely that the more perfect the magnetic circuit is—though, of course, you are getting more magnetism from your current—the more is that current retarded. Mr. Preece's mode of experiment was extremely simple; he observed the throw of the galvanometer when the circuit which contained the battery and the electro-magnet was opened by a key which at the same moment connected the electro-magnet wires to the galvanometer.

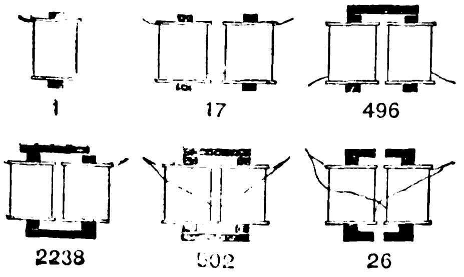

FIG. 56.—Electro-magnets of Relay, and their Effects.

The throw of the galvanometer was assumed to represent the extra current which flowed out. Fig. 56 represents a few of the results of Mr. Preece's Paper. Take from an ordinary relay a coil, with its iron core, half the electro-magnet, so to speak, without any yoke or armature. Connect it up as described, and observe the throw given to the galvanometer. The amount of throw obtained from the single coil was taken as unity, and all others were compared with it. If you join up two such coils as they are usually joined, in series, but without any iron yoke across the cores, the throw was 17. Putting the iron yoke across the cores, to constitute a horse-shoe form, 496 was the throw; that is to say, the tendency of this electro-magnet to retard the current was 496 times as great as that of the simple coil. But when an armature was put over the top the effect ran up to 2,238. By the mere device of putting the coils in parallel, instead of in series, the 2,238 came down to 502, a little less than the quarter value which would have been expected. Lastly, when the armature and yoke were both of them split in the middle, as is done in fact in all the standard patterns of the British Postal Telegraph relays, the throw of the galvanometer was brought down from 502 to 26. Relays so constructed will work excessively rapidly. Mr. Preece states that with the old pattern of relay having so much self-induction as to give a galvanometer throw of 1688, the speed of signalling was only from 50 to 60 words per minute; whereas, with the standard relays constructed on the new plan, the speed of signalling is from 400 to 450 words per minute. It is a very interesting and beautiful result to arrive at from the experimental study of these magnetic circuits.

* *Bulletin de la Société Internationale des Electriciens*, 1886.

SHORT CORES *versus* LONG CORES.

In considering the forms that are best for rapid action, it ought to be mentioned that the effects of hysteresis in retarding changes in the magnetisation of iron cores are much more noticeable in the case of nearly-closed magnetic circuits than in short pieces. Electro-magnets with iron armatures in contact across their poles will retain, after the current has been cut off, a very large part of their magnetism, even if the cores be of the softest of iron; but so soon as the armature is wrenched off the magnetism disappears. An air-gap in a magnetic circuit always tends to hasten demagnetising. A magnetic circuit composed of a long air-path and a short iron-path demagnetises itself much more rapidly than one composed of a short air-path and a long iron-path. In long pieces of iron the mutual action of the various parts tends to keep in them any magnetisation that they may possess; hence they are less readily demagnetised. In short pieces, where these mutual actions are feeble or almost absent, the magnetisation is less stable, and disappears almost instantly on the cessation of the magnetising forces. Short bits and small spheres of iron have no "magnetic memory." Hence the cause of the commonly received opinion amongst telegraph engineers that for rapid work electro-magnets must have short cores. As we have seen, the only reason for employing long cores is to afford the requisite length for winding the wire which is necessary for carrying the needful circulation of current to force the magnetism across the air-gaps. If, for the sake of rapidity of action, length has to be sacrificed, then the coils must be heaped up more thickly on the short cores. The electro-magnets in American patterns of telegraphic apparatus usually have shorter cores, and a relatively greater thickness of winding upon them, than those of European patterns.

(*To be continued.*)

## ELECTROLYSIS OF ALUMINIUM FLUORIDE.*

BY M. ADOLPHE MINET.

The author, by continuing his researches on the electrolysis of the fused fluoride of aluminium, has been able to determine the composition of the electrolytic bath, which, for a given temperature and current density, yields the best results. The physical properties of the mixture of salts, and the relation between the current density and the constants of electrolysis, have also been found.

*Composition of the Bath.*—The bath is formed of a mixture of sodium chloride, and the double fluoride of aluminium and sodium. It is expressed by the chemical formula $6\,NaCl + Al_2Fl_3, 3\,NaFl$. Its fusing point is 675°C., and the temperature of vaporisation 1035°C. Its electrical conductivity at the temperature t°C. is expressed by the formula

$$C_t = 3{\cdot}1\,[1 + 0{\cdot}0022\,(t - 870^{\circ})].$$

For a current of 1,200 amperes the weight of the bath should be 20 kilogrammes, the current density should be 1 ampere per square centimetre of active surface of the positive electrode, and the voltage of the electrodes should be 5·5 volts.

The composition of the bath is maintained constant by adding a mixture of aluminium hydrate, oxyfluoride of aluminium, and the double fluoride of aluminium and sodium, by the action of which the aluminium disengaged at the positive electrode is reabsorbed by the mixed electrolyte.

*Relation between the Current Density and the Electrolytic Constants.*

Let V be the voltage applied to the electrodes, $e$ the opposing electro-motive force in volts due to the polarisation of the electrolyte, R the resistance in ohms of the electrolyte, and C the current in amperes.

When the salts composing the bath are chemically pure, we may then distinguish three cases. In the first the current density is very small, and V and $e$ are practically identical. If the temperature is constant, V is found proportional to C until the current density reaches an upper limit. This limit, when the temperature $t$ is 870 deg., varies between 0·02 and 0·03 amperes per square centimetre. Beyond this limit, and until the current density exceeds 1 ampere per square centimetre, the formula $V = e + R\,C$ holds, and the author gives several numerical results obtained from experiment and calculation. A few are appended below :—

| $t$=852°C, $e$=2·15, R=0·01 | | | $t$=890°C, $e$=2·40, R=0·0044 | | | $t$=980°C, $e$=0·34, R=0·0033 | | |
|---|---|---|---|---|---|---|---|---|
| C | V Measured. | V Calculated. | C | V Measured. | V Calculated. | C | V Measured. | V Calculated. |
| 130 | 3·50 | 3·45 | 196 | 3·26 | 3·26 | 572 | 4·23 | 4·23 |
| 245 | 4·60 | 4·60 | 885 | 6·18 | 6·29 | 1030 | 5·78 | 5·74 |

* *Comptes Rendus*, October 27, 1890.

Digitized by Google

When the current density exceeds one ampere per square centimetre the value of V cannot be calculated as a function of C in any simple way. It rapidly attains a magnitude approximating to that required for an electric arc 30 or 40 volts.

When the electrolyte is mixed with extraneous salts, such as those of iron or silicon, it is still true that while the current density lies between certain limits the decomposition takes place according to Sprague's law. The following numbers were obtained from experiments on a bath, from which the salts of iron and silicon were successively removed.

| Iron present. $t=810°C.$ $e=0·75.$ R=0·0093. | | | Silicon present. $t=840°C.$ $e=1·37.$ R=0·0089. | | | Aluminium salts only. $t=870°C.$ $e=2·15$ R=0·0085. | | |
|---|---|---|---|---|---|---|---|---|
| C | V | | C | V | | C | V | |
| | Measured. | Calculated. | | Measured. | Calculated. | | Measured. | Calculated. |
| 75 | 1·45 | 1·45 | 65 | 1·95 | 1·95 | 100 | 3·00 | 3·75 |

## THE MOST FAVOURABLE POSITION FOR AN ELECTRIC LIGHT CENTRAL STATION.*

BY DR. A. FÖPPL.

As the question very frequently arises as to which is the best situation for a central station so far as the cost of mains is concerned, the following simple considerations, which do not require any complicated calculations, may be of use :—

If there are any number of points 1, 2, 3 . . . which may be regarded as centres for distribution, the mains to these points from the central station, O, must obviously, if practicable, lie in straight lines. Suppose $l_1$ $l_2$ $l_3$ . . . to be the lengths of these mains and $c_1$ $c_2$ $c_3$ . . . the respective currents, they will be called on to carry. The weight of copper required for the main $l_1$ will then be $k\ c_1\ l_1^2$, where $k$ is a coefficient depending on the tension, and, therefore, in our case a constant. The total weight of copper required for the mains is accordingly $k\ \Sigma\ c\ l^2$, the sum being taken over all the distributing centres of the system. But this expression is of the same form as that for the moment of inertia about 0 of masses proportional to $c_1$ $c_2$ $c_3$ placed at the distributing centres. But the moment of inertia is a minimum when the point about which it is taken is the centre of gravity of the system. We accordingly have the law :—The weight of copper required for the mains will be a minimum when the central station is placed at the centre of gravity of the system formed by placing masses proportional to the current consumed at each one of the distributing centres. Further, we know that the moment of inertia about any point distant $r$ from the centre of gravity of any system is equal to the moment of inertia about the centre of gravity $+ r^2\ \Sigma\ m$. From this we deduce the law that the weight of copper in the mains is the same when the central station is at any point on the circumference of a circle described with the centre of gravity, as determined above, for centre.

In order to apply the laws found to an example, the centre of gravity as defined is first found. Various values are then put for the moment of inertia about a point, and the distance of the point accordingly from the centre of gravity determined. These distances are taken as radii, and concentric circles are drawn with the centre of gravity for centre. It is then possible to see at a single glance the increase per cent. in weight of copper in the mains necessitated by removing the central station to any distance from the centre of gravity.

## GERMAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

*November* 17, 1890.

The Darmstadt central station which was opened two years ago, with a capacity of 6,000 lamps, and which was built on the three-wire system, offers a splendid illustration of some of the advantages and disadvantages of the low-tension continuous-current system. The station supplies at present current for 7,000 lamps, when the accumulators are helping the machines. But there is still an increasing demand for light, and to avoid a still greater overloading, the engineers of the work are compelled to use a strange expedient. When anybody wants to have the light in a street where there are no cables, they ask them to pay five per cent. of the cost of the main cable to be laid. How they avoid new consumers in streets where there *are* mains I have not been able to find out. The central station is situated nearly in the centre of the town, and from there the feeders and mains spread through a circular area of 600 metres diameter. As all the ground around the building is occupied, it is rumoured that the municipalty is going to erect the second central station somewhere at the further end of the town, and that as there is also a demand for a new technical college, they propose to place the physical and electrical colleges in the central station buildings. This would certainly be to the benefit of the students; whether it would also prove a benefit to the station is a question.

There is a project on foot to build an electric tramway between Nürnberg and Fürth. These two Bavarian towns were the first in Germany to be united by a railway in December, 1835, and it may be of interest to state that the first locomotive built by Stephenson was in active service on it till 1887. If the electric line be made, Messrs. Schuckert, of Nürnberg, will probably have the contract.

The small town of Pforzheim is about to invite tenders for a 200 horse-power central station for the distribution of current to small electric motors. If the idea is proceeded with, this town will be the first in Germany to have a central station erected mainly to supply motive power.

## CORRESPONDENCE.

### THE TRANSMISSION OF ENERGY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR : With reference to your Editorial note, drawing attention to the contrast between the mechanical and the electrical manner of transmitting energy, *i.e.*, between the transmission of power by ordinary matter and by the ether, it is, perhaps, worth mentioning explicitly and briefly that the transmission of power by cog-wheels is extremely analogous to the electrical method. Consider a simple pair of cog-wheels in the same plane, say, one above driving or driven by another below. The axis of rotation lies, say, north and south, the direction of motion of the engaging cogs is east or west, the path of the transmitted energy is up or down. Energy moves perpendicularly to both the electric current and the magnetic axis. The motion of the rim of a cog-wheel is tangential; the transmission of energy by it is radial. The analogy bears some pressing. I doubt, however, whether many engineers have yet grasped the fact that energy is a definite thing, transmitted continuously from place to place like matter with no sort of discontinuity; so that its path, *viâ* belts, or shafting, or mill gearing, or dielectrics, is a thing which can be definitely studied and mapped out.—Yours, &c.,

OLIVER J. LODGE.

### LOSSES IN TRANSFORMERS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR : In your issue of October 10th you have commented on some views which I have expressed elsewhere in regard to Mr. Swinburne's transformer. You have misunderstood some of my arguments, but the fault is entirely my own. As I value highly your opinion and that of your eminent co-workers, and am anxious that my views—correct or erroneous—should be so understood by your readers as I intended, I take the liberty to address you the following explanatory lines which you may deal with as you deem proper.

Digitized by Google

I imagine—for reasons which will subsequently be made clear—that a line through, say, the axis of a core, which constitutes in part the magnetic circuit of a transformer or other induction apparatus, be subdivided in units of length and the line integral taken along the line, then the total line integral is equal to the sum of all these unit integrals or "magnetomotive forces per unit length," if I am allowed to use this expression. These unit integrals are of necessity not equal since the magnetic force diminishes as we recede from the region adjacent to the coil or magnet energising the core. Usually, the magnetic force is taken as constant throughout the core, and in estimating the dissipation no account is taken of the fact that the same may be very different in the different parts of the core. As this statement might require an explanation I will illustrate it with an example. Suppose you take a transformer core consisting of a middle piece and the two sides embracing the coils, and you wind a coil on the middle piece leaving both the sides free as usual. If you pass an alternating current through the coil a certain amount of energy will be dissipated in the core, the dissipation will be equal in both the sides, and, of course, since the proper design requires that the section of each side piece should be equal to half the section of the middle core, the dissipation in both the sides together will be very nearly equally to that in the middle core. Mr. Swinburne has stated that in removing the sides the loss would be divided by three, and I was somewhat misled by his statement. Suppose now you wind on one of the side cores a coil and close the same upon itself. A very different distribution of the lines will now result. As the phase difference of the currents in both the coils will be more or less approximating to 180deg., the current in the closed coil must by taken negative, for the core upon which the coil is wound and positive for the other side core, hence the "magnetomotive forces" in both the circuits are very different. The closed secondary coil does not allow many lines to pass through the core it embraces. As a result, the loss in the other side core will be much greater. An analogous experiment may be performed with an electric circuit by setting up in one of two branches through which the current divides an opposing electromotive force of some kind. Like in an electric circuit, so in this example, one branch is inert and the other possesses self-induction so to speak. Of course the above example is exaggerated, and it is only given for better illustration. In practice, one of the side cores is replaced by air, and the case corresponds more to a core having a primary coil on one end and a secondary at the remote end. In this case, also, by closing the secondary coil a different line density in the various parts of the core will result, and the loss in the various parts will be different. Some phenomena observed on transformers, under overload, for instance, may be explained by taking into account the above effects.

Now, to come to the subject of this letter. I beg you will please to observe that Mr. Swinburne in his communication stated first, that in removing the embracing sides—that is, reducing the length to one-third to all appearance—the loss is divided by three (he evidently took the section of each of the sides to be equal to the section of the middle piece, probably without noticing that this assumption was important for his argument); and later he remarked that in his transformer the loss was below 1 per cent., that is, one-tenth of the loss in the closed circuit transformer. Following his reasoning I was under the impression that he had reduced the length of the core to one-tenth. My statement then, "in order that the loss might be reduced to one-tenth, it is necessary to reduce the weight of the core to one-tenth, and subject every unit length of the same to the same magnetomotive force," meant broadly to say, that if we take a core of a length L and operate it with a certain number of ampere turns, and then take a length $\frac{L}{10}$ of that core, and operate with the same ampere turns, the loss will generally not be one-tenth, though the weight *is* one-tenth, but may be greater or smaller. The same, in comparing two cores exactly alike and operated with the same ampere turns, we shall find that the loss will not be the same in both cases unless there is "per each unit of length the same magnetomotive force," or, in other words, unless the exciting coils are distributed alike. We can also easily see that a transformer core of a given length and section is most economically utilised when both the primary and secondary coils are distributed uniformly over whole core. But even in such a case, I have sufficient reason to believe that the various parts of a core (of a transformer of any kind or armature of a dynamo machine) are not utilised alike; that the line density is different in the different parts, that it is greater near the surface, or, rather, near the conductors conveying current, and that this condition is greatly affected by the periodicity, or, in dynamo machines, by the peripheral speed and number of poles. This condition may more or less modify the losses found on cores.

In his communication, Mr. Swinburne further stated that in his transformer the magnetomotive force and the exciting current were higher, but it did not appear as though he *sufficiently* appreciated the increased loss in consequence of the increased excitation. I meant to point this out by stating that "if a higher magnetomotive force is used, the loss will be proportionate to the square of the magnetomotive force."

At any instant the "magnetomotive force" corresponds to the instantaneous integral current value around the core, which value is computable from the primary and secondary turns and both the current ordinates at *that instant*. Since the magnetomotive force is 4 $\pi$ times that value, when, considering mere proportionality, that value alone need be considered, and my above quoted remark means that the loss is proportionate to the square of that value. In a closed circuit transformer in which the primary and secondary circuits are in very close inductive relation, and the increase of the inducing and induced currents is in a practically constant ratio, this value, and therefore the "magnetomotive force," remains constant for all loads, hence the loss is practically the same for all loads. It is more or less the value which we obtain from the primary current and turns when the secondary is open. If, under otherwise equal conditions of test, the electromotive force on the primary of a converter, or on a choking coil, is varied, the current is varied in proportion, and the above value is proportionate to the electromotive force. About two years ago, Dr. Louis Duncan pointed out that the loss in a core is nearly proportionate to the square of the electromotive force. In laboratory experience on motors and induction-cores, this proportionality has been found to exist, being more pronounced at high frequencies than at low, probably on account of the relatively greater loss in currents in the former case.

You have evidently misunderstood some of these statements. I did not say that in general the loss is independent of the length of the core as you seem to infer. I only stated that "magnetic resistance" has *little* to do with efficiency, and I gave the example of the two rings of different diameter as such a particular case in which "magnetic resistance" (and therefore length) is of comparatively small importance, and also to draw attention to the advantages of the "top-winding," which by many is not sufficiently appreciated, and which is the greater the longer the core and the higher the frequency.

Your reflections about the "relative magnitude of the waste due to eddy currents" and hysteresis induce me to say a few words about this subject to which I have devoted considerable thought.

I do not think that eddy currents, that is, currents circulating in paths of measurable length, are in a properly subdivided core as important an element of loss as it is generally assumed. In subdividing a core we soon reach a point where a further subdivision would be of no appreciable advantage, judging from the rapid diminution of the eddy-current effect as the thickness of the plates or wires is reduced, and, in fact, in practice it is better not to carry the subdivision too far for various obvious reasons, which, however, are not concerned in this argument. Now hysteresis loss, according to the accepted views, is a result of the periodic displacement of the molecular magnets. As far as this loss in a core is concerned, we can reduce it to anything desired. Imagine that in Ewing's experiments we apply to the pivoted magnets a magnetising force varying periodically many thousand times a second. Of course the magnets would not stir, but loss would nevertheless occur in a core composed of such magnets in consequence of currents set up in them. Since the magnets would not move (that is, not to any appreciable extent), there would then be no magne-

Digitized by Google

tisation, therefore no loss in hysteresis proper, but all the loss would practically be due to currents. We may now replace the magnets by small closed coils possessed of a directive tendency. When a current impulse is started in the coil which surrounds the small coils, currents will be set up in the latter. The tendency of the currents generated would be to place each small coil in such a position that no current is generated in it, that is, at right angles to the large energising coil, and certain positions of the small coils would result from this and the directive tendency and the interaction of the coils. When the currents subside the directive force would act, and bring the coils more or less in their former positions. When a current of opposite direction is generated in the small coil, a similar displacement would result, but in this case the displacement would be smaller or greater, according to the direction of the induced current, which may aid or oppose the directive force which the coils possess in virtue of their being magnets. If the coils would be devoid of inertia, and could move with perfect freedom, no current would be generated in them; but they possess weight and inertia (and directive tendency besides); time is therefore required to move them. As we increase the frequency the energy and duration of each current impulse is diminished, and soon a point is reached where the energy and time are not sufficient to move the coils into the positions which constitute magnetisation. Currents are then generated to their full value. At low frequencies the loss would be principally due to hysteresis proper; at excessively high frequencies the loss in hysteresis would be small, if any, and the loss in currents great.

We may conceive the core to consist of rings or similarly-shaped aggregations of atoms, which may be compared with so many closed coils, so that the described effects occur.

There are a good many reasons why I think that eddy currents in a well laminated core do not play an important part. They diminish rapidly as the lamination is carried further. Then, again, if we insert in a coil a bundle of thin wires, and pass an alternating current through the coil, the heating of the wires will be principally due to currents circulating, not through the mass from wire to wire, but in each individual wire, as the resistance to currents from wire to wire would be comparatively very great. Now each wire we may consider as consisting of a bundle of far thinner wires, each formed by a row of molecules with spaces between, and it seems probable that similar conditions must prevail.

On grounds of the view above given I have thought that the relative magnitude of the hysteresis and current loss may be determined by operating at an excessively high frequency, when there is little or no loss in hysteresis, and then from the value found, and from the time-rate of change at this and at a lower frequency, estimating the amount of the current loss with the lower frequency.—Yours, &c., NIKOLA TESLA.

## A NEW EMPIRICAL FORMULA FOR THE AIR-SPACE OF DYNAMOS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Mr. Andersen's formula is so very startling that I think he will find that an error has crept into his calculations.

Without going into the subject any further, I would refer him to *Electrician*, Vol. XVIII., p. 39, in which is commenced a full report of a Paper on "Dynamo Electric Machinery," by Drs. J. and E. Hopkinson. This I take to be the standard publication on the subject. I see that Mr. Andersen does not take into account the question of leakage. Perhaps this is where the error can be found.—Yours truly,

H. RAVENSHAW.

## PROF. KIMBALL AND ELECTRICITY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The article which appeared on page 33 of your previous number, from the pen of Prof. Kimball, of Baltimore, has given me both surprise and pleasure. That you may know the cause of this, I quote the following from it:—

"It is an interesting fact that the old notion that electricity is a substance, one of the so-called class of imponderables held by the earlier investigators of electrical phenomena, after being generally supposed to be dead and buried, should be resurrected, and, in a dress to suit the times, should become a part of the orthodox scientific creed of to-day. . . . The modern theory differs from the older ones, however, in this important respect, that, whereas Franklin thought of each particle of the electric fluid as acting at a distance, repelling every other particle, the modern theory supposes no such repulsive force."

These passages of Dr. Kimball's embody the theory of electricity which I was enabled to publish in 1839, from the experiments and discoveries I then made about electricity. Why Dr. Kimball should have written that this theory is "a part of the orthodox scientific creed of the day" has somewhat puzzled me; it is possible his words may be true on the other side of the Atlantic, but they are, I am sorry to write, wide of the truth on this side of the Atlantic, for all the treatises on electricity which have hitherto been published in this country by our professors and teachers of electricity, within and outside of our colleges, have all been written so as to teach that Faraday's theory of two electric forces is true; whereas the theory Dr. Kimball now assists me in upholding, and the discoveries I made which enabled me to promulgate it in 1839 are a demonstration that Faraday's theory of two electric forces is utterly false. The two theories cannot co-exist, and yet Dr. Kimball has tried to make them do so, for he has written: "It appears, then, that the characteristic distinction between the older and modern theories of electricity is the recognition by the latter of the fundamental importance of the *dielectric* or insulating media. This great step forward was made by Faraday." I maintain that Faraday's theory of the *dielectric* must live or die with his theory of two electric forces. It is strange that Dr. Kimball did not see this. Faraday's theory of the *dielectric* is, that electricity passes through glass by means of that which he called *induction*, namely, that each atom of the glass is polarised by his imaginary two electric forces. Now, if Dr. Kimball really believes in the theory of only one electricity—a peculiar substance, as he describes it—then he should also believe that Faraday's two electric forces are defunct, and consequently that his theory of the *dielectric* is also defunct. One of the reasons why I was enabled to publish in 1839 my theory of one electricity having no repulsion for the particles of electricity, in opposition to Franklin's one theory of electricity, was the fact that I discovered that electricity passed through glass by *conduction*, and not by Faraday's imaginary thing called *induction*. The experiments which prove this I have shown to many electricians, and will be glad to show them at my laboratory to any electrician who arranges with me by letter as to a day and hour for seeing them.—Yours truly, JAMES JOHNSTONE.

8, Merchiston-park, Edinburgh, November 18, 1890.

## THE COLOGNE ELECTRIC LIGHT CABLES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In your issue of October 31st, your German Correspondent states that the cables which are being laid down in the streets of Cologne have been manufactured by "MM. Chaudoir, of Neuchâtel." We take the liberty to call your attention to the fact that there is no such firm in Neuchâtel, and that all the cables for the central station of Cologne are manufactured in our works.—Yours truly,

SOCIÉTÉ D'EXPLORATION DES CABLES ÉLECTRIQUES,
SYSTÈME BERTHOUD, BOREL ET CIE.

Cortaillod, November 7, 1890.

[Our German Correspondent informs us that "Chaudoir, of Neufchâtel," was an unfortunate slip of the pen for "Cortaillod, near Neufchâtel," where the cables in question are manufactured. ED. *E.*]

## THE ELECTROLYTIC PREPARATION OF BLEACHING AGENTS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The paragraph which deals with my process in your article of last week on "The Electrolytic Preparation of Bleaching Agents," translated from *La Lumière Electrique*, is merely

Digitized by Google

an extract of a patent which I did not consider worth protecting in England, owing to the improvements I have since introduced in my bleaching process, and in which I dispense altogether with carbon electrodes.

The example I quoted in my specification to give an idea of the production and cost of hypochlorite of sodium in comparison with bleaching powder is hypothetical, and, in practice, the cost of the electrolytic production of equivalent quantities of bleaching powder is much lower than I stated in my specification.

Through a misprint, the advantages of my process, compared with chemical bleaching, are lessened because the article I refer to says: "In order to obtain a quantity of bleaching liquor *equal to one ton of chloride of lime*, 4,000 *horse-power hours* are required. If 1½ kilog. of coal is consumed per horse-power hour, the coal consumption for 4,000 horse-power hours will be 6 tons, and taking coal at 20fr., the cost of production is still less than one-half the price of a ton of chloride of lime."

What I said in my specification is, that, assuming the yield of chlorine is only 1 gramme per ampere hour, 4,000 horse-power hours will produce a quantity of chlorine equivalent to *one ton and a-half* of the bleaching powder, and not one ton only. A difference of half a ton is not a negligible fraction of one ton and a-half. Given that a 1,000 amperes and 5 volts dynamo yield 1 kilo. of chlorine per hour, a 1,000 amperes and a 100-volt dynamo will yield, after 1 hour, 20 kilos., and after 24 hours 480 kilos. of chlorine, equal to 1,440 kilos. of bleaching powder, almost one ton and a half. To obtain 1 kilo. of chlorine, 5,000 watt hours are required. If we take the brake horse-power to be equal to 600 watts, it requires 8·33 horse-power, and the price of 1 kilo. of chlorine is therefore the cost of 8·33 horse power per hour. In a set of 20 tanks 166·66 horse-power are necessary to generate 20 kilos. of chlorine per hour, and for the constant generation of these 20 kilos. of chlorine per hour, during 24 hours, 3,998 horse-power hours are necessary, and will have transformed a given quantity of chloride of sodium solution into a hypochlorite of sodium solution, containing 480 kilos. of chlorine. Assuming that the consumption of coal is 2½lb. per horse-power per hour, it will represent, in round figures, six tons. Adding to the cost of this that of the salt lost and other items, the production of hypochlorite of sodium containing the same quantity of chlorine as a given quantity of bleaching powder will cost about 50 per cent. less than the powder. If the consumption of coal is only 2lb. per horse-power hour, and if the yield of chlorine per ampere hour is over 1 gramme, my electrolytic bleaching will be cheaper still.

With regard to the article on bleaching by ozone, written by Mr. A. Villon, in his own paper, *La Revue de Chimie Industrielle et Agricole*, of which you gave an extract, I may say that as soon as I read it in the several Paris papers in which it was reproduced, I made inquiries about the new system, asking where it was worked, and whether it was only a laboratory experiment, or if it was applied on a commercial scale? Nobody knew anything about it. I wrote to Mr. Villon himself, and then to MM. Broyer et Petit, who were described in the article as working an apparatus capable of producing 10 cubic metres of ozone per hour. I enclose their letter, dated September 1, 1890, by which you will see that they say they do not know the Villon process.—Yours truly,

62, Loughborough-park, S.W. E. ANDREOLI.

**Hotel Lighting in America.**—Perhaps no class of buildings in New York City is so admirably fitted with electric lighting plants as the hotels and theatres, says the *Electrical World*. At the Plaza Hotel, however, where four 650 light machines are installed, the thing seems to have been done rather too well. The floor of the dynamo room, says our contemporary, is of polished marble, white and grey in colour, and, although very handsome in appearance, it does not give the best satisfaction, owing to the fact that the insufficient ventilation of the room causes the temperature to reach a rather high point, and this keeps the marble floor hot at all times, producing somewhat unpleasant results.

## TRADE NOTES AND NOTICES.

TENDERS WANTED.—Tenders are required for lighting public hall, stores, &c., at Edmonton. Particulars may be obtained from Mr. Walker, People's Provider, Upper Edmonton.

SURVEYING INSTRUMENTS FOR SALE.—Our advertisement columns contain a notice of a sale of forty 5in. by 4in. theodolites and 9in. contouring levels, being a portion of surplus stock. Full particulars may be obtained from the officer in charge of stores, Ordnance Survey Office, Southampton.

ELECTRIC METER PATENTS.—In our advertisement columns will be found particulars of a notification by Messrs. Oulton and Edmondson for "leave to amend specification and letters patent No. 11,032 of 1889 for improvements in electric meters."

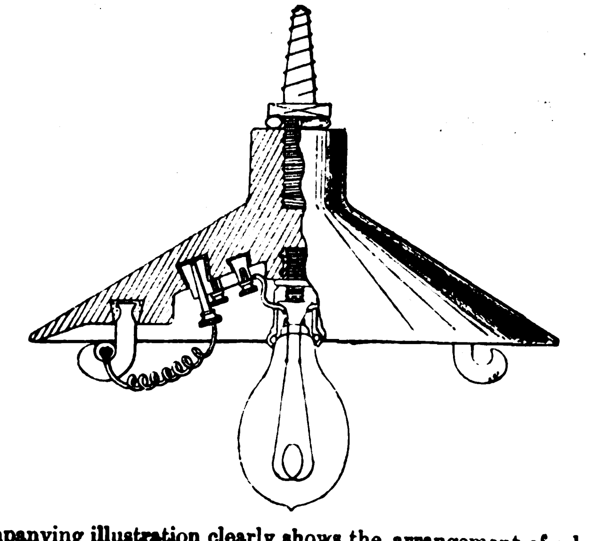
PORCELAIN FITTINGS.—In reference to our Trade Note upon the subject of threading with a fine thread the small holes in porcelain switches, &c., Messrs. Poole and White inform us that they have sold thousands of switches during the past six months which have been similarly treated. The porcelain fittings were made for Messrs. Poole and White by a well-known firm in the Midlands.

AMALGAMATION OF BUSINESSES.—We are informed that the business hitherto carried on by Sydney F. Walker and Co., at 92, Quayside, and by R. H. Barnett and Co., at Elswick-court, Newcastle-on-Tyne, will in future be carried on by Messrs. R. H. Barnett and A. S. Barnard, at 92, Quayside, Newcastle-on-Tyne, as "Barnett, Barnard and Co.," Electrical and General Engineers and contractors.

REMOVAL.—Messrs. William Coward and Co., agents for the Australian Gas Light Company, Sydney, have removed to 11, Queen Victoria-street, London, E.C.

——— The Elmore Companies are removing from 20, Bucklersbury, E.C., to 64, Cannon-street, London, E.C.

PORCELAIN INSULATOR FITTINGS FOR MINES.—In our last issue a description was given of these very ingenious fittings which are being supplied by the Electrical Engineering Corporation. The



accompanying illustration clearly shows the arrangement of a lamp beneath a massive porcelain shade, the whole of the contacts, cut-out, switch, &c., being under cover, and thus not only protected from dripping water but kept warm and dry by the lamp.

MESSRS. CECIL WRAY AND COMPANY.—This firm informs us that they are now carrying on the lighting station at Bradford set up by the Schmidt-Douglas Company, Limited.

FRENCH TELEGRAPHS.—The French Government have in contemplation the re-adjustment of the Paris telegraph and pneumatic tube service. It is proposed to make this service much more complete than it is at present.

## PATENT RECORD.

### APPLICATIONS FOR PATENTS.

October 30, 1890.

17,335. F. B. FAWCETT. Weston-super-Mare. Improvements in electric motors.

17,375. J. B. DENIS. London. An electric motor.

17,394. L. V. CHABRAND. London. Apparatus for effecting a permanent make or break of an electric circuit at any suitable number of points.

October 31, 1890.

17,444. M. MÜTHEL. London. An improved filling for galvanic batteries.

Digitized by Google

17,459. F. V. Maquaire, London. Improvements in and relating to electric arc lamps.

17,488. J. A. Radley. Norwich. Pivoted lamp-post for electric lighting.

November 1, 1890.

17,532. J. Collins. London. Improvements in electric motors.

17,558. J. W. Rathbone. London. Portable generator and electrometer for testing insulation resistance of electric wires.

17,560. J. A. Iliffe, and H. Barton. London. Improvements in and relating to locked switches for electric current circuits.

November 3, 1890.

17,580. J. M. M. Munro. Glasgow. Improvements in the decorative arrangement of electric lights.

17,589. C. Barnett. Godalming. Improved means for lighting street gas lamps by electric spark.

17,600. A. C. Lainchbury. Edmonton. An electrical switch for opening and closing of circuits, switching on currents, and so forth.

17,611. C. D. Abel. London. Improved electrical push button for signalling circuits (H. Messing, Germany).

17,631. P. Lauber. London. Improvements in or relating to electric accumulators.

17,635. P. Schoop. London. Improvements in electrodes and isolators or divisions for batteries.

November 4, 1890.

17,690. C. A. Randall. London. Method of and apparatus for obtaining electricity by hydraulic power.

17,711. H. Edmunds. London. Improvements in means for the distribution of electricity.

17,728. M. W. Dewey. London. Improvements in electric railways.

17,735. F. J. Cleaver and G. Fassold. London. Improvements in automatic regulators for dynamos and motors.

November 6, 1890.

17,829. J. E. Charnock. Manchester. Improvement in incandescent lamp holders or suspenders (C. Charnock, Russia).

17,851. H. Binko. London. Improvements in electric thermostats for ships' bunkers, refrigerating rooms, and other purposes.

17,852. H. Binko. London. Improvements in magneto generators for signalling or medical purposes.

17,861. J. Marx. London. Improvements in the manufacture of electrical conductors and electrodes, and for connecting them, and for analogous purposes.

17,863. M. P. Hardt. London. Improvements in portable electric lamps.

17,870. W. McGeoch. London. An improved make and break action adapted to the purpose of an electric switch.

November 7, 1890.

17,899. W. Lownds, E. Emanuel, and J. Wood (of the firm of A. Emanuel and Sons, Limited). London. An improved self-locking electric switch.

17,905. C. T. B. Brain. Helsby. An induction transformer coil, and methods of using the same for telephone call bells and other purposes.

17,912. J. T. Bottomley. Glasgow. An electricity meter.

17,929. B. Rejchman. London. Improvements in or connected with armatures for dynamo-electric machines.

17,937. F. V. Maquaire. London. Improvements in and relating to electric lamps or lighting apparatus.

17,941. Siemens Brothers and Co. (Limited). London. Improved means for charging accumulator batteries on electric circuits supplied by current generators (Siemens and Halske, Germany).

17,951. H. H. Lake. London. Improvements in electric switches (F. C. Jenkins, Germany).

17,954. H. L. Mangras. London. Improvements in electrical accumulators or storage batteries.

# COMPANIES' MEETINGS & REPORTS.

## Eastern Extension, Australasia, and China Telegraph Company (Limited).

An extraordinary general meeting of this Company was held at the offices, Winchester House, Old Broad-street, on the 19th inst., for the purpose of confirming, as a special resolution, the following resolution, which was passed at the meeting of the Company on the 22nd ult. Sir John Pender, K.C.M.G., occupied the chair.

"*A. That the Board of Directors be, and are hereby authorised from time to time to create and issue Mortgage Debenture Stock of the Company to an amount not exceeding one-third of the share capital of the Company for the time being issued and paid-up, upon the terms that the aggregate amount of the said stock for the time being in issue, and the interest thereon, shall rank* pari passu *as a first charge on the undertaking and revenue of the Company, the Stock to be issued at such times, in such amounts, and on such terms and conditions as the Board shall from time to time determine, for the purpose of redeeming by exchange or otherwise the outstanding Debentures of the Company, or any other purpose to which capital of the Company may be lawfully applicable.*"

"*B. That the Board be and are hereby authorised to make such provision as they think fit for the registration and transfer of Mortgage Debenture Stock, and for the delivery of certificates thereof, and for the payment of the interest thereon, and generally as to the form and incidents of all documents relating to the said Stock, but so that no such provision be inconsistent with Paragraph A of this resolution.*"

PATENT

SILICIUM BRONZE AND SILICIUM COPPER WIRE.

The best for overhead Telephone and Telegraph Lines,

AND ALL ELECTRICAL PURPOSES.

Hard Drawn High Conductivity Copper Wire.

ROLLED AND DRAWN PHOSPHOR BRONZE.

PHOSPHOR BRONZE BEARINGS, BUSHES, AND OTHER PARTS OF ELECTRICAL MACHINERY.

*SOLE PROPRIETORS of the British, Indian and Colonial Patents,*

THE PHOSPHOR BRONZE COMPANY (Limited),

*87, Sumner Street, Southwark, London, S.E.*

WIRE AND SHEET MILLS: BAGOT STREET, BIRMINGHAM.

The SECRETARY (Mr. F. E. Hesse) having read the notice convening the meeting, as above,

The CHAIRMAN said: Gentlemen, you have heard the resolution read, and I think I had better say, in two words, that the object of this proposal is to enable us to replace the £320,000 of Six per Cent. Debentures by an issue of Four per Cent. Debenture Stock. That is the real object, and, as I stated at the general meeting on the 22nd inst., will effect a saving to the Company of over £6,000 a year. Without further remark, I beg to propose the confirmation of this resolution, which you have heard read.

The Marquis of TWEEDDALE seconded the motion.

The CHAIRMAN: I shall be glad to answer any questions that may be put to me.

Mr. J. LEWIS asked when the money for the new Mortgage Debenture stock would be required.

The CHAIRMAN: What we propose to do is to receive 5 per cent. on application, 5 per cent. on allotment, and 90 per cent. on the 15th of January. The 1st of February is the day on which we are obliged to have the money ready to redeem the Six per Cent. Bonds, so that we have carried over the bulk of this amount to January.

Mr. LEWIS: When will the first payment be made?

The CHAIRMAN: The probability is that we shall make the issue so as to get the two first payments of 5 per cent. in December, in order that we may have all the arrangements ready by the following month. He then put the resolution, which was carried unanimously. Continuing, he said: This is an unfortunate time, but I think we may congratulate ourselves that during all this crisis—and probably such a crisis has never previously occurred in London—our stocks have not varied ½ per cent. That is a very remarkable feature, showing very great confidence so far as our shareholders are concerned. Our shareholders are not great people, but, generally speaking, have small comfortable homes, and look for their dividends regularly, and know, in the case of these companies, that they will come when due. I think I may repeat what I have before told you. In travelling from my place in the country I met a gentleman and his wife, and the wife said to me, "We like your Companies, because your dividends are always so regular"—referring to the Eastern and the Eastern Extension Companies. Now, that is a very nice position to hold. The circular inviting subscriptions from the shareholders for the new Mortgage Debenture Stock will be sent out immediately. We made a promise to the shareholders to give them the option of taking this stock, though I may say that some of the old debenture-holders are putting in claims for a renewal of their holdings. We tell them that they have had 6 per cent. for a great many years. However, we shall deal with the matter as fairly as we can.

Mr. LEWIS proposed a vote of thanks to the Chairman, whom he congratulated on his hopeful tone.

Mr. WILLIAM WOOD seconded the motion, which was carried unanimously.

The CHAIRMAN: I am much obliged to you, gentlemen. It is Dickens who said that there was no credit in being jolly in good times, but that credit was due to him if he could be jolly in hard times.

The meeting then separated.

## Swan United Electric Light Company (Limited).

The following is the eighth annual report of the Directors, to be presented at the ordinary general meeting of the Company, to be held at the Cannon-street Hotel, London, on Tuesday, the 25th inst., at twelve noon. After paying all current charges, and making due allowance for depreciation, there is a credit balance of £44,477. 15s. 10d. The Directors recommend that out of this balance a dividend of ten per cent. for the year be declared; an interim dividend at the rate of six per cent. per annum, amounting to £11,104. 0s. 5d., has already been paid in respect to the first half of the year; the balance of the ten per cent. for the entire year to be distributed in accordance with Clause 77 of the Articles of Association, and to be payable on December 1st next. This will absorb £24,921. 17s. 7d., and leave £8,451. 17s. 10d. to be carried forward. The decision in the patent suit in Germany was given in favour of this Company in the Court of Appeal in Berlin during the summer. The Allgemeine Electricitäts Gesellschaft have appealed from that decision to the Supreme Court at Leipsic. It is expected that the case will be heard and finally decided before Christmas. The Compagnie Générale des Lampes Incandescentes in Paris have not yet been able to obtain a decision in the Courts on the validity of their French patents, but they think that the case will be reached and a decision given during next spring. Their business is increasing, but the competition which they have to sustain compels them to sell lamps at a lower price than heretofore. The Directors who retire by rotation are F. R. Leyland, Esq., and W. C. Quilter, Esq., M.P., who, being eligible, will offer themselves for re-election. Messrs. Welton, Jones and Co., the auditors, will also retire, and will offer themselves for re-election.

## CITY NOTES, &c.

**BANKRUPTS.**—Wednesday's *Gazette* announces that a receiving order has been issued in respect of John William Horace Gray, St. Augustine's-road, Camden Town, and Albert Gray (the said A. Gray trading on his own separate account as W. Gordon), Wellington-road and Staines-road, Twickenham, and Piccadilly, florist, trading in partnership as J. W. Gray and Son, Leadenhall-street, City, and Prince of Wales-road, Plaistow, engineers.

**BRAZILIAN SUBMARINE TELEGRAPH COMPANY.**—The receipts of this Company for the week ended November 14th amounted to £5,249.

**THE EASTERN AND SOUTH AFRICAN TELEGRAPH COMPANY.**—Notice is given of the drawing of 298 Five per Cent. Mortgage Debentures of £100 sterling each in the above Company. These will be paid at par on January 1st next by Messrs. Barclay, Bevan, and Co., of 54, Lombard-street, E.C. The numbers of the Debentures will be found in our advertisement column.

**ELECTRIC CONSTRUCTION CORPORATION.**—Subject to final audit, the Directors of this Corporation have decided to declare a dividend of 6 per cent. per annum upon the ordinary share capital of the Corporation for the past year.

**FOREIGN AND COLONIAL ELMORE PATENT COPPER DEPOSITING COMPANY.**—The Directors of this Company have issued a circular to the shareholders in which they state that, after subscribing for £50,000 debenture stock in the French Company, there remains a sufficient sum to pay a cash dividend of £5 per priority share, and the Directors now declare an interim dividend of £4 per share, payable on December 8th next.—The transfer books of this Company will be closed from December 1 to December 8 (inclusive), for the purpose of paying a Dividend.

**STOCK EXCHANGE.**—Application has been made to the Committee to allow the following security to be quoted in the Official List:—Eastern and South African Telegraph Company (Limited), £201,600 Four per Cent. Mortgage Debentures.

**RICHARD HORNSBY AND SONS (LIMITED).**—The Directors have declared the following dividends:—On Preference stock, at the rate of 6 per cent. per annum, for the half-year ending December 14th; on ordinary shares, 5s. 6d. per share, for the half-year ending September 30, 1890, making, with the interim dividend paid June 14th, 8s. 3d. for the year on the £7 paid.

**TAUNTON, DELMARD, LANE, AND CO. (LIMITED).**—A meeting of the shareholders of this Company was held on Wednesday, at Birmingham, at which resolutions to effect the voluntary winding-up of the Company were passed, Mr. A. H. Gibson being appointed liquidator, with a committee of inspection, consisting of three creditors and two shareholders' representatives.

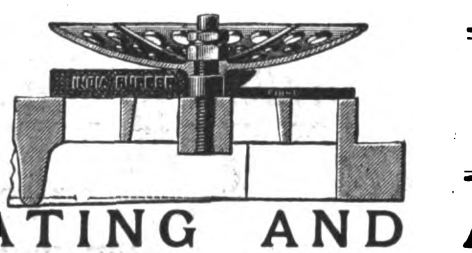
**WENHAM COMPANY (LIMITED).**—The Directors have declared a Dividend of 5 per cent., making 7½ per cent. for the year.

**WESTERN AND BRAZILIAN TELEGRAPH COMPANY.**—The traffic receipts of this Company for the week ending November 14, 1890, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited) were £4,087.

**WEST INDIA AND PANAMA TELEGRAPH COMPANY (LIMITED).**—The estimated traffic receipts for the half-month ended Nov. 15th were £2,571, against £2,878 in the corresponding period of 1889.

NEW VALVE

No Rubber, Percha, or Leather.



One-half the price of Rubber or Metal.

FOR CIRCULATING AND AIR PUMPS.

Unaffected by any Lubricating Oils. Does not Expand in diameter. Feed Water may be worked at any temperature Suitable for any shaped guards. Only one quality manufactured.

"12, John-street, Sunderland, 20th Sept. 1888.

"DEAR SIRS,—In reply to your letter of the 25th inst., the Valves I got from you have done their work well, and ARE AN UNQUALIFIED SUCCESS. I will continue to get them from you as required.—Yours faithfully, JAMES WESTOLL."

For further Testimony and Prices, apply to MOSSES & MITCHELL, 68-71, Chiswell Street, London.

# THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

## ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 654.—Vol. XXVI. FRIDAY, NOVEMBER 28, 1890. Price Fourpence.

## NOTES.

If a brilliant reception, followed next evening by an equally successful banquet, can compensate for the labour they entail, the President of the Institution of Electrical Engineers may congratulate himself on having signalised his year of office in an altogether satisfactory manner. The attendance at the former was unusually numerous, and the speeches at the latter were exceptionally encouraging, showing as they did the profound and intelligent interest taken in the welfare of the Institution, even by public men removed from the sphere of its professional influence. Much is evidently expected of it, and the present is regarded as a critical moment in the affairs of electrical science and industry.

A sample of the cable which has been made in accordance with the Board of Trade Regulations has been kindly sent us by Mr. Crompton, together with a sample of a "medium" pattern which is offered as a compromise, and which it is suggested should not be exceeded, and a sample of an ordinary cable which experience has shown to be thoroughly suitable for the purpose. We have prepared some illustrations, which will be found on another page, in order to give our readers some idea of the result of designing a cable with the paternal motive of "the protection of the public safety," and of prescribing the adoption of it without ever seeing a sample. The description of the insulation is as follows: "A thickness of not less than one-tenth part of an inch, and in cases where the extreme difference of potential in the circuit exceeds 2,000 volts, the thickness of insulation must not be less in inches, or parts of an inch, than the number obtained by dividing the number expressing the volts by 20,000. This insulation must be further efficiently protected on the outside against injury or removal by abrasion." This verbal description does not at first sight appear to be preposterous, and it was solemnly approved by a committee of the Council of the Institution of Electrical Engineers who saw neither a drawing nor a sample. If an illustration had been submitted, it is probable that, although there were only two engineers among them, some objection would have been raised: but the ridiculous character of the cable can only be judged by handling a sample.

Mr. Crompton strenuously opposed the rule, but he could hardly be expected to stand up against the Board of Trade and win the case off his own bat. The Electrical Trades Section of the London Chamber of Commerce addressed a letter to the Board of Trade without avail. Experiments were carried out at Chelmsford by Major Cardew with the cables proposed by Mr. Crompton, and to those who were present the results appeared striking enough to convince the scientific adviser to the Board that the proposed modifications were of a reasonable character, but they were grievously disappointed to find that the Board of Trade declined to yield, and that no relaxation would be permitted. The Council of the London Chamber of Commerce have now taken up the matter as being one of general trade importance, and we hope that their influence, together with the memorials of the four principal companies who are interested in the matter, will succeed in obtaining a compromise, both in the insulation of aerial cables and of the rule relating to bearers.

The two cases reported in our "Legal Intelligence" this week both turn on the absence of any written agreement between the supply company and the consumer. The one case, however, was won by the former, the other by the latter. It was no doubt very annoying to the well-known firm of drapers in Regent-street to have their light cut off without notice, even though it was being supplied on sufferance by a company who had no powers in that district; but, in pleading that "the gas injured the stock, and made the premises dirty," that "their goods became greatly damaged," and that to the absence of the electric light they attributed a "serious effect" on their business and goods, they give an admirable "unsolicited testimonial" to the benefits of the illuminant with whose purveyors they have quarrelled. They had neglected to agree to the form of contract which had been sent to them by the defendant company, and the result should be a warning to those who are relying on verbal arrangements for their supply.

The second case discloses two points of interest. First, the price per annum for a 10 candle-power lamp, the charge of £1 being said by the counsel for the plaintiff company to be "considerably under the market value of the current supplied;" second, the fact that after a meter has been fixed, the consumer declined to pay, presumably, because the charge was higher than before. We do not hear that the instrument was accused of that inherent prevarication which an experience of three-quarters of a century has attributed to the gas meter. A simple calculation shows that at 7¼d. per unit, a supply of about 1,000 lamp-hours of a 32 watt lamp may be purchased for £1. This is equiva-

Digitized by Google

lent to lighting from dusk until 9 p.m. all the year round, and since, we may presume, that the members of the Pall Mall Club do not retire to rest at this hour, the assertion of the counsel was well founded. In the lighting of a club, nearly the whole of the lamps are in use every night, and a contract for such a supply might be based with tolerable accuracy on a table of the hours of lighting, due allowance being made, from experience, for fogs. The lighting of dwelling-houses is of course of another character, and we have somewhat contradictory information on this point. The earning power of each lamp wired is very different in different localities, depending, as it does, not only on the proportion of the lamps wired to the maximum number in use at any time, and the mean number of lamp-hours per day, but also on the manners and customs of the consumers.

Among the numerous mathematical processes devised expressly for the investigation of physical phenomena, there is, perhaps, none the value of which to the physicist in general, and to the electrician in particular, is so misunderstood as that due to the genius of Laplace, and to which the name of Spherical Harmonic Analysis has been given by Sir William Thomson. To the physicist or electrician of moderate mathematical attainments, the very name Spherical Harmonic acts as a sort of scarecrow, recalling to his mind only a difficult chapter of Maxwell, or a still more difficult one in Thomson and Tait's great treatise. The treatment of the subject in the latter work is indeed quite beyond the comprehension of any but advanced mathematical students, and even to the majority of these it is difficult. Ferrer's excellent little treatise on the subject is unfortunately as yet almost unknown except to the professedly mathematical student, though it is by no means difficult, and would be easily apprehended by many who are needlessly frightened at the name.

For these reasons we would direct the attention of our mathematically-inclined readers to Professor Perry's recent communication on this subject to the Physical Society, of which an abstract appears in another column. Professor Perry has, in the first place, drawn up a table which we hope he will be able to extend considerably, of the numerical values of the Zonal Harmonics of the first few degrees. The Zonal Harmonic is the simplest and at the same time the most useful of the functions known as Spherical Harmonics, as it is the form applicable to all problems in which the conditions are symmetrical about an axis. It is a function merely of the angle made by the radius-vector of a point with this axis, and Professor Perry has calculated the values to four place of decimals for each angular degree from 0 to 90 degrees. The table even in its present restricted form will be of the greatest value to all who find occasion for making calculations with these functions, and we hope the author will see his way to having them introduced into some of the books of logarithmic and other mathematical tables in common use. The tabulation of these functions will enable them to be used in calculations as easily as the trigonometrical functions of angles; and if this is insufficient to make the name Spherical Harmonic no longer a kind of bogie to the practical electrician, we have the further interesting and most pertinent fact that Professor Perry has so completely succeeded in making the elements of Spherical Harmonic Analysis comprehensible to the classes of students at the Technical College, Finsbury, that they are not only interested in it, but perfectly able to make use of it in obtaining numerical solutions of numerous problems of importance to the electrical engineer.

The word of caution which will be found in our correspondence columns with regard to magnetic materials in laboratories is worthy of attention, and to the unsuspected cause of variations of temperature of pipes and stoves may be attributed the unaccountable behaviour of magnets which is often observed during delicate investigations. Permanent magnets are generally sufficient to control the terrestrial magnetism in the neighbourhood of a given point; but if it were desired to neutralise the greater part of a room, it would only be necessary to run a wire or cable two or three dozen times round the room in a plane perpendicular to the dip, and through it pass a current, giving a few hundred ampere turns.

**The British Guiana Cable.**—The cable between Trinidad and Demerara is at present interrupted.

**Correction.**—On page 75 of our last issue, after the word product, on the fifth line, the words "of a current" were accidentally omitted.

**The Electro-Harmonic Society.**—The next concert (Ladies' Night) of this Society will take place on Monday, December 8th, instead of, as is customary, on a Friday.

**International Telegraph Bureau.**—Dr. Rothen, hitherto Director of Swiss Telegraphs, has been appointed Director of the International Telegraph Bureau at Berne, in the place of the late M. Frei.

**Llanelly.**—It was unanimously decided at the last meeting of the Local Board that an application be made to the Board of Trade for an order authorising the Board to supply electricity for public or private purposes within the area of their district.

**Electrical Trades Union.**—All members are urgently requested to attend headquarters on Saturday, November 29th, at eight p.m., for the purpose of electing and instructing the delegates for the forthcoming convention to be held in Liverpool, on December 6th.

**University College, Dundee.**—In consequence of Prof. Ewing's election to the chair of engineering at this College, the Professorship of Mechanism and Applied Mechanics in Cambridge University will shortly be vacant. Further particulars will be found in our advertisement columns.

**The Patten Multiplex Telegraph.**—We hear that the multiplex telegraph devised by Lieutenant Patten, a description of which appeared in *The Electrician* of August 22, 1890, is working 16 circuits on a wire running between New York and Philadelphia, a distance of about 90 miles, at twenty-five words a minute.

**Reduction of Telephone Rentals.**—It is announced that the annual rate of subscription to the Bradford Exchange of the National Telephone Company will be reduced on and after New Year's Day from £15 to £10 for a connection within one mile of the Exchange. The trunk line tariff will also be revised at the same time.

**Frankfort Exhibition.**—Our German Correspondent informs us that the storms of Monday last greatly injured the machinery hall of the Frankfort Exhibition. The hall was of solid construction, and completed up to the cupola. Nobody was hurt. The contractor hopes to have repaired the damage done within four weeks.

Digitized by Google

**The Paris Electricity Meter Competition.**—The Conseil Municipal have nominated MM. Mascart, Potier, Hospitalier, Cochin, and Lyon-Alemand as members of the jury which is to examine the electricity meters sent in to compete for the municipal prize of £400 offered for the meter "giving complete satisfaction and equally applicable to alternate or continuous currents."

**National Telephone Electrical Society.** — The first meeting of the session of the Midland Branch of this society was held at Birmingham, on Friday evening last, when the president, Mr. Coleman, M.I.E.E., delivered an interesting address on "Telephony at the Present Time." There was a large attendance, members from Derby, Coventry, Kidderminster, Walsall, and Wolverhampton being present.

**Telephonic Appointment.**—Mr. A. R. Bennett, whose resignation from the National Telephone Company we had occasion to chronicle in August, has accepted a three-years' engagement with the Mutual Telephone Company as their general manager and chief engineer. We understand that Mr. Bennett, whose headquarters will be in London, has reserved the right to practise also as a consulting engineer and electrician.

**Glasgow Tramway Company.**—A petition was recently presented to the Court of Session, Edinburgh, by the Glasgow Tramway Company for sanction to an alteration of its Memorandum of Association, to the extent of allowing it to carry on omnibus traffic, carry mails, work the cars by electricity or steam, and to increase its capital by £150,000. Intimation to the magistrates of Glasgow was ordered, and answers in eight days.

**Glasgow and West of Scotland Technical College.**—The gold medal for electrical engineering presented annually by Sir John Pender, K.C.M.G., through Prof. Jamieson, to the Glasgow and West of Scotland Technical College, has been gained by Arthur H. Allen, who, besides taking the first place in all his College classes, took the first place with first class honours at the Science and Arts public examinations, and first class honours at the City and Guilds of London Institute technological examinations.

**New Telegraph Line between Berlin and Rome.**—Telegraphic communication between Germany and Italy is to be improved by the construction of a third line between the two capitals. The line will pass through Bavaria and the Tyrol, instead of through Switzerland, as the existing lines do. Its length will be 1,210 miles, and it will consist of 3mm. bronze wire. According to the *Elektrotechnische Zeitschrift*, this is the first line from Germany to any foreign country in which bronze wire has been employed.

**Glasgow.**—By the instruction of the Corporation Special Committee on Electric Lighting, Mr. Foulis, the Gas Manager-in-Chief, has just compiled a report on data which he has collected regarding about 40 electric lighting undertakings throughout the kingdom—both corporation and company concerns; and it is expected that the committee, at their next meeting, will take some further action, based on the report, and on the "expert" report which was obtained from Mr. R. E. Crompton some months since.

**Madrid.**—On Saturday night, during a performance at the Comedia Theatre, Madrid, before a full house, an alarm of fire was raised, and almost immediately the theatre was in complete darkness. It was, however, found that the fire was confined to part of the wings of the stage, and was of little importance, and the audience vacated the theatre quietly and without accident. The origin of the fire appears to have been the accidental short-circuiting of two imperfectly-covered wires, causing them to ignite some light canvas in the side scenes.

**Electric Light Mains in Paris.**—At a recent meeting of the Conseil Municipal four of the electric light companies petitioned for the prolongation of their concessions to 1930. The petitions were referred to a Committee. A member of the Conseil then asked that the companies should be requested to suspend their underground main laying operations until after the New Year, and was informed that the usual regulations suspending such work from December 15th to January 15th would be enforced. It was also intimated that measures had been taken to oblige the companies to carry out their operations in future in a more methodical manner.

**Australian Cable Rates.**—The Government of Victoria has decided to propose to the Legislature the adoption of the cable guarantee required by the telegraph companies to enable them to put into force the projected reduction of rates. The Government of Western Australia has likewise agreed to take similar action. It is also probable that New South Wales and South Australia will join in the guarantee. It is now the prevalent opinion here that the reduced rate will be brought into force from the commencement of next year, irrespective of the fact that the colonies of Queensland and New Zealand have declined to bear their share.

**Ice on Trolley Wires.**—With a view of preventing the adhesion of any considerable amount of sleet or ice to trolley wires, a Mr. Whittlesey, of Lynn, Mass., proposes to grease the conductor. The apparatus consists of a pan attached to the ends of the journal of the trolley itself. Inside the receptacle is a wheel. This grooved wheel is made of wood or hard rubber, and is covered with thick felt, so as to be adapted to carry up and smear upon the wire against which it presses the contents of the pan. When a semi-liquid substance is used for coating the conductor, an endless belt or chain may be passed over the wheel to assist in carrying up the grease.

**Electrical Testing Stations.**—At the last meeting of the London County Council, the Highways Committee recommended, and it was agreed, that the Parliamentary Committee be instructed to insert in the Council's General Powers Bill of next Session a clause giving the Council power to require any Electric Lighting Company to supply electrical energy to the Council's electrical testing stations, even if the station for which the supply is required be beyond the limits of the company's area of supply, and authorising such company, subject to the usual notices, to break up streets for the purpose of laying the mains necessary to afford such supply to the testing stations.

**Lagging for Steam-pipes.**—According to the *Revue Industrielle*, some of the waste products resulting from the manufacture of paper furnish excellent material for cheap and efficient lagging for steam-pipes. The waste products in question are chiefly those coming from the different cleaning and sorting machines, and which are of a fibrous nature. These, when dry, are to be mixed with potter's earth in the proportion of four to one, enough water being afterwards added to form a plastic compound. This is spread by hand over the surfaces to be protected in thin successive layers. When dry, the coating is said to adhere firmly, and is not easily broken. Its cost is practically no more than the cost of mixing and applying it.

**City and South London Railway.**—A number of trains, each consisting of an electric locomotive and three carriages, have been running regularly for some days on this railway in order to educate the staff in the working of the electrical plant, the hydraulic lifts, and other matters which are peculiar to the undertaking. It is expected that the final inspection of the Board of Trade will take place within a few days, and that the line will then be open to the public. On Monday, the 24th inst., Prince Hermann of Saxe-Weimar privately visited the railway. We understand that the announcement that the trains would commence running on this line on the 26th inst. was entirely unauthorised, and that no date has as yet been fixed.

**Agglomerate for Leclanche Cells.**—The *Bulletin International de l'Electricité* gives the following recipe for the manufacture of agglomerate for use in Leclanché cells:—

| | |
|---|---|
| Binoxide of manganese ... ... ... | 40 per cent. |
| Graphite ... ... ... ... ... ... | 44 ,, |
| Tar ... ... ... ... ... ... ... | 9 ,, |
| Sulphur ... ... ... ... ... ... | ·6 ,, |
| Water... ... ... ... ... ... ... | ·4 ,, |

This mixture must be reduced to fine powder, then compressed and heated to about 350° C. The heating drives out the water and most of the tar. Some of the sulphur combines with the volatile products of distillation, and the rest combines with non-volatile residue.

**Edinburgh Exhibition.**—At a recent meeting of the Finance Committee of the Dundee Town Council letters were read from the liquidator for the Edinburgh International Exhibition and the agents of the British Linen Company Bank, each claiming payment of the £200 which the Corporation agreed to subscribe towards the guarantee fund of the exhibition. The committee, in view of the whole circumstances, resolved to object to the Corporation being included in the list of contributors. It is understood that the foreign exhibitors are about to raise an action against the Exhibition Association to ordain the latter to deliver diplomas and medals awarded to them. They hold that medals in gold, silver, and bronze, as well as diplomas, were promised, but have not been given.

**City and Guilds of London Institute.**—The prizes gained by the students of the City and Guilds of London Institute were distributed by Lord Cross, at the Clothworkers' Hall, on Wednesday evening. The Lord Mayor presided, and among those present were Sir F. Bramwell, Sir S. Waterlow, Sir F. Abel, Sir P. Magnus, Prof. Unwin, and Prof. Thompson. Lord Cross having handed the prizes to the winners, said that the Clothworkers' Company had not been behindhand in furthering the question of technical education, for so long back as 1783 there was a conference called in that hall on the subject. Last year upwards of 12,000 students, mostly artizans, were taken into classes under the auspices of the City and Guilds of London Institute, and of these 6,000 presented themselves for examination and nearly 3,000 passed. He congratulated the Institution upon the exertions it had made.

**Safety Device for Overhead Wires.**—A simple but ingenious safety device has been brought out in America to immediately earth any overhead wire that may break, and thus render it harmless. It is principally intended to be used in connection with trolley wires, but it can, of course, be applied to any electrical wire. The device consists of a length of wire, one end of which is attached to the pole and thence to earth, and the other end to the trolley conductor. The wire is divided in the middle and enclosed in a weather-proof box, flat discs being fixed to the divided ends, which are kept apart by the tension of the wire. Should the trolley conductor snap, a strong spring inside the box causes the flat discs to come in contact and thus place the line to earth. Some such contrivance is apparently much needed in the States, where accidents due to persons coming into contact with the ends of live wires are frequently occurring.

**Royal Society.**—The anniversary meeting of the Royal Society will this year be held on Monday, December 1st. The medals are to be given as follows:—The Copley Medal to Prof. Simon Newcomb, for his contributions to gravitational astronomy; the Rumford Medal to Prof. Heinrich Hertz, for his work on electro-magnetic radiation; a Royal Medal to Prof. David Ferrier, for his researches on the localisation of cerebral functions; and a Royal Medal to Dr. John Hopkinson, for his researches in magnetism and electricity; the Davy Medal to Prof. Emil Fischer, for his discoveries in organic chemistry; and the first Darwin Medal to Mr. A. R. Wallace, for his independent origination of the theory of the origin of species by natural selection. The anniversary dinner will take place at the Hotel Métropole.—Among the Papers down for reading yesterday before the Royal Society was one by Messrs. G. J. Burch and V. H. Veley on "The Variations of Electromotive Force of Cells consisting of Certain Metals, Platinum, and Nitric Acid."

**A Charge Indicator for Accumulators.**—At a recent meeting of the Société Internationale des Électriciens, M. Gaston Roux described a form of direct-reading charge indicator devised by him for use with accumulators. The apparatus is based on the fact that within certain limits the density of the electrolyte varies according to the quantity of electricity stored in a storage cell in a chemical form. Experiments carried out by M. Roux show that the temperature correction is entirely negligible between 0°C. and 30°C. M. Roux employs a long cylinder reaching nearly to the bottom of the cell in order to take into account the want of homogeneity of the liquid. This cylinder is hung from the end of the short arm of a small lever, which should be horizontal when the cell is fully charged. On the same axis as the lever, and on the same side as the cylinder, there is arranged at an angle of 45deg. with the lever a small rod, along which a small weight can be screwed. On the long arm of the lever there is also an adjustable weight. At right angles to the lever there is a long pointer moving over an equally-divided scale. When the cell is discharged to its working zero, the pointer is brought to the scale zero by adjusting the weight on the long arm of the lever. When the cell is fully charged the pointer is brought to 100 by adjusting the weight on the rod fixed at 45deg. with the lever. The instrument being thus adjusted for a particular cell the percentage state of charge of that cell at any moment is seen from the position on the scale occupied by the pointer. An instrument such as this should prove of considerable use in an isolated installation, where a storage battery is left in the hands of an unskilled attendant.

**New Cable.**—The laying of the Great Northern Telegraph Company's new cable between Newcastle and Gothenburg, which was begun on the 16th inst., was successfully completed on Saturday last, and the cable was immediately opened for correspondence. This new cable has been manufactured by the Telegraph Construction and Maintenance Company, and is about 550 miles long, and will bring the number of telegraph cables landed by the Great Northern Company on our shores up to five. Of these the one between Scotland and Norway is landed at Peterhead, and worked from the Great Northern Station at Aberdeen, while the remaining four are landed at Newbiggin, and worked from the Company's station at Newcastle. The development undergone during the last 20 years by the traffic passing through Newcastle becomes apparent when comparing the number of telegrams exchanged with the Scandinavian countries in 1889 as against 1869. In 1889 there were sent to Denmark 156,000 telegrams, as against 28,000 in 1869; to Sweden 155,000, as against 24,000 in 1869; and to Norway 188,000, as against 33,000 in 1869. In spite of this great increase of work the Company has managed to reduce the time of transmission to about one-fourth of what it used to be. Messages from Copenhagen now reach the Quayside within one hour after they have been handed in at Copenhagen. The laying of the new North Sea Cable is the more commendable when it is borne in mind that at the late Telegraph Conference at Paris the Company agreed to reduce their rates to Denmark and Norway by ½d., and to Sweden and Russia by 1d. per word, although only four years ago, at the Berlin Conference, the rate to Russia was reduced from 9d. to 6½d., making a total reduction of about 50 per cent. within five years.

**Magnetic Rocks and Ships' Compasses.**—The following extract from a letter of Profs. Rücker and Thorpe, which appeared in *The Times* of Friday last, may be of interest:—

As it has been suggested that the loss of Her Majesty's ship Serpent may have been due to a deviation of the compass caused by magnetic rocks, we think your readers should be warned that such an explanation should only be accepted after rigorous proof. In the first place, it must be borne in mind that ordinary iron-stone is not magnetic. Metallic iron and the magnetic oxide are practically the only substances which could affect the compass to an appreciable extent. Large disturbances generally occur in the neighbourhood of basalts, gabros, and the like, throughout which magnetite is scattered in a more or less finely divided state. Such rocks are plentiful on the west coast of Scotland, and on the island of Canna there is a cliff named Compass Hill from the great effect which it produces on the magnet. . . . We have made a special study of the magnetic properties of this island, and can confirm the statement that its basaltic cliffs are powerfully magnetic. The needle of a compass placed near them may be deviated by two points. The effect, however, diminishes very rapidly with the distance, and is inappreciable on a ship's compass 200 yards from the base of the hill to which tradition ascribes, and in which we have ourselves detected, the most powerful magnetic properties. We have tested this on more than one occasion. In particular, in 1889, we approached the island from the north. The course was magnetic S. ½ E., a direction most favourable for the detection of the effect of Compass Hill. We passed it within 200 yards of the shore, but observed no effect on the compass. . . . . . Nowhere in the United Kingdom have we discovered a disturbance which extends for a mile, and also produces throughout that distance a constant deviation of the compass of as much as a couple of degrees. While, therefore, it is difficult to assign any limit to what might occur in an extraordinary and special case, and while we believe that there are some well-authenticated instances of magnetic rocks affecting seriously the compasses of ships in their immediate neighbourhood, the greatest caution ought to be exercised in accepting any such instance as proved. It is contrary to general experience that intense local magnetic disturbances should also be far-reaching.

## MAGNETISM IN IRON AND OTHER METALS.*—XXXVI.

BY PROF. J. A. EWING, F.R.S.

(*Continued from page 77.*)

§ 129. **Influence of Vibration on the Effects of Stress.**—These indications of hysteresis disappear almost entirely if we submit the piece under test to mechanical vibration either during or after the changes of load. As modified by vibration the curves for loading and unloading become nearly coincident. The whole amount of magnetic change is increased. A maximum point is still found, which lies, as regards load, between the two maximums that are observed when the processes are gone through without vibration. Tapping the wire at any stage in the process produces, in general, a large change in its magnetism; but if loading or unloading is then resumed, without further tapping, the presence of hysteresis is at once conspicuous. Fig. 111 illustrates the influence of vibration, by showing the curves got by repeated loading and unloading of an iron wire, suspended in a weak magnetic field, first without vibration, and also with smart vibration before each reading of the magnetometer was taken.

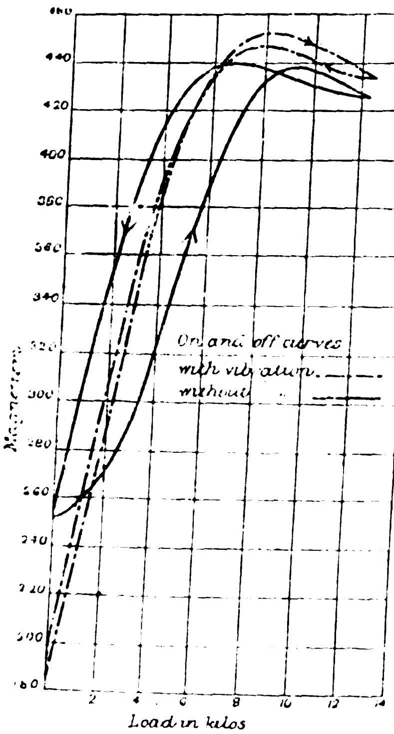

FIG. 111.—Influence of Vibration on Effects of Loading and Unloading

§ 130. **Effects of Loading Annealed Iron.**—On applying loads to an annealed iron wire, hanging in a magnetic field, we find at first the same extreme sensitiveness, the result of molecular instability. Repetition of the loading, if repeated often enough, brings about a cyclic state in which there is much less total change of magnetism than is found in the corresponding experiment with hardened metal. As to the character of the change, it depends on the magnitude of the load. With a sufficiently light load, loading produces increase and unloading produces decrease of magnetism; with a moderately heavy load these effects are reversed.†

§ 131. **Effects of Longitudinal Stress in Cobalt.**—Sir W. Thomson, testing a cobalt bar hung vertically in the earth's magnetic field, found that pulling decreased and relaxing the pull increased the induced magnetism. The effects of longitudinal pressure on the magnetisation of cobalt have been examined by Mr. C. Chree,* who found a reversal of effect, as the magnetisation was increased, resembling the Villari reversal in iron, but *opposite* to it in character. In iron, as we have already seen, after the first effects of stress are past, pressure will reduce magnetism in weak fields, but will increase it in strong fields. In cobalt the reverse happens; pressure increases magnetism in weak fields, but reduces magnetism in strong fields. This may be shown either by magnetising when the pressure is on, and again when it is off, or by applying and removing pressure while a constant magnetising force is in action. If the latter plan is followed, we have, of course, to exclude the initial effects, which, as Mr. Chree has pointed out, occur in cobalt as they occur in iron. The first application of pressure in weak fields causes a large increase of induced magnetism, just as, we may anticipate, the first application or removal of stress of any kind would do; but repetition of the process soon establishes a cyclic state.

The effects of longitudinal pressure in modifying the magnetisation curve of cobalt are illustrated in Fig. 112 (from an experiment by the writer and Mr. W. Low). The full lines are two curves of induced magnetism for a rod of cast cobalt, tested within a yoke without stress, and also with a comprehensive stress amounting to 16·2 kilogrammes per square millimetre. The broken lines are the corresponding curves of residual magnetism. The induced curves cross, illustrating the reversal described by Mr. Chree. The residual curves do not cross within the limits of field used here; but other experiments, made with the same rod but with heavier loads, show a crossing in them also. Curves of the permeability in terms of **B**, drawn from the data of the same experiment, have already been given in Fig. 42, § 76.

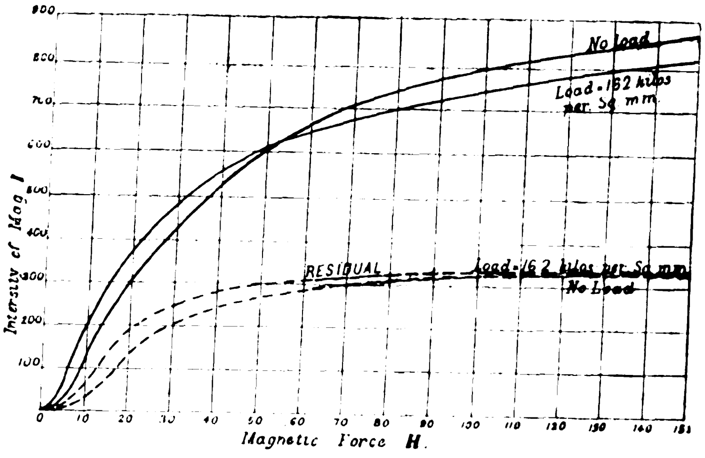

FIG. 112.—Induced and Residual Magnetisation of Cobalt with and without Compressive Stress.

§ 132. **Relation between the Effects of Stress on Magnetism, and the Effects of Magnetism in Changing the Dimensions of Magnetic Metals.**—In his book on "Applications of Mathematics to Physics and Chemistry" (p. 47, *et seq.*), Prof. J. J. Thomson has discussed this subject, and has pointed out that it is possible, from theoretical considerations, to predict the general character of the effects of stress from a knowledge of the changes of dimension caused by magnetisation. Mr. Shelford Bidwell, in a Paper which will be referred to later in more detail†, has shown that an iron rod lengthens when it is magnetised, provided the magnetising force does not exceed a certain limit, but shortens if the force does exceed that limit. Prof. Thomson shows that this reversal of effect is to be anticipated from the Villari reversal which is observed in the effects of longitudinal stress. Again, a nickel rod shortens when magnetised, and continues to shorten under high magnetic forces; this agrees with the fact that in nickel there is no Villari reversal, and that longitudinal pull diminishes the magnetism, whether that is weak or strong. Again, with cobalt Bidwell has found from

* All rights are reserved.

† For examples of the curves got by loading and unloading annealed iron see *Phil. Trans.*, 1885, plates 62 and 64. Many of the effects of stress, both in annealed and in hardened metal, will be found exhibited there, by means of curves, more completely than it is possible to exhibit them here. A few examples of the effects of *compressive* stress on the curves of I and H for iron will be found in a paper in the *Phil. Mag.* for September, 1888. The presence of compressive stress lowers the curve, as might be anticipated from the raising of it by tensile stress, shown in Figs. 103 and 105.

† *Phil. Trans.*, 1888, A, p. 205.

Digitized by Google

effects opposite to those found in iron, namely, that weak magnetisation shortens a cobalt rod and strong magnetisation lengthens it. Applying his equations to this result, Prof. Thomson anticipates what the character of the effects of stress in cobalt should be. Mr. Chree's experiments have verified his conclusions, by showing that the effects of stress in cobalt are the reverse of the effects of stress in iron, tension diminishing weak magnetism but augmenting strong magnetism.*

§ 133. **Residual Effects of Stress applied before Magnetising.**—Perhaps the most interesting of all the effects of stress are those that occur in unmagnetised iron. To apply and remove load before beginning to magnetise a piece of iron has been found to affect the magnetic susceptibility, even when the load is well within the elastic limit, and when the piece is perfectly free from magnetisation during application and removal of the load. We have, in fact, evidence that even in unmagnetised iron the process of loading and unloading causes changes of molecular configuration which are not reversible. These changes exhibit hysteresis with regard to the loads which cause them. They affect more than one physical quality of the metal; in particular, they produce an effect upon the magnetic susceptibility which becomes obvious when the piece is magnetised. These residual effects of past loads may be wiped out by subjecting the piece to the operation of demagnetising by reversals. They may also be wholly, or almost wholly, removed by tapping the piece smartly and so causing vibration.

Hence, in experiments designed to show the difference in susceptibility of iron or steel when subjected to different amounts of load, the piece should be passed through the operation of demagnetising by reversals after the load has been put on. This procedure was, in fact, followed in the experiments that have been described above.

The residual effects of these, occurring in the absence of any actual magnetisation, are of very great interest in their bearing on any theory of the molecular constitution of magnetic metals. One or two experiments may be cited to show their general character.†

Let an iron wire be subjected to pulling stress, and let the load be removed before beginning to magnetise. Then, provided the load which has been applied lies within the elastic limit, or is less than some load by which the wire has been previously stretched, we observe no mechanical change of any ordinary kind as the result of applying and removing the load. And if, before beginning to take a curve of magnetisation, we put the wire through the process of demagnetising by reversals, we shall find nothing in the curve to show whether there has or has not been any application of load before that. But suppose, after the process of demagnetising has been gone through, we apply and remove some load before beginning to magnetise. Though there has been no immediately obvious mechanical change, the wire has undergone a change of structure which shows itself in the form assumed by the curve of magnetisation. We find the magnetic susceptibility, especially under low forces, much greater in this than in the former case. The whole difference in procedure may be no more than this, that in one case the load is removed before the process of demagnetising is performed; in the other case, the process of demagnetising is performed before the load is removed. So slight a difference in procedure might, perhaps, be expected to have no influence on the form of the curve; in fact, however, it has a large influence. The curve of magnetisation depends not merely on the load actually present: it is affected, especially in its early portion, by any changes of load which have taken place since the preceding demagnetisation. For instance, it has been observed that if a curve be taken with (say) a pull of 3 kilos. on an iron wire, and if, after complete demagnetisation, the load be raised to 4 kilos. and 1 kilo. be removed, and a second curve be then taken, the second curve will differ very sensibly from the first, in spite of the fact that the wire may have previously held many times that amount of load, and was, therefore, in a mechanically stable state.

## DRUM ARMATURE WINDING.

BY F. M. WEYMOUTH.

*(Continued from page 73.)*

In Figs. 10 and 11 we find the method adopted by Edison of placing insulated metal discs *a a* at each end of the core, and of the same number at each end as there are segments in the commutator, and of the same outside diameter as the core. A few of the parallel bars only are shown. The two bars of a coil would thus at the pulley end be connected to the approximately opposite edges

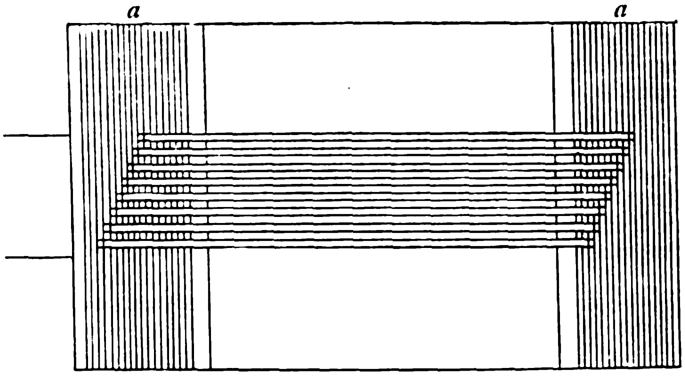

Fig. 10.

of the same insulated disc, while at the commutator end they would be jointed to separate discs. Fig. 11 shows one of these discs. A hole through the middle serves for the passage of the spindle and ventilation, and a tongue *b* shown across it, cut through at one end, is bent outwards parallel with the spindle for connection with a commutator segment. The four smaller holes *c c* are for the passage of insulated screws running parallel with the spindle by which the whole set of discs at one end are bolted to the end plate of the core.

This arrangement has the advantage of being compact, and has all the joints on the outside and accessible. Hence any burnt or damaged bars can easily be renewed singly without disturbing the remainder. By making the discs rather stout in proportion to the current they have to carry, their

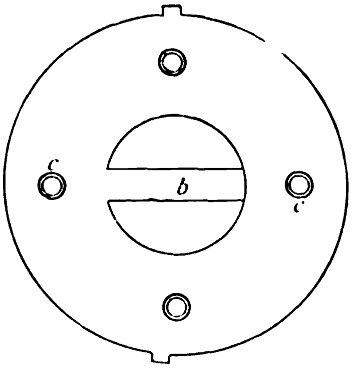

Fig. 11.

resistance can be kept low, and the tendency to heat obviated, rendering their ventilation not so necessary. The discs, however, are liable to the disadvantage of having a maximum difference of potential between any two that are adjacent; and will thus require more care as to their insulation from each other. A drawback, however, to using round discs is that these have to be stamped or cut out from sheet metal, involving waste of metal, beside extra cost in labour and use of machinery. It is a point as to whether or not this cost is counterbalanced by subsequent facility of construction. It will be noted that the bars are straight, and have no bends; but in both designs, however, as shown in Figs. 9 and 10, it will be observed that these are solid, and are liable to heat with Foucault currents.

The next example we may take is Messrs. Crompton and Swinburne's evolute end winding. This, as illustrated in

Digitized by Google

Figs. 12 to 17, will be seen to differ entirely from the foregoing. Fig. 12 represents an end view of the armature, Fig. 13 a longitudinal section, and Fig. 14 an outside elevation, all diagrammatic, and with a very open winding for the sake of clearness. It will be noted that alternate parallel bars run the full length of the armature, and are united to the commutator

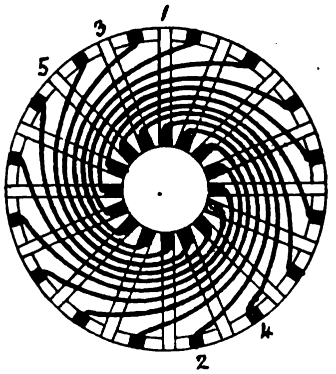

Fig. 12.—Crompton-Swinburne Winding. End view of Armature.

lugs at one end. The remaining bars are short, at least as to their straight portions, and we will for convenience call them so. A "long" bar and a "short" one opposite thus form the two sides of a coil. In Fig. 13 it will be seen that the short bars are cranked inwards towards the shaft, as shown at *a a*. At *b b* are sections through the evolute connections formed of

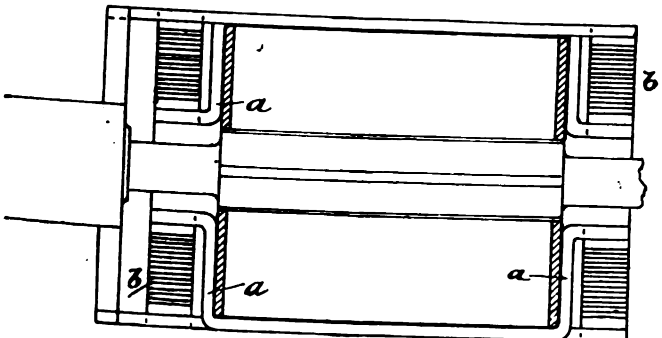

Fig. 13.—Crompton-Swinburne Winding. Longitudinal Section.

thin pliable copper strips, indicated more clearly in the end view, Fig. 12. Each of these, jointed at its interior end to the crank of a short bar is carried round in an evolute path till it reaches the desired long bar on the approximately opposite side, and there is jointed to it. Thus, referring to Fig. 12, the short bar 1 is connected by an evolute strip jointed to its cranked

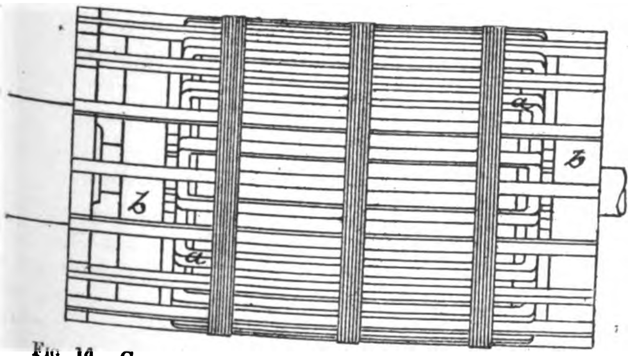

Fig. 14.—Crompton-Swinburne Winding. Outside Elevation.

end to long bar 2 opposite; this, at the other end of the armature, is similarly connected to bar 3, and 3 again to 4, and 4 to 5, and so on all round. It will be noted how the evolute connectors lie neatly within each other, though in practice they fit closely, separated only by mica or other insulation.

In the arrangement, however, as here shown, the cranked conductors, if burnt, cannot be removed without dismounting the whole winding, or a great part of it. Hence the modification shown (Fig. 15), where the crank is separately jointed to the turned-up end of the "short" bar, as indicated at *f*. By unsoldering these joints *f*, and also the joints *g* between the "long" bars and the evolute connectors, any single parallel bar can be removed. Further, by withdrawing the spindle (which can be done if the coil is carried on a spider, or otherwise self-contained apart from the spindle), the loose crank piece can be drawn in radially, its joint with the interior end of its connector unmade, when both can be removed singly. Thus any one, or a few sections, can be replaced without dismounting the remainder. The total number of joints is, however, increased. It will be noted that these bars are here

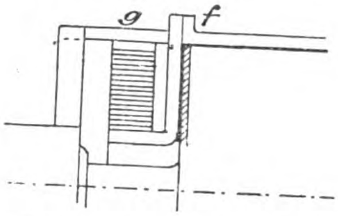

Fig. 15.—Crompton-Swinburne Winding.

all solid, and when single can only be used for small currents. For large currents double bars are used, as already described in connection with Figs. 4 to 7. In Fig. 16 is shown a modification to gain more room for the evolute connectors, the long bars being slightly cranked outwards. Thus far we have dealt

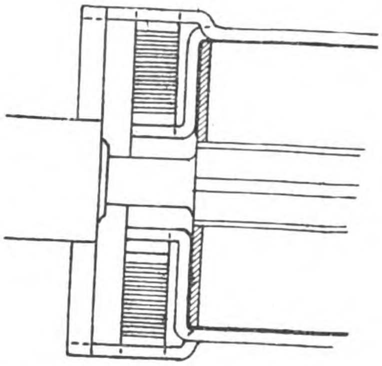

Fig. 16.—Crompton-Swinburne Winding.

with but a single turn per section. In Fig. 17 is shown the arrangement for two turns per section. It will be seen that there are two parallel series of evolutes; also, the cranks are alternately long and short to suit. In this case the connectors may be narrower and thicker than in the former arrangement; thus in the total mass there will be more copper and less

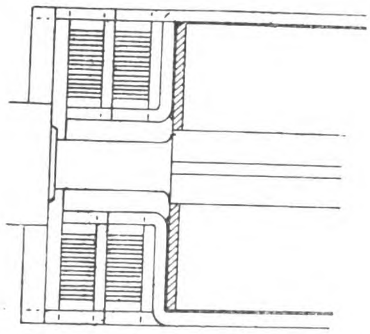

Fig. 17.—Crompton-Swinburne Winding.

insulation than when the curved plates are thin; and so space is economised. The spindle within the core is either of triangular or square section, with slightly rounded angles. The core is carried tight on the angles, its interior bore being grooved to fit these, and ventilation is thus allowed for along the flats. Sometimes a spider is used to carry the core, instead of its being built on the shaft direct.

## NOTES ON THE CHEMISTRY OF SECONDARY CELLS.*

By Professor W. E. Ayrton, Vice-President; C. G. Lamb, B.Sc., and E. W. Smith, Associates.

I.

In our paper on "The Working Efficiency of Secondary Cells," read at the meeting of this Institution in Edinburgh in July, it was stated that, "In spite of accumulators with actual accumulator plates in action. We are therefore now, with the assistance of Mr. Robertson, making a complete investigation of the chemical state of the plugs of both the positive and negative plates at all stages of the charge and discharge of an 1888 E.P.S. type of accumulator in good condition." The present paper contains an account of the results thus obtained.

The cell selected to remove the plugs from had the same size as the cells employed in the investigations described in the previous communication, and was one of the batch of 50

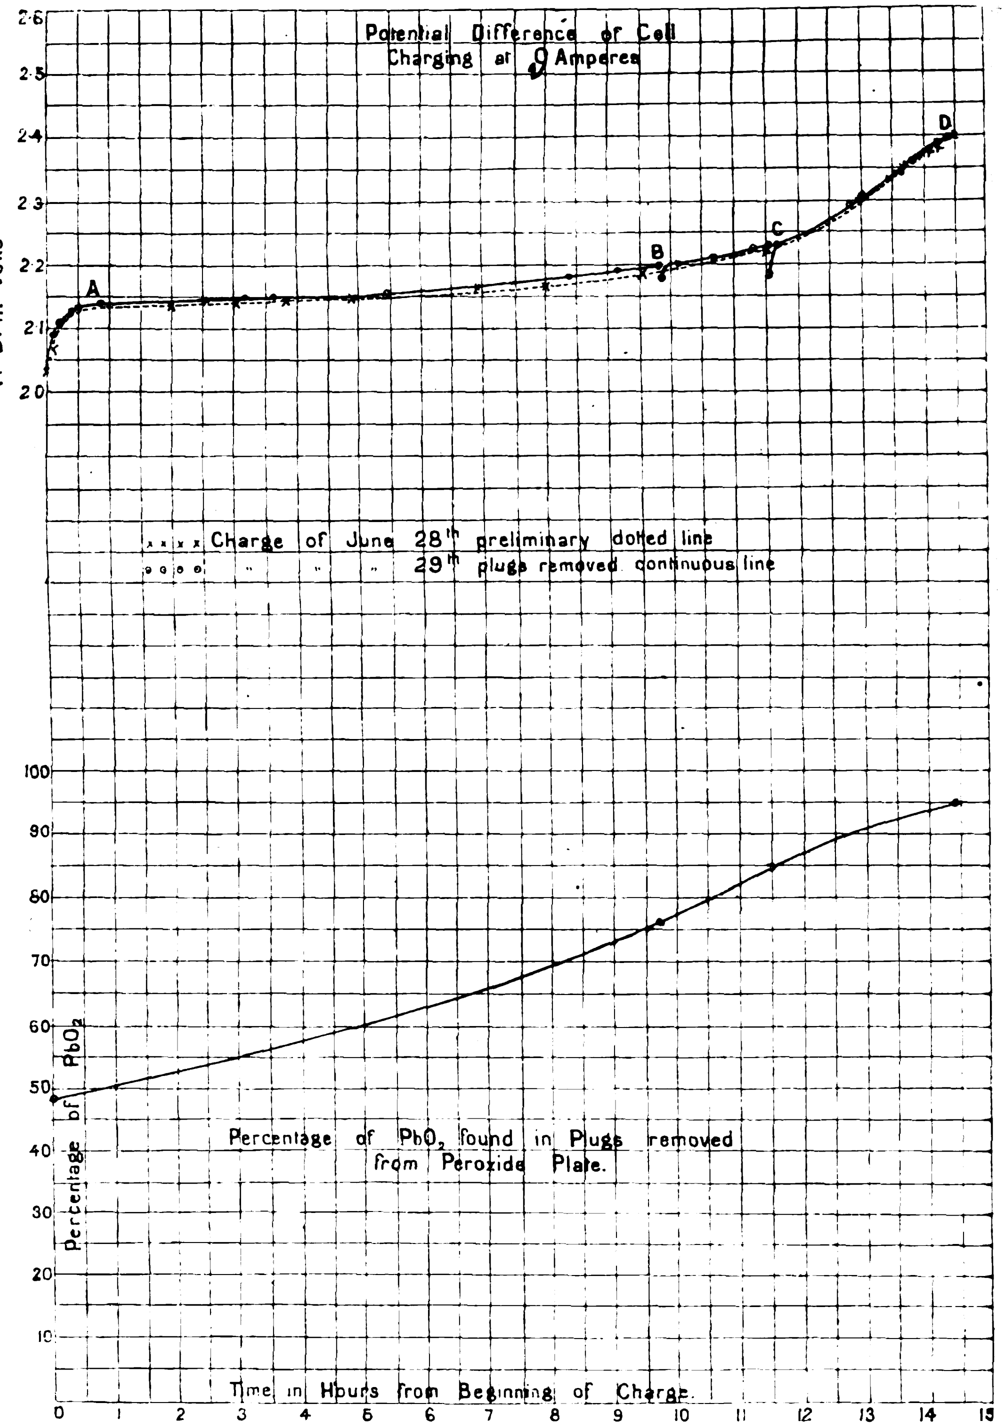

Fig. 1.

pasted plates having been in use now for nine years, the chemical action that takes place during the different stages of the charge and discharge has only been conjectured, and, odd as it seems, no decisive experiment appears to have been made to settle this much-debated question. Various analyses have been made by different chemists of salts of lead acted on in certain ways with sulphuric acid, but apparently not of purchased for the Central Institution about the middle of 1888. Since it first came into our possession it had never been overcharged, never been left discharged, nor permitted to send more than the maximum current allowed by the makers for cells of this size—viz., 10 amperes—and consequently, at the beginning of the present investigation in June of this year, this cell was in excellent condition.

First, the cell was several times charged with a current of 9 amperes, and discharged with a current of 10, without stopping

* Paper read before the Institution of Electrical Engineers on Thursday, November 13, 1890.

Digitized by Google

day or night, so as to bring it into what we have called its steady "working" state. The dotted curves, Figs. 1 and 2, show the large charge and discharge obtained on June 28th. During the next charge, indicated by the continuous curve, Fig. 1, plugs were removed from both the positive and the negative plates at the points marked A, B, C, and D, when the terminal potential difference of the cell was 2·134, 2·2, 2·234, and 2·4 volts respectively. In order to remove the plugs from the positive plates, these plates were bodily removed out of the liquid, but, to prevent oxidation, the negative plates were left on the curve; that is to say, the potential difference observed immediately after replacing the positive plates in the liquid and closing the circuit is plotted directly under the potential difference that was observed just before the circuit was broken, prior to the removal of the positive plates from the liquid.

We were afraid that the bodily withdrawal of the positive plates out of the liquid, combined with the removal of the plugs on the several occasions, would produce so great a change in the conditions of the cell as to render the potential difference curve quite discontinuous. It was, therefore, as interesting as

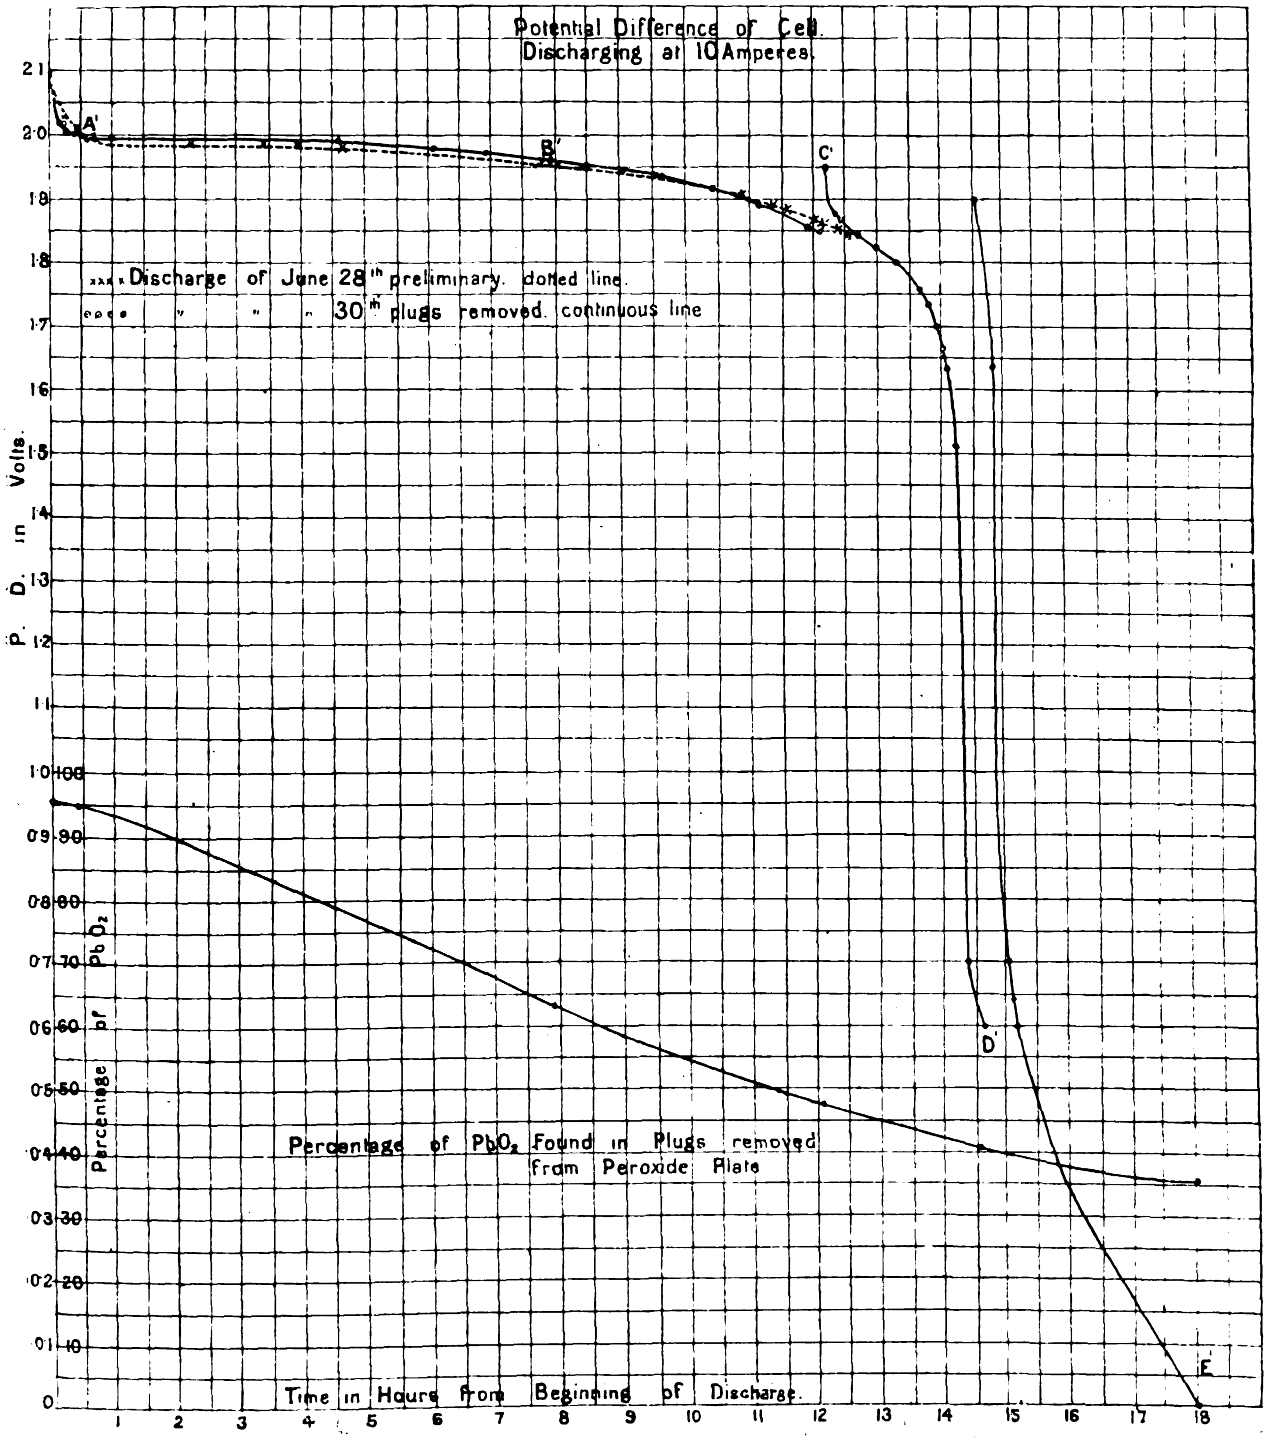

Fig 2.

in the liquid, and the plugs removed in a way that will be described later on. The time occupied in removing the plugs from the two sets of plates occupied about 15 to 20 minutes on each occasion. Immediately after the removal of the plugs the positive plates were put back in position in the cell, the resistance in the circuit rapidly adjusted, if necessary, to make the charging current exactly 9 amperes and the time variation of the potential difference at the terminals of the cell noted. The interval that elapsed while the current was broken is not shown it was unexpected to find that the terminal potential difference, on restarting the normal charging current of 9 amperes, rapidly acquired the value it had before the withdrawal of the plates; so that, with the exception of the rapid rise of the potential difference on restarting the charging current, the potential difference curve obtained on June 29th was almost the same as the potential difference curve obtained on charging on the previous day.

After the cell had been charged until the terminal potential difference reached 2·4 volts, it was immediately discharged with

a perfectly constant current of 10 amperes, and, as it was anticipated that the removal of the plugs would spoil the cell, it was allowed to discharge far below the normal limit. In previous discharges (the last one of which is shown by the dotted line, Fig. 2), the discharge was stopped when the terminal potential difference fell to 1·85 volts. But in the discharge on June 30th, when the plugs were removed the discharge current was kept at 10 amperes, by using auxiliary cells, until the E.M.F. of the test cell fell to nought, and even reversed. Plugs were removed from both the positive and the negative plates when the terminal potential difference was 2, 1·95, 1·85, 0·6, and nought volts, as indicated by the points A′, B′, C′, D′, and E′. The recovery of the E.M.F. on breaking the circuit was very marked, especially near the end of the discharge.

II.—Method of Obtaining Samples of the Plugs.

On the first removal of plugs corresponding with the point A (Fig. 1), a curved pointed glass rod was used, as shown in Fig. 3, with the idea of prising out the plugs; but by this method only the surface of the positive plugs could be removed, as they were much too hard to be loosened in this way. Indeed, one of the most striking things noticed in this investigation was the firm way in which the plugs were held in the plates of an E.P.S. cell that had been carefully used for two years. Before the next attempt was made to remove plugs corresponding with the

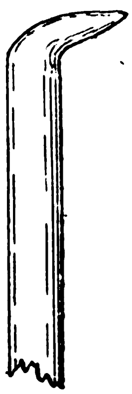

Fig. 3.

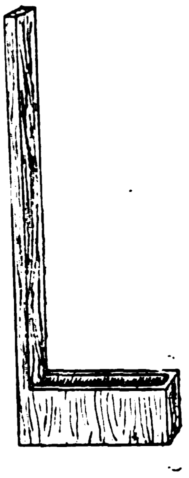

Fig. 4.

point B (Fig. 1), a straight piece of glass rod was pointed, and mounted in a wooden handle. This glass chisel was used to pierce and loosen the positive plugs, which were then driven bodily out of the grid by means of a hard wooden punch cut square to fit the holes in the grid, and which was tapped with a small mallet. The plugs on being driven out of the grid were caught in a long wooden scoop (shaped so that it could be just slipped in between the plates), and then washed by Mr. Robertson into wide-mouthed bottles containing 300 or 400 cubic centimetres of distilled water. As soon as the water cleared it was decanted off and fresh added.

As several glass chisels were broken, and the wooden punches worn down in the removal of the plugs, the method had the disadvantage of mixing with the specimens to be analysed splinters of glass and wood, which were found difficult to remove afterwards. On the other hand, the method had the advantage of enabling specimens of the positive plugs to be removed in a comparatively short time on each occasion from the top, the middle, and the bottom of the plates.

As the negative plates were never removed from the acid, the only way to remove the plugs was by working them loose under the liquid by means of long curved glass rods pointed at the end, and by catching the plugs in a narrow wooden scoop with a long handle, as shown in Fig. 4. It was possible to use this method throughout for the removal of the negative plugs, as they were softer and more easily removable than the positive ones. The scoop held sufficient liquid to enable the negative plugs to be dropped into wide-necked bottles containing water without the plugs being even momentarily exposed to the air. The water in these bottles Mr. Robertson had washed free from dissolved oxygen by previously bubbling hydrogen through it for a considerable time. After the negative plugs had been put into the bottles the water was gradually decanted off from time to time, and fresh added until the liquid in the bottle was quite free from acid.

Both in the case of the positives and the negatives the top samples were removed from the corner of the plates nearest the lug, and the bottom samples from the corner diametrically opposite, so as to obtain evidence, if possible, of any difference of current-density which might exist at different parts of the plates in charging and discharging.

The plugs from the top, the middle, and the bottom of each set of plates were at each of the removals of plugs put into six separate bottles, and, to avoid the possibility of error in their subsequent identification, there was noted on the label of each the character of the plates and the position on them from which the plugs were removed, the time, the potential difference, and the specific gravity of the liquid in the cell.

III.—Appearance of Plates at Removals of Plugs.

The following notes were made by Mr. Robertson and ourselves at the successive removals of the plugs:—

*Charging.*

| Positive Plates. | Negative Plates. |
|---|---|
| *Point A on Curve 1. Terminal Potential Difference,* 2·134 *volts. Specific Gravity of Liquid,* 1·178. | |
| The upper part of the plates had a greyish-brown colour, and presented the appearance of being coated with a very thin film of white sulphate. The lower part of the plates was of a reddish-brown colour. The plugs at the top were hard, while those at the bottom were quite soft. | The plugs at the top were the softest. |
| *Point B on Curve 1. Terminal Potential Difference,* 2·2 *volts. Specific Gravity of Liquid,* 1·198. | |
| The plates had entirely lost their whitish appearance, and showed a uniform reddish-brown colour, darker than the previous colour of the bottom of the plates. | The plugs both at the top and at the bottom harder than before, those at the top having hardened more than those at the bottom. |
| *Point C on Curve 1. Terminal Potential Difference,* 2·234 *volts. Specific Gravity of Liquid,* 1·201. | |
| The previous charges increased in amount. | The previous charges increased in amount. |
| *Point D on Curve 1. Terminal Potential Difference,* 2·4 *volts. Specific Gravity of Liquid* 1·206. | |
| The plates had the rich deep brown colour of lead peroxide, except where they were covered with the ebonite separators: there the colour was lighter. The plugs at the top were slightly the softest, while those at the bottom were much the same as at the beginning. | The plugs had a brilliant metallic lustre, and looked quite silvery when first removed from the plates. The plugs at the top were now the hardest. |

*Discharging.*

| Positive Plates. | Negative Plates. |
|---|---|
| *Point A′ on Curve 2. Terminal Potential Difference,* 1·998 *volts. Specific Gravity of Liquid,* 1·205. | |
| The plugs at the top were harder than those at the bottom. | The plugs had the brilliant metallic lustre observed at the end of the charging. |
| *Point C′ on Curve 2. Terminal Potential Difference,* 1·850 *volts. Specific Gravity of Liquid,* 1·180. | |
| The plugs had become much harder. | The plates had become decidedly white, and the plugs were white right through. |
| *Point D′ on Curve 2. Terminal Potential Difference,* 0·6 *volt. Specific Gravity of Liquid,* 1·175. | |
| The plugs had become extremely hard, especially at the bottom. | The plugs were somewhat softer. |
| *Point E′ on Curve 2. Terminal Potential Difference,* 0 *volt. Specific Gravity of Liquid,* 1·172. | |
| The plugs had become so hard that they splintered, and bits flew about on trying to remove them. | |

Digitized by Google

The bubbling of gas from the negative plates ceased when the terminal potential difference on discharging fell to 1·85 volts (point C′ on curve 2), and it began again when the terminal potential difference fell to somewhere near zero.

The following figures (5 and 6) give an idea of the way in which we found the hardness of the top and bottom plugs of the positive and the negative plates respectively to vary during a normal charge. The figures are not drawn to scale, as we had no standard of hardness beyond our sensations, hence the figures only profess to be qualitative sketches from which mental pictures can be obtained. Distance measured upways from O A indicates roughly the degree of hardness; distance measured downwards the degree of softness.

It will be seen that during the charging the variation in the hardness of the plugs is far greater at the top than at the bottom of the plates, and consistently with this fact Mr. Robertson's analyses show that, on the whole, the rate of chemical action at the top of the plates is greater than at the bottom. The difference in the hardness, however, is far more marked than the difference in the chemical action. For example, while the plugs

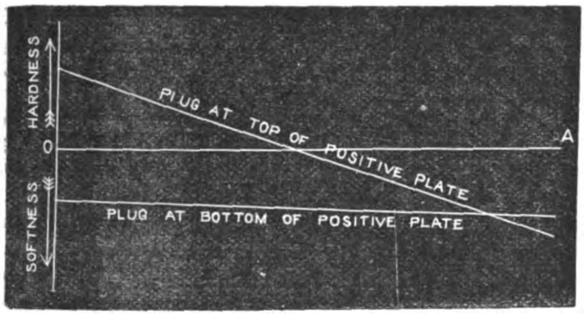

Fig. 5.

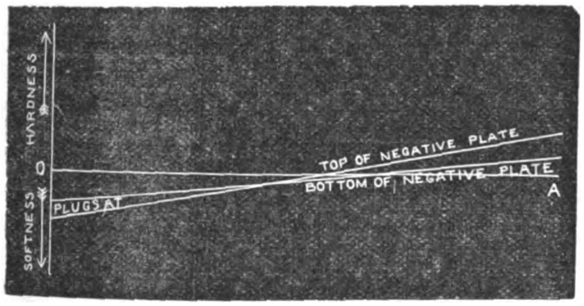

Fig. 6.

at the top of the positive plates are, during the earlier part of the charging, much harder than those at the bottom, no such striking difference is observable in the percentage of lead peroxide contained by these plugs. The cause of this we are examining experimentally at the present time.

*(To be continued.)*

## ON THE USE OF THE LANTERN IN CLASS-ROOM WORK.*

BY PROFS. BARR AND W. STROUD.

Prof. Barr described a lantern with inclined mirrors for projection of horizontal slides on which experiments could be performed on a small scale; and he described the practice of sketching on oiled ground glass.

At the Yorkshire College, Leeds, photographic lantern slides are used very extensively in teaching many different subjects. An assistant is employed in making slides, and 50 slides are frequently made per week. A very complete apparatus was exhibited for making slides from book and other illustrations. A frame or open box was arranged with a flat top. The book being opened, the page, on which is the illustration required, hangs down, while the other is laid face downwards on the top of the frame; the page thus lies quite flat. The camera is mounted on a slide on a long board, provided with a scale. The numbers on the scale, while arbitrarily denoting the distance of the camera from the picture to be copied, refer to the longest actual dimension of the illustration in inches. The body of the camera is also provided with a scale graduated similarly, and so arranged that when the pointers are adjusted to the same numbers the object is accurately focussed, without the use of a ground glass screen, and the image is exactly the right size for a lantern slide. The camera was mounted in a very ingenious manner on two pair of hinged boards, arranged at right angles and disposed similarly to the first pair of folds of a camera bellows on two adjacent sides. The parallel motion is excellently adapted for the purpose. One of the hinges is provided with a spiral spring, which approximately balances the camera at any height.

Such an apparatus has been in use for some time at the Yorkshire College, Leeds, and has led to a great development in the application of the lantern in class-room work; so much so, that not only in the science classes and the technical classes but even in the classes of classics, geography, and others the lantern is utilised.

* Abstract of Paper read before the British Association in Section A, Leeds, September, 1890.

DISCUSSION.

Dr. OLIVER LODGE said that he was much struck with the beauty of the arrangement which had been described. His practice was never to darken the room when using a lantern for projection. He used a very translucent screen of oiled silk one yard square. Being small, the disc was strongly illuminated. Light falling on the screen from in front does no harm; the audience may be in a good light; any stray light from behind is bad. He thought that experiments with the reflecting arrangement were not advisable.

Prof. BARRETT thought that more attention should be paid to the light. He had tried specially-made glow lamps with close-coiled filaments. These required 10 to 20 amperes, but emitted a great deal of heat. He much preferred a modification of a Werdermann lamp giving a very small arc. It had two slender carbons almost touching. It required three or four amperes. With this lamp he could use a microscope slide mounted with Canada balsam, and it would not be injured by ten minutes' exposure without an alum cell.

Prof. BARR, in reply, said that he preferred an opaque screen about five feet square for an audience of about 100 persons. He thought a small transparent screen was not suitable for an audience of such a size, and besides, with such a screen the lantern could not be conveniently worked by the lecturer himself, which he considered a very important point. Arrangements were being made with a large maker of cameras for the manufacture of the complete apparatus, which he hoped would be obtainable from any dealer.

## MEETINGS OF SCIENTIFIC SOCIETIES, &c.

**FRIDAY, November 28th.**

PHYSICAL SOCIETY.

*5 p.m.* Papers to be read: "Notes on Secondary Batteries," by Dr. GLADSTONE and W. HIBBERT; "An Illustration of Ewing's Theory of Induced Magnetism," by Prof. S. P. THOMPSON, D.Sc.

**MONDAY, December 1st.**

ROYAL INSTITUTION.

*5 p.m.* General Monthly Meeting.

SOCIETY OF ENGINEERS.

*7.30 p.m.* Ordinary Meeting. Paper to be read: "On Ship Caissons for Dock Basins and Dry Docks," by J. J. F. ANDREWS.

SOCIETY OF ARTS.

*8 p.m.* Cantor Lecture I. 2. "Gaseous Illuminants," by Prof. VIVIAN B. LEWES.

ROYAL MICROSCOPICAL SOCIETY.

*8 p.m.* Conversazione.

**TUESDAY, December 2nd.**

INSTITUTION OF CIVIL ENGINEERS.

*8 p.m.* Ordinary Meeting. Paper to be further discussed: "The Vibratory Movements of Locomotives," by Prof. JOHN MILNE, F.R.S., and JOHN McDONALD. Papers to be read, time permitting: 1. "The Sukkur Bridge at Benares," by F. E. ROBERTSON, M.I.C.E.; 2. "The New Chittravati Bridge, Madras Railway," by E. W. STONEY, M.I.C.E.

ROYAL VICTORIA HALL.

*8.30 p.m.* Lecture: "Rocks seen through a Microscope," by E. WETHERED.

**WEDNESDAY, December 3rd.**

SOCIETY OF ARTS.

*8 p.m.* Ordinary Meeting. Paper to be read: "The Chicago Exhibition, 1893," by JAMES DREDGE.

**THURSDAY, December 4th.**

CHEMICAL SOCIETY.

*8 p.m.* Ballot. Paper to be read: "On the Volumetric Estimation of Tellurium," by G. D. BRANNER.

Digitized by Google

# The Electrician.

**Published every Friday, Price Fourpence; Post Free, Fourpence Halfpenny.**
**Editorial, Publishing, and Printing Offices:**
**SALISBURY COURT, FLEET ST., LONDON, E.C.**
*Telephone No.* 2714. *Telegrams:* "ELECTRICIAN NEWSPAPER, LONDON."

*All Letters relating to Subscriptions, Advertisements and other business matters should be addressed to the Publisher,* "THE ELECTRICIAN," *Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* "THE ELECTRICIAN" *Printing and Publishing Company, Limited, and be crossed* "*Coutts and Co.*" *All other letters to be addressed to the Editor.*

*All letters intended for insertion in* "THE ELECTRICIAN," *or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever will be taken of anonymous communications.*

"THE ELECTRICIAN" *is published every Friday morning, in time for the morning mails. Subscribers should receive their copies by the first post on Friday morning.*

"THE ELECTRICIAN" *is on sale at the railway bookstalls throughout the Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices as above.*

*New Volumes of* "THE ELECTRICIAN" *commence in May and November.*

## SUBSCRIPTION RATES.

The rates for Subscriptions to "THE ELECTRICIAN" are as follows :—

| | 3 months. s. d. | 6 months. s. d. | 12 months. s. d. |
|---|---|---|---|
| For the United Kingdom | 5 0 | 10 0 | 19 6 |
| For Foreign Parts and Colonies :— | | | |
| Within Postal Union | 6 6 | 12 6 | 24 0 |
| Aden Borneo, Ceylon, China, India, Japan, Java, Labuan, Mozambique, New Caledonia, Persia, Philippine Islands, Siam, Transvaal, and Zanzibar | 7 6 | 14 6 | 28 0 |

## TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has by far the largest circulation of any English Electrical paper, and circulates all over the World.**

*Particulars relating to Advertisements will be promptly forwarded on application to the Offices as above.*

TRADE ADVERTISEMENTS *intended for the current issue must reach the Offices not later than First Post on Thursday morning. Renewals of expiring advertisement orders and alterations to standing advertisements should be in the Publisher's hands by Wednesday at latest. No alteration can be made in Wrapper advertisements after Wednesday evening.*

SMALL PREPAID ADVERTISEMENTS *(for Rates see page xvii.) are accepted up to 4 p.m. on Thursday.*

## TECHNICAL PRINTING.

"THE ELECTRICIAN" PRINTING AND PUBLISHING COMPANY (LIMITED) *inform Electricians, Electric Light Engineers, &c., that they make a specialty of Technical Printing, and have a large Staff thoroughly acquainted with Electro-Technology. They can, therefore, promise Accuracy and Despatch in the Printing of Electro-Technical Literature, &c.*

## "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. (Royal 8vo.)

*Early in each year is issued* "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. *The* DIRECTORY *was established in 1883, and the 1890 Edition consisted of about 850 pages of printed matter. The names and addresses of all persons engaged in the Electrical Industries at home and abroad may be relied upon as accurate. Useful Tables and Electrical Formulæ, and information specially compiled for this work are given, together with popularly-written Biographical Notices of the leading Electricians, Electrical Engineers, &c., accompanied in many cases by Portraits.*

*Orders for the 1890 issue should be forwarded* AT ONCE *to the Publishing Offices, Salisbury-court, Fleet-street, London, E.C.*

*The 1891 Edition is now preparing, and New Names, &c., can now be received.*

## ELECTRICAL BOOKS AND PUBLICATIONS.

***All Books, Newspapers, and other publications, dealing with Electrical and kindred subjects, can be ordered direct of* "THE ELECTRICIAN" *Printing and Publishing Company, who are proprietors of the well-known* "ELECTRICIAN" *Series of Standard Electrical Works, and are agents for all the leading publishing houses at home and abroad.***

## THE INTERCHANGE OF CENTRAL STATION STATISTICS.

If at this early stage of its existence the electric supply industry can so far sink the jealousy which too often accompanies healthy competition, and can act upon the scheme for exchange of statistical information which has been proposed by the Committee of the Electrical Trades Section of the London Chamber of Commerce, the economic administration will probably advance as rapidly as has the purely scientific construction. The two desiderata at the present time are a reliable continuous supply of electrical energy at a uniform prssure to the satisfaction of the consumer, and an equally reliable, continuous, but perhaps gradually increasing dividend for the gratification of the shareholder. The question of price need not concern us here. So long as the light is good, and the power, where motors are used, effectual, if sufficient demand be found to enable a fair return to be paid on the capital, it is of minor importance whether the relative prices of electricity and gas be widely different or approximately equal. There is no doubt whatever about the highly satisfactory supply of several of the London companies, and the question which remains to be settled is the profit which can be made by them. The excellence of the supply might have—though it certainly has not—been brought about by machinery, stations, and mains designed by a committee of the Royal Society. Fortunately there is plenty of sound engineering, and but little laboratory work to be found in our central stations. We have seen a small station in the provinces where an extremely ingenious manager had to make the best of a very antiquated lot of machinery, and was obliged to work the circuits upon an utterly obsolete system. The engine-room

Digitized by Google

was full of most remarkable devices of a home-made description, but of such complication that their clever inventor never dared to leave the place for a single night. Happily, our more important supply companies had the good fortune to come into existence at a time when electrical engineering had arrived at some maturity, and most of their work has been done deliberately, and in a sound manner. What would have happened if the electric lighting boom of 1882-3 had not been checked is fearful to contemplate. Many a supply station in America has been found to have been arranged upon lines which could not possibly pay, and new buildings and machinery have had to be erected. We, too, have had our failures. Colchester and Barnet have unfortunately not only been failures, but they have taught us no useful lesson. These, however, were primarily failures in the quality of the supply. Difficulties of that kind have been surmounted, and the next thing to look for is the dividend.

Until lately, the jealousy of competition has been excusable, and not to be wondered at. The alternating current system and the battery system have each found enthusiastic advocates, and these, citing what they meant to do rather than what had been done, found no temptation to prove the advantages of their systems by pointing to their balance-sheets, for, when the controversy was at its height, they had none to show. They are now offered a splendid opportunity of proving from experience the efficiency of their generating plant and that of their method of distribution. The engineers of each system are fully convinced that theirs is the best, and would not hesitate on such grounds to let others know what they are doing, For several years the sectional area of field magnets and of armature cores was the trade secret of each drawing office, but to-day no one cares to conceal such details, and the method of designing the essential parts of ordinary continuous current machines is common knowledge. Alternating machines are only now emerging from a similar stage, and transformers and their designs are still shrouded in that secrecy which to the inventor is an instinct, and to the manufacturer an obvious precaution. Outside the station we still find specialities in the form of patented systems of mains, but these are not for the most part likely to be of great importance, since up to the present it appears that a variety of unpatented methods give satisfactory results; at all events, there is no secrecy whatever. We have endeavoured to go over the grounds for any reluctance that may be expressed with regard to the structural or engineering part of the scheme for exchange of information, and in the present state of the industry, we cannot see why any supply company should hesitate to fill up and to return Table I. of the Chamber of Commerce circular given in our last issue. The exchange of such information will be of far greater use to the trade generally than a number of forms filled up by themselves would be to the individual engineers.

Coming now to the second table, which relates to costs, opposition may be raised by secretaries or managers who have to deal with the finance rather than with the machinery. But they should bear in mind that the information sought differs altogether from an inquiry into the books of a manufacturer. They are obliged by Act of Parliament to submit their accounts to the Board of Trade, and the actual cost of generating and of supply will have to be clearly stated. The total prime cost being thus disclosed, there should be no reluctance in allowing an analysis to be interchanged. Hitherto an additional reason for declining to publish prime costs of supply has been created by the fact that the local authorities are eager to acquire the electric supply business if they think that it is profitable. It is the careless and incapable vestryman especially who muddles away the money, and who welcomes anything which would "relieve the rates," when through his lack of administrative knowledge they have become a burden. But he will anxiously compare the total cost as stated in the Board of Trade form of accounts with the revenue earned by the company. Cost of fuel, and of superintendence per unit generated, will have no interest for him. The men who will value these returns the most are not only the secretary or manager, but the engineer also. The manager wants the cost reduced somehow, that a good dividend may be earned; and if he finds that a certain item of expenditure in his table of costs exceeds the average he will naturally attempt to reduce it. But to do this effectually he will have to appeal to the engineer. It will be for the engineer to investigate the reason, to remove the cause by improved arrangements, and thus to benefit his company in a way which would be impossible if his attention were not thus drawn to the matter.

An exchange of information as to cost of production has been undertaken by the Iron and Steel Institute, and has been readily responded to by ironmasters who were not obliged to disclose their profits: the information given by them, as Mr. Crompton has already pointed out, does not contain anything that would prematurely indicate the dividends, and the interchange has been of immense benefit to the iron and steel trade. There are several other matters which might with great advantage form the subject of interchange of information. Such are the proportions and degree of magnetisation of transformers to which we have already alluded, and the relative number of glow lamps sold at various voltages and candle-power. Unfortunately, it is considered by those who could give the information, that since they have little to gain by such publication, the undoubted advantage to the trade is not a sufficient inducement. The proposition before us presents no difficulty of this kind. The total cost must be published in the Board of Trade returns. The analysis would undoubtedly be of considerable value even to a manager who finds that he is doing as well or better than his neighbours, and the information which he gives after all only states the results, and does not in any way disclose the means by which he attains them.

## THE CENTRAL STATIONS OF THE METROPOLITAN ELECTRIC SUPPLY COMPANY.

BY DR. J. A. FLEMING, M.A.

*(Concluded from page 72.)*

We have next to notice the switch-board arrangements at Manchester-square. There are three switch-boards—one for the exciters, one for the dynamos, and one for the circuits. These boards are mounted on a partition which stands away from the wall of the dynamo room, and permits access to the connections behind the board. The working connections are mounted on enamelled slate bases, affixed to the wood frame of the switch-board. The dynamo switch-board is divided into ten panels corresponding to the ten dynamos. On each of these panels there is a main ammeter and ammeter short-circuiting plug, which reads the main primary current flowing out of each dynamo. There is also a Cardew voltmeter which reads the primary volts on one coil of the armature of each dynamo, and hence gives the total primary volts. Under each ammeter is a rheostat for introducing resistance into the field circuits of the dynamos, and thus regulating the electromotive force. At the bottom of each panel is a magnetic cut-out, the working arrangements of which

Digitized by Google

are shown in Fig. 15. The exciting current passes round the coils of the electro-magnets of this electro-magnetic cut-out. When the exciting current exceeds a certain safe value the attraction of an armature by this electro-magnet releases a double pole switch which is kept locked by a clutch and the switch springs back and opens the circuit of the fields. The exciter board

resembles a telephone switch-board. The object of the arrrangements is to group the exciters and dynamos. There are four exciters, one of which is sufficient for five dynamos. Hence at full load two exciters have to be operated. On the exciter board there are a series of vertical and horizontal bars which can be connected by plugs. The vertical bars are connected to the dynamo-field circuits, and the horizontal bars to the exciter poles. Hence by plugging together these strips any exciter can be put into the fields of any dynamo or dynamos arranged in parallel, and the exciters can be arranged so as to work in parallel on one

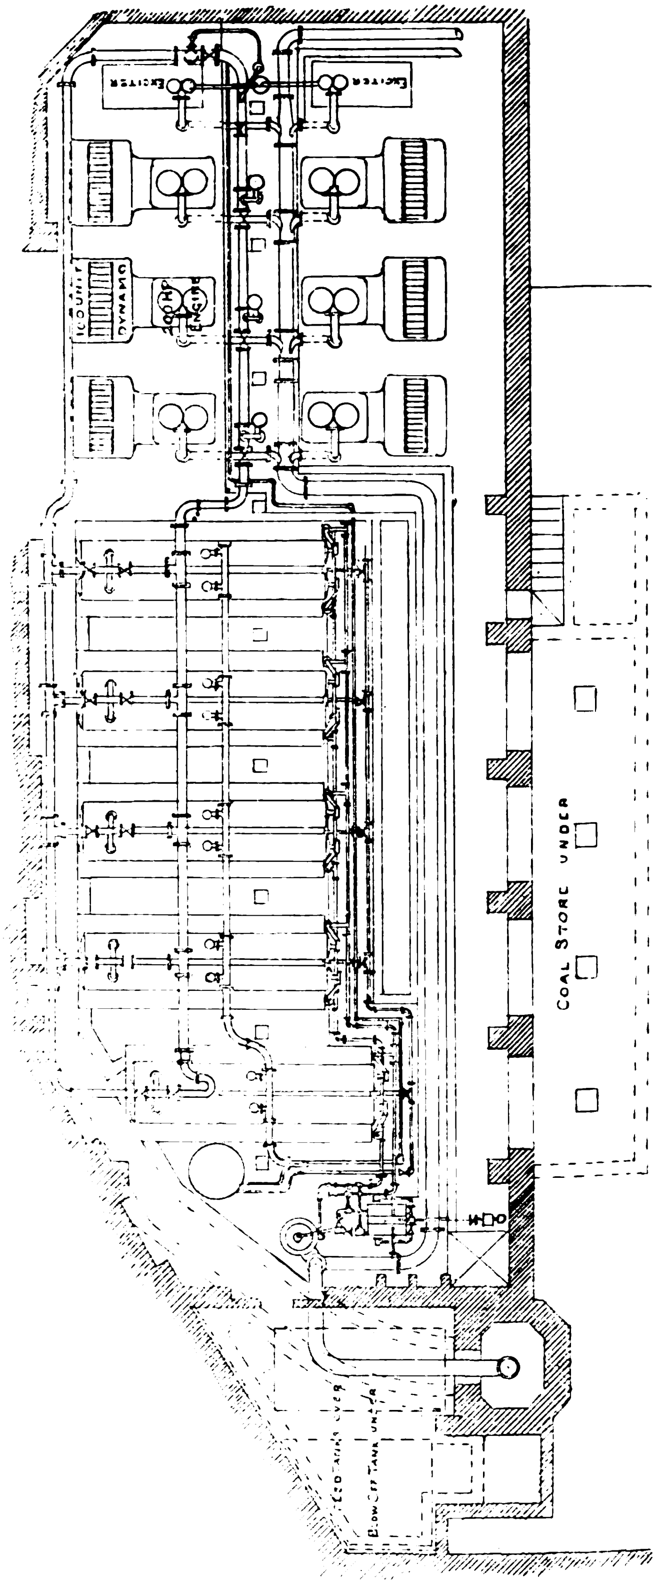

Fig. 16.—Rathbone-place Station. Plan.

group of dynamos or separately on separate groups. There are the usual rheostats for introducing resistance into the fields of the exciters. The main circuit switch-board closely resembles that of Sardinia-street which has been fully described. There are twenty-two circuits which proceed out from this board, and by means of plugs any dynamo can be put on to any circuit or group of circuits, and by means of a throw-over switch that circuit can be instantly changed on to a spare dynamo. There is one

Digitized by Google

difference, however, in the circuit switch-boards at Sardinia-street and Manchester-square, that the plugs in the circuit board in this last-mentioned station are made to screw into place for greater security instead of being simply plugged in as taper plugs. The twenty-two panels in this circuit board are all exactly similar. From this circuit board highly insulated cables pass out into a subway, where they are laid and fixed on wooden shelves. From this subway they pass into the iron pipes laid in the streets, and which have already been described in connection with the Sardinia-street station, and the arrangement of mains is otherwise the same. The difficulties which have presented themselves at Manchester-square in dealing with the limited space at disposal have been overcome with great ingenuity, and it has required the exercise of much judgment to place 2,000 horse-power in a space so limited, having regard to all the conditions of freedom from noise, vibration, and smoke. We understand that the arrangement of steam drums over the boilers, alluded to in a former part of this article (see *Electrician*, Vol. XXVI., p. 69), was designed and worked out by Mr. Rosenthal, of the Babcock and Wilcox Water Tube Boiler Company.

### Rathbone-place Station.

This station (*see* Fig. 16) is, generally speaking, designed on the lines of Manchester-square. There are six Elwell-Parker 100 unit alternators, combined with Willans engines of the same size and make as those at Manchester-square. There are two combined Willans engines and Elwell-Parker dynamos as exciters, either one of which will do the whole work of the station. There are five Babcock boilers, each capable of evaporating 6,000lb. of water per hour, and the necessary pumps, heaters, &c. Rathbone-place was formerly a small private station which was taken over by the Metropolitan Electric Supply Company in 1888 (see *Electrician*, Vol. XXIV., p. 237). The interesting point to notice about it is that whereas formerly the maximum possible output of the station was current for some 2,000 lights, by an economical utilisation of the space, and by the selection of the present plant, a possible maximum output of current for 15,000 8-candle-power lamps has been obtained. The station occupies the bottom floor of a factory, and great care has been exercised in the building construction, and by the introduction of a fire-proof roof, to render the station as free as possible from danger of interruption.

These stations of the Metropolitan Electric Supply Company are connected together by trunk mains, and in the summer, when the demand is small, it will be possible to shut down altogether one or more of these stations, and greatly to economise working expenses. At present the whole of these stations are working on the system of distributed transformers; when, however, a business has been built up, and the consumption in the areas of supply become sufficiently great, it is possible that a system of transformer sub-centres will be initiated, and be found to be advantageous.

## THE ELECTRO-MAGNET.*

BY PROFESSOR SILVANUS P. THOMPSON.

*(Continued from page 87.)*

### Electro-Magnetic Mechanism.

The task before me to-night comprises the following matters:—First, to speak of that particular variety of the electro-magnet in which the iron core, instead of being attached to the coils, is movable, and is attracted into them. Secondly, to speak of the modes of equalising the pull of electro-magnets of various sorts over their range of action. Thirdly, to describe sundry mechanisms which depend on electro-magnets. Lastly, to discuss the modes of prevention or diminution of the sparking which is so almost invariably found to accompany the break of circuit when one is using an electro-magnet.

### The Coil-and-Plunger.

First, then, let me deal with the apparatus wherein an iron core is attracted into a tubular coil or solenoid, an apparatus which, for the sake of brevity, I take the liberty of naming as the *coil-and-plunger*. Now, from quite early times, from 1822 at any rate, it was known that a coil would attract a piece of iron into it, and that this action resembled somewhat the action of a piston going into a cylinder—resembled it, I mean to say, in possessing an extended range of action. The use of such a device as the coil-and-plunger was even patented in this country in 1846, under the name of "a new electro-magnet." Electro-magnetic engines, or motors, were made on this plan by Page, and afterwards by others, and it became generally known as a distinct device. But even now, if you inquire into the literature of the text-books to know what are the peculiar properties of the coil-and-plunger arrangement, you will find that the books give you next to no information. They are content to deal with the thing in very general terms by saying: Here is a sort of sucking magnet; the core is attracted in. Some books go so far as to tell you that the pull is greatest when the core is about half-way in, a statement which is true in one particular case, but false in a great many others. Another book tells you that the pull is greatest at a point one centimetre below the centre of the coil for plungers of all different lengths—which is quite untrue. Another book tells you that a wide coil pulls less powerfully than a narrow one, a statement which is true for some cases and not for others. The books also give you

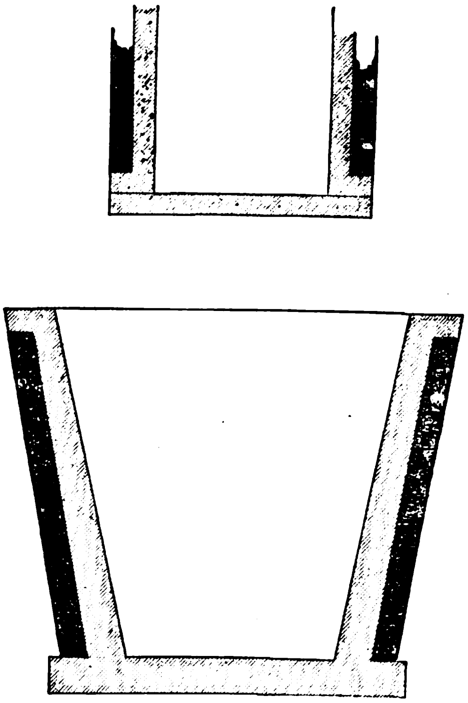

Fig. 57.—Hjörth's Electro-magnetic Mechanism.

some approximate rules, which, however, are very little to the point. The reason why this ought to receive much more careful consideration is because in this mechanism of coil-and-plunger we have a real means not only of equalising, but also of vastly extending the range of the pull of the electro-magnet. Let us take a very simple example for the sake of contrasting the range of action of the ordinary electro-magnet with the range of action of the coil-and plunger.

Here are some numbers which are given in a paper with which I have long been familiar, a Paper read by the late Mr. Robert Hunt in 1856 before the Institution of Civil Engineers, and discussed, with that eminent engineer, Robert Stephenson, in the chair. Mr. Hunt described the various types of motors, and spoke of this question of the range of action. He recounted some experiments of his own in which the following was the range of action. There was a horse-shoe electro-magnet which at distance zero—that is, when its armature was in contact—pulled with a pull of 220lb; when the distance was made only $\frac{1}{1000}$th of an inch (4 mils), the pull fell to 90; and when the distance was increased to 20 mils (1-50th of an inch), the pull fell to only 36lb. The difference from 220 to 36 was within a range of 1-50th of an inch. He contrasts this with the results given by another mechanism, not quite the simple coil-and-plunger, but a variety of electro-magnet brought out about the year 1845 by a Dane living in Liverpool named Hjörth, wherein a sort of hollow truncated cone of iron (Fig. 57), with coils wound upon it—a hollow electro-magnet, in fact—was caused

* A series of four Cantor Lectures delivered before the Society of Arts, January—February, 1890.

Digitized by Google

to act on another electro-magnet, one being caused to plunge into the other. Now we have no information what the pull was at distance zero with this curious arrangement of Hjörth's, but at a distance of 1in. the pull (with a very much larger apparatus than Hunt's) was 160lb., the pull at 3in. was 88lb., at 5in. 72lb. Here, then, we have a range of action going not over 1·50th of an inch, but over 5in., and falling not from 220 to 36, but from 160 to 72, obviously a much more equable kind of range. At the Institution of Civil Engineers on that occasion, a number of the most celebrated men, Joule, Cowper, Sir William Thomson, Mr. Justice Grove, and Prof. Tyndall, discussed these matters—discussed them up and down—from the point of view of

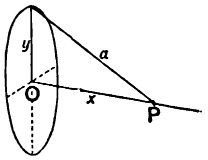

FIG. 58.—Action of Single Coil on Point-pole on Axis.

range of action, and from the point of view of the fact that there was no means of working them at that time except by the consumption of zinc in a primary battery; and they all came to the conclusion that electric motors would never pay. Robert Stephenson summed up the debate at the end in the following words:—"In closing the discussion," he remarked, "there could be no doubt from what had been said that the application of voltaic electricity, in whatever shape it might be developed, was entirely out of the question commercially speaking. Without, however, considering the subject in that point of view, the mechanical applications seemed to involve almost insuperable difficulties. The power exhibited by electro-magnetism, though very great, extended through so small a

lately whether sound varies as the square of the distance—or rather, whether the intensity of it does—and the people who dispute on both sides of the case do not seem to know what the law of inverse squares means. I have also seen the statement made last week in the columns of *The Times*, by one who is supposed to be an eminent authority on eyesight, that the intensity of the colour of a scarlet geranium varies inversely with the square of the distance from which you see it. More utter nonsense was never written. The fact is, the law of inverse squares, which is perfectly true mathematical law, is true not only for electricity but for light, for sound, and for everything else, provided it is applied to the one case to which a law of inverse squares is applicable. That law is a law expressing the way in which action at a distance falls off when the thing from which the action is proceeding is so small compared with the distance in question that it may be regarded as *a point*. The law of inverse squares is the law universal of action proceeding from a point. The music of an orchestra at 10ft. distance is not four times as loud as at 20ft. distance; for the size of an orchestra cannot be regarded as a mere point in comparison with these distances. If you can conceive of an object giving out a sound, and the object being so small, in relation to the distance at which you are away from it, that it is a point, the law of inverse squares is all right for that, not for the intensity of your hearing, but for the intensity of that to which your sensation is directed. In no case, however, are sensations absolutely proportional to their causes. When the magnetic action proceeds from something so small that it may be regarded as a point compared with the distance, then the law of inverse squares is necessarily and mathematically true.

You may remember that I produced an apparatus (Fig. 27, see *The Electrician*, Vol. XXV. p. 683), which I said was the only apparatus hitherto devised which did directly prove experimentally the law of inverse squares for the case of a magnetic pole. There was in it a pole, virtually a point at a considerable distance from a small magnetic needle, which was also virtually a point.

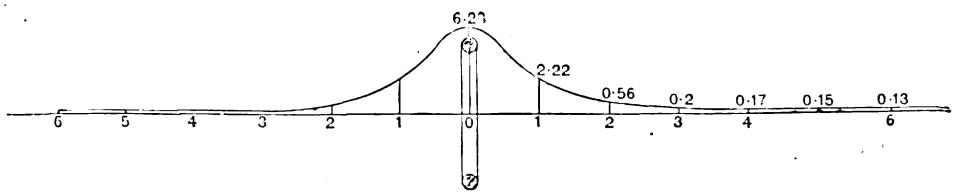

FIG. 59.—Action along Axis of Single Coil.

space as to be practically useless. *A powerful magnet might be compared, for the sake of illustration, to a steam-engine with an enormous piston, but with an exceedingly short stroke; such an arrangement was well known to be very undesirable.*"

Well, from the discussion in 1856—when this question of the length of range was so distinctly set forth—down to the present, there have been a large number of attempts to ascertain exactly how to design a long range electro-magnet, and those who have succeeded have, as a general rule, not been the theorists; rather they have been men compelled by force of circumstances to arrive at their result by some kind of—shall we call it—"designing eye," by having a sort of intuitive perception of what was wanted, and going about it in some rough and ready way of their

The law of inverse squares is true; but it is not what one works with when one deals with electro-magnets having ends of a visible size, acting on armatures themselves of visible sizes, and quite close to them. If you take a case which never occurs in practice, an armature of hard steel, permanently magnetised, so far away from an electro-magnet (or, rather, from one pole only) that the distance between the one pole and the armature on which you are acting is so very great compared with each of them, that each of them may be regarded by comparison as a point, then the law of inverse squares may be rightly applied, but not unless.

Now we want to arrive at a true law. We want to know exactly what the law of action of the coil-and-plunger is. It is not a very difficult thing to work out, provided you get hold of the right ideas.

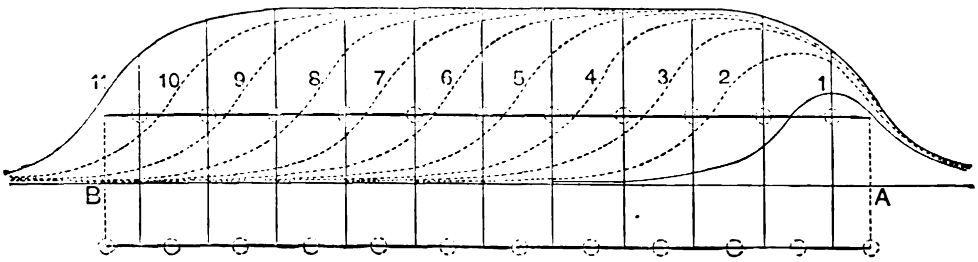

FIG. 60.—Action of Tubular Coil.

own. Indeed, I am afraid had they tried to get much light from calculations based on orthodox notions respecting the surface distribution of magnetism, and all that kind of thing, they would not have been much helped. There is our old friend, the law of inverse squares, which would of course turn up the first thing, and they would be told that it would be impossible to have a magnet that pulled equally through any range, because the pull was certain to vary inversely according to the square of the distance. I notice that, in a report of my second lecture in one of the London journals, I am announced to have said that the law of inverse squares did not apply to electric forces. I beg to remark that I have said no such thing. It is well to be precise as to what one does say. There has been a lively discussion going on quite

We must begin with a simple case, that of a short coil consisting of but one turn, acting on a single point-pole. From this we may proceed to consider the effect on a point-pole of a long tube of coil. Then we may go on to a more complex case of the tube coil acting on a very long iron core; and last of all from the very long iron core we may pass to the case of a short core.

You all know how a long tube of coil such as this will act on an iron core. Let us make an experiment with it. I turn on the current so that it circulates around the coil along the tube, and when I hold in front of the aperture of the tube this rod of soft iron, it is sucked into the coil. When I pull it out a little way it runs back, as with a spring. The current happens to be a strong one—about 25 amperes; there are about 700 turns of wire on the

Digitized by Google

coil. The rod is about 1in. in diameter and 20in. long. So great is the pull that I cannot pull it entirely out. The pull was very small when the rod was outside, but as soon as it gets in it is pulled actively, runs in, and settles down with the ends equally protruding. The tubular coil I have been using is about 14in. long; but now let us consider a shorter coil. Here is one here only half-an-inch from one end to the other, but I have one somewhere still shorter, so short that the length, parallel to the axis, is very small compared with the diameter of the aperture within. The wire on it consists of but one single turn. Taking such a coil, treating it as only one single ring, with the current going once round, in what way does it act on a magnet that is placed on the axis? First of all, take the case of a very long, permanently magnetised steel magnet, so long, indeed, that any action on the more distant pole is so feeble that it may be disregarded altogether, and only one pole, say the north pole, is near the coil. In what way will that single turn of coil act on that single pole? This is the rule, that the pull does not vary inversely as the square of the distance, nor as any power at all of the distance measured straight along the axis, but inversely as the cube of the slant distance. Let the point O in Fig. 58 represent the centre of the ring, its radius being $y$. The line O P is the axis of the ring, and the distance from O to P we will call $x$. The slant distance from P to the ring we will call $a$. Then the pull on the axis towards the centre of this coil varies inversely as the cube of $a$. That law can be plotted out in a curve for the sake of observing the variations of pull at various points along the axis. Allow me to draw your attention to Fig. 59, which represents a section or edge, view of the coil. At various distances right and left of the coil are plotted out vertically the corresponding force, the calculations being made for a current of 10 amperes, circulating once round a ring of 1 centimetre radius. The force with which such a current acts on a magnetic pole of unit strength placed at the central point is 6·28 dynes. If the pole is moved away down the axis, the pull is diminished; at a distance away equal in length to the radius it has fallen to 2·22 dynes. At a distance equal to twice the radius, or 1 diameter, it is only 0·56 dynes, less than one-tenth of what it was at the centre. At 2 diameters it has fallen to 0·17 dyne, or less than 3 per cent.; and the force at 3 diameters is only about 2 per cent. of that at the centre.

If, then, we could take a *very* long magnet, we may utterly neglect the action on the distant pole. If I had a long steel magnet with the south pole 5ft. or 6ft. away, and the north pole at a point 3 diameters (*i.e.*, 6 centimetres in this case) distant from the mouth of the coil, then the pull of the current in one spiral on the north pole 3 diameters away would be practically negligible; it would be less than 2 per cent. of what the pull would be of that single coil when the pole was pushed right up into it. But now, in the case of the tubular coil, consisting of at least a whole layer of turns of wire, the action of all of the turns has to be considered. If the nearest of the turns of wire is at a distance equal to three diameters, all the other turns of wire will be at greater distances, and, therefore, if we may neglect such small quantities as 2 per cent. of the whole amount, we may neglect their action also, for it will be still smaller in amount. Now, for the purpose of arriving at the action of a whole tube of coil, I will adopt a method of plotting devised by Mr. Sayers. Suppose we had a whole tube coiled with copper wire from end to end, its action would be practically the same as though the copper wire were gathered together in small numbers at distant intervals. If, for example, I count the number of turns in a centimetre length of the actual tubular coil which I used in my first experiment, I find there are four. Now if, instead of having four wires distributed over the centimetre, I had one stout wire in the middle of that space to carry four times the current, the general effect would be the same. This diagram (Fig. 60) is calculated out on the supposition that the effect will not be greatly different if the wires were aggregated in that way, and it is easier to calculate. If, beginning at the end of the tube marked A, we take the wires over the first centimetre of length and aggregate them, we can draw a curve, marked 1, for the effect of that lot of wires. For the next lot we could draw a similar curve, but instead of drawing it on the horizontal line we will add the several heights of the second curve on to those of the first, and that gives the curve marked 2; for the third part, add the ordinates of another similar curve, and so gradually build up a final curve for the total action of this tubular coil on a unit pole at different points along the axis. This resultant curve begins about 2½ diameters away from the end, rises gently, and then suddenly, and then turns over and becomes nearly flat with a long level back. It does not rise any more after a point about 2½ diameters along from A; the curve at that point becomes practically flat, or does not vary more than about 1 per cent., however long the tube may be. For example, in a tubular coil 1in. in diameter and 20in. long, there will be a uniform magnetic field for about 15in. along the middle of the coil. In a tubular coil 3 centimetres in diameter and 40 centimetres long, there will be a uniform magnetic field for about 32 centimetres along the middle of the coil. The meaning of this is that the value of the magnetic forces down the axis of that coil begins outside the mouth of the tube, increases, rises to a certain maximum amount a little within the mouth of the tube, and after that is perfectly constant nearly all the way along the tube, and then falls off symmetrically as you get to the other end. The ordinates drawn to the curve represent the forces at corresponding points along the axis of the tube, and may be taken to represent not simply the magnetising force, but the pull on a magnetic pole at the end of an indefinitely long, thin steel magnet of fixed strength.

*(To be continued.)*

## REVIEWS.

**Electric Bell Construction.** F. C. Allsop. E. and F. N. Spon: London, 1890.

This book will give an amateur a fair idea of the construction of electric bells, indicators, and magnetos; but it contains no information about wholesale manufacture, nor does it touch upon wiring, which is dealt with in another book by the same author. "Is electricity within the grasp of the ironmonger? I say most distinctly it is," writes a correspondent to *Ironmongery*; but we cannot with equal confidence assert that Ohm's law is within the grasp of our author. He gives a diagram of a Leclanché cell coupled up with a push and a bell. On the previous page he has given the volts of this as 1½ roughly. He then supposes the resistance of the circuit to be 1½ ohms, and arrives at the conclusion that "the current in the circuit will be exactly one ampere." "In Fig. 4, however, we have added another cell, which has doubled the E.M.F., so that, the resistance being the same, the current is also doubled, being two amperes instead of one." It is a very common mistake among beginners to neglect the resistance of a battery, especially when no information as to the resistances of various batteries is given in the text-books; but we hoped for better things from the author of four books on electrical matters.

**Electromotors.** How made and How Used. By S. R. Bottone. Whittaker and Co.: London, 1890.

This is essentially an amateur's book. But there are amateurs and amateurs. Some turn geometric patterns on ivory boxes, some play at manufacturing, and others, alas! follow the suggestions that we find in this little book, and mount toy armatures on knitting-needle shafts with a copious use of Prout's glue. The author, after describing these electrical whirligigs, proceeds to give instructions for making small motors, and a persevering amateur might succeed in turning out something that would go, if he follows the directions; but many details, such as the rounding of the corners of an armature over which wire has to be wound, are omitted, while the directions for winding are needlessly prolix. A good deal of space is taken up with descriptions of Immisch and other really serviceable motors, while the last fourth of the book is devoted to alternate current motors which can hardly be of use to an amateur at present. The method of calculating the winding of armatures and of fields is very remarkable. The unfortunate amateur might as well be told to guess at the half, and to multiply by the cube root of 8. Allusion is made to the statement that "it will be seen on reference to a 'properties of copper wire table' that the 'safe current' for No. 18 wire is only three amperes, while that of No. 16 is six amperes." Surely the author must know that arc light dynamos have been made for years with No. 18 wire for nine amperes, and No. 17 has often been used for 15 amperes. A two-page table is given of primary batteries, their chemicals and volts, and a praiseworthy attempt is made to give their internal resistances.

## THE PHYSICAL SOCIETY.

The following communication was made at the meeting of the Physical Society on November 14th by the Rev. T. PELHAM DALE, M.A.,

### "On certain relations existing amongst the refractive indices of the Chemical Elements."

The first part of this Paper corroborated the results announced in a communication made in May, 1889, on the same subject, and said that as far as experimental data are forthcoming, the refraction $(\mu - 1)$, divided by the vapour density $(d)$ is equalled to a constant multiplied by some integer. Several metals whose refractions have since been determined conform to this law. On examining the relation between molecular weight (M) and refraction, similar conclusions are arrived at, for to a fair degree of approximation the ratio $M/\mu - 1$ is a constant or simple multiple of this constant. Another relation is between the molecular distances $(h)$ (see *Proc. Phys. Soc.*, Vol. IX., p. 167) and the atomic weight $(a)$ of the elements, $h$ being nearly proportional to $\sqrt{a}$. In the case of selenium, sulphur, and phosphorous the agreement is close, but for bromine, chlorine, and carbon not so good. A relation appears to exist between the upper limit of refraction and the line spectra of elements. For example, the upper limit of refraction for selenium occurs at wave length 5295 7, whilst its spectrum exhibits a remarkable series of strong lines about this wave length. A similar relation apparently holds with sulphur, phosphorous, and bromine. Gold also shows a series of strong lines about C, in the vicinity of which the metal has the greatest reflective power.

DISCUSSION.

Dr. GLADSTONE said that the question whether $(\mu - 1)/d$ is constant or not, is being investigated by many. The French physicists had found the quantity nearly constant, but Lorenz's expression, $(p^2 - 1)/(p^2 + 2)$, is slightly better when applied to compounds in the liquid and gaseous states. Metals were difficult to deal with, especially as, according to the recent Paper of Du Bois and Reubens, their refractions do not follow the law of sines.

Mr. DALE here suggested that they might be related to hyperbolic sines.

Dr. GLADSTONE, continuing, said that by taking solutions of metals, it was found that their specific refractive energies were nearly inversely as the square roots of their combining weights, but at present the known cases were not sufficient to establish a law.

Prof. RÜCKER said that of the two expressions, $(\mu - 1)/d$ and $\frac{(\mu^2 - 1)}{(\mu^2 + 2)}$ the latter seemed preferable, for it could be converted into electrical quantities by writing $\kappa$ for $\mu^2$. The expression then becomes $(\kappa - 1)/(\kappa + 2)$, and if this can be shown to be constant by electrical work, this would be an argument in its favour.

Mr. DALE, in reply, pointed out that from the nature of the two formulæ, any inaccuracy or variation in $\mu$ would affect theirs more than Lorenz's. He also thought that $(\mu - 1)/d$ was a limit towards which the numbers tend.

Prof. J. PERRY, F.R.S., then read a Paper

### "On Tables of Spherical Harmonics, with Examples of their Practical Use."

The author, for the benefit of members of the Society not familiar with the subject, defined a spherical harmonic as a homogeneous function of $x$, $y$, $z$, satisfying the equation $\frac{d^2 V}{d x^2} + \frac{d^2 V}{d y^2} + \frac{d^2 V}{d z^2} = 0$, stated some of the fundamental properties of these functions, and pointed out their importance in the solution of various problems in heat, electricity, and general dynamics. It will be observed that the defining equation is the well-known one, satisfied when V is the potential of an attracting mass of matter, at all points unoccupied by matter. If V is the potential of an electrostatic distribution, it is satisfied at all points of no electrification. Lastly, if V is a magnetic potential, the equation is satisfied at all points within a homogeneous substance in a magnetic field, and at all points of empty space. The general spherical harmonic of any degree, being a function of the three co-ordinates $x$, $y$, $z$, is called a solid harmonic. By transforming to polar co-ordinates $r$, $\phi$, $\theta$, it can be shown that from a solid harmonic of degree $i$, a function of $\phi$ and $\theta$ only which also satisfies the equation, can be derived by dividing by $p^{2i+1}$, and this is called a surface harmonic. Spherical harmonics which are independent of $\phi$ are known as zonal harmonics, and are of special importance, as being applicable to the solutions of all problems in which there is symmetry about an avis. The surface harmonics of this class are functions of $\theta$ only, and the solid harmonics derived from them are, of course, functions of $r$ and $\theta$, or of $x^2 + y^2$ and $z$.

It was the surface zonal harmonics or functions of a single angle only which Prof. Perry had tabulated, the tables giving the values to four places of decimals of the functions of degrees 0 to 8 for every degree of arc from 0° to 90°.

As an example of the use of these tables, the case of a spherical surface covered with attracting matter whose density varied as the square of its distance from a diametral plane, was taken. It was required to find the potential both outside and inside the sphere, and to determine the equipotential surfaces and lines of force. The potentials inside (A) and outside (B) were shown to be given by

$$\frac{A}{\pi} = 8 + \frac{16}{5} r^2 P_2, \text{ and } \frac{B}{\pi} = \frac{8}{r} + \frac{16}{5} \frac{1}{r^3} P_2 \text{ respectively.}$$

By giving A and B definite values, and choosing values of $r$, the corresponding $P_2$'s can be calculated and the value of $\theta$ determined from the tables. Hence any equipotential surface can be easily determined; and lines drawn to cut these surfaces orthogonally are the lines of force. Another problem which had been tried, consisted in finding the directions of the lines of force near a circular coil of rectangular cross-section when an electric current circulates in the coil. This was treated approximately by first calculating the potential at 6 points along the axis in the neighbourhood of the coil, and then finding by Gauss' method the coefficient $A_0$, $A_1$, $A_2$, &c., of an expression in ascending powers of $z$ which agreed with the calculated potentials at the points chosen. The formula, $V = A_0 + A_1 r P_1 + A_2 r^2 P_2 t$, &c., or its corresponding expressions in inverse powers of $r$ was then assumed to give the potential at any point in the space considered. By giving V definite values a series of equipotential surfaces were determined, and the lines of force drawn. On putting the calculations to the test of experiment, the approximate solution of this very difficult problem was found to be very nearly correct.

DISCUSSION.

Prof. A. W. RÜCKER observed that these tables would be of the utmost value to all physicist who require to make calculations involving spherical harmonics. He himself, in the course of his magnetic work, had reluctantly abandoned some calculations of the kind owing to the enormous labour which would have been involved in calculating the numerical values of the functions. The calculations would have been made with ease if he had had access to tables such as those which Prof. Perry had presented to the Society.

Mr. G. W. DE TUNZELMANN thought that the publication of these tables, which could be consulted as easily as the ordinary tables of trigonometrical functions, ought to do much to dispel the mystery which had hitherto been associated with the term spherical harmonic in the minds of practical engineers.

Prof. J. V. JONES stated that it was of great interest to him as a teacher to learn that Prof. Perry had been able to introduce the subject successfully to elementary classes.

## THE BOARD OF TRADE OVERHEAD WIRE REGULATIONS.

The following two memorials, which have recently been forwarded to the Board of Trade upon the subject of the regulations relating to overhead conductors, may prove of interest to our readers :—

London, November 6, 1890.

To the Right Hon. Sir MICHAEL EDWARD HICKS-BEACH, Bart., M.P., President of the Board of Trade.

SIR: We, the undersigned companies, firms, and persons, interested in the supply of electricity in the United Kingdom, beg respectfully to memorialise your Board with reference to Regulation No. 9 of the regulations for the protection of the public safety, &c., prescribed by the Board of Trade under the provisions of the Electric Lighting Act of 1882.

With reference to this regulation the undersigned beg leave to state that it is the general experience based upon numerous actual tests, that for pressure up to 2,000 volts, whether alternating or continuous current, a thickness of one-tenth of an inch of dielectric is unnecessary in conductors of small section. For conductors having a relatively large sectional area we are satisfied with the expediency of the Board of Trade requirements; but for conductors having a relatively small sectional area, the disproportion between the conductor and the installation is so excessive as not only to render the use of such conductors prohibitory, in view of their high price, but actually dangerous in the presence of snow and high winds, on account of the very large surface presented in proportion to the total weight of the conductor and its covering.

Four of the principal companies interested in this branch of work, viz., The Brush Electrical Engineering Company (Limited), Messrs. Crompton and Company (Limited), The India rubber and Gutta-percha Company (Limited), and Messrs. Laing, Wharton, and Down Construction Syndicate (Limited), were represented at the experiments carried out at the works of Messrs. Crompton and Company, at Chelmsford, by your adviser, Major Cardew, and their representatives were so thoroughly convinced by these experiments of the reasonable character of their request for a modification of the exist-

Digitized by Google

ing rule, that the above-mentioned Companies heard of the receipt by Messrs. Crompton and Co. of the letter from the Board of Trade, dated May 30th, with the greatest astonishment and regret.

The undersigned beg leave, therefore, most respectfully to request the Board of Trade to give the decision therein communicated their favourable reconsideration, and to suggest that this rule may be modified in accordance with the following :—"Every high-pressure aerial conductor must be continuously insulated with a durable and efficient material, to be approved of by the Board of Trade, and to a thickness of not less than one-seventh part of the actual conductor diameter in cases where the extreme difference of potential does not exceed 2,000 volts ; but for all higher voltages this thickness must be increased in direct proportion to the increase in difference of potential. In no case must the thickness of insulation be less than one-sixteenth of an inch, and the cables must have an insulation resistance of not less than one megohm per mile per volt of electromotive force when tested in water at 60°Fahr. (after immersion of at least 60 consecutive hours). This insulation must be further efficiently protected on the outside against injury or removal by abrasion. If this insulation or protection be wholly or partly metallic, it must be efficiently connected to earth, so, however, as not to cause undue disturbance to other electric lines or works by electrostatic induction or otherwise."

The undersigned are willing and anxious to conduct any additional tests which the Board of Trade may wish or suggest, in proof of the contentions herein stated. The undersigned make these representations while fully recognising the necessity in the interests, not only of the public, but also of the electrical industry generally, that all overhead electric lines should be carried out in the safest possible manner.—We have the honour to be, Sir, your most obedient servants,

(Signed) THE BRUSH ELECTRICAL ENGINEERING COMPANY (LIMITED).
MESSRS. CROMPTON AND CO. (LIMITED).
THE INDIA-RUBBER AND GUTTA-PERCHA COMPANY (LIMITED).
THE LAING, WHARTON, AND DOWN CONSTRUCTION SYNDICATE (LIMITED).

London, November 6, 1890.

To the Right Hon. Sir MICHAEL EDWARD HICKS-BEACH, Bart., M.P., President of the Board of Trade.

SIR: We, the undersigned companies, firms, and persons, interested in the supply of electricity in the United Kingdom, beg respectfully to memorialise your Board with reference to Regulations Nos. 2 and 12 of regulations for the protection of the public safety, &c., prescribed by the Board of Trade under the provisions of the Electric Lighting Act of 1882.

With reference to these regulations the undersigned beg leave to bring before the Board the fact that in conjunction with overhead conductors having a small sectional area of copper, the use of suspending wires is not only unnecessary but exceedingly dangerous to public safety, on account of the large surface presented to wind and snow, and the great strain put upon the supports. It is admitted that this does not apply with so much force to the use of suspending wires with conductors of relatively large sectional area, but the undersigned are strongly of opinion that both in the interests of the electrical industry, and in those of public safety, it is advisable that overhead conductors up to a sectional area of hard drawn copper, equivalent to 7 No. 16 S.W.G. should be run without suspending wires. The undersigned beg leave, therefore, most respectfully to request the Board of Trade to give their favourable reconsideration to the foregoing regulations, and to suggest that they may be modified in accordance with the following :—

*Clause* 2.—"Every aerial conductor shall be attached to supports at intervals not exceeding 200ft. where the direction of the conductor is straight, or 150ft. where this direction is curved, or where the conductor makes a horizontal angle at the point of support. If suspending wires are used, as required in Clause 12, the above intervals may be increased to 250ft. and 200ft. respectively.

*Clause* 12.—Every aerial high pressure conductor shall be efficiently suspended by means of non-metallic ligaments to suspending wires, so that the weight of the conductor does not produce in it any sensible stress in the direction of its length, and the insulated conductors and suspending wires where attached to supports shall be in contact only with material of highly insulating quality, and shall be so attached and guarded that in case they break away it shall not be possible for them to fall away clear of the supports. Provided that where the aerial high-pressure conductor is equal to, or less than, 7 No. 16 S.W.G., the suspending wires shall not be compulsory if the conductor be of hard drawn copper or other material of equal strength.

The undersigned are willing and anxious to conduct any tests which the Board of Trade may wish or suggest in proof of the contentions herein stated. The undersigned make these representations while fully recognising the necessity in the interests, not only of the public, but also of the electrical industry generally, that all overhead electric lines should be carried out in the safest possible manner.—We have the honour to be, Sir, your obedient servants,

(Signed) THE BRUSH ELECTRICAL ENGINEERING COMPANY (LIMITED).
MESSRS. CROMPTON AND CO. (LIMITED).
THE LAING, WHARTON, AND DOWN CONSTRUCTION SYNDICATE (LIMITED).

## OVERHEAD ELECTRIC LIGHT CONDUCTORS.

The following illustrations (Figs. 1 and 2) represent three varieties of aerial conductors. No. 1 is that required by the Board of Trade. No. 2 is a compromise which has been suggested by Mr. Crompton. No. 3 is an ordinary conductor such as has been in vogue up to the present for the class of work for which the Board of Trade now demands No. 1.

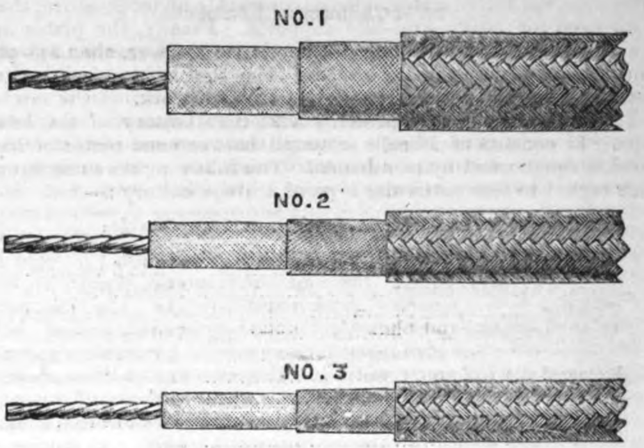

FIG. 1.—Cables with covering partly cut away.

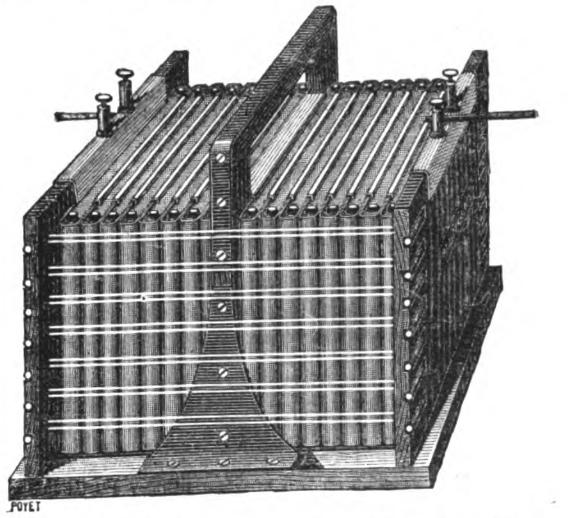
FIG. 2.—Cross section of cables.

No. 1. $\frac{7}{20}$ cable. Insulated according to Board of Trade regulations. Thickness of rubber, ·121" Diameter over serving, ·489".
No. 2. $\frac{7}{20}$ cable. Medium insulation. Thickness of rubber, ·07". Diameter over serving, ·355".
No. 3. $\frac{7}{20}$ cable. L quality. Thickness of rubber, ·042". Diameter over serving, ·306.

## THE REYNIER ELASTIC ACCUMULATOR.

On p. 186 of our issue of June 20, 1890, our Paris correspondent supplied a few general facts respecting a new accumulator brought out by M. Emile Reynier, and the following additional data have now been sent us by the inventor :—



Reynier's Elastic Accumulator.—Type : Horse-Power-Hour.

In the original design each cell was contained in a varnished sheet-iron vessel lined with india-rubber, and was composed of two positives and one negative, separated by sheets of porous silica, the two end sheets being fluted to increase the space available for the electrolyte, the quantity of which was, however, small. In the latest type of cell M. Reynier uses containing vessels of pure lead, the necessary flexibility being obtained by surrounding the lead

Digitized by Google

**cell with an expansible corrugated case. A number of cells are connected in series, and placed between two rigid end-pieces drawn tightly together by strong springs. This arrangement gives the active material considerable artificial elasticity, which enables one to attain a high rate of discharge and to obtain a high output for a given weight. The expansions and contractions of the plates can take place freely without disintegration owing to the action of the springs. There is a difference in length of as much as 6 per cent. between a completely discharged and a fully charged battery. Moreover, the active material being constantly under pressure, there is no need for heavy grid-like supports. Finally, the plates and the cells being held together in this elastic manner, they are able to withstand severe shocks, and are from that point of view alone peculiarly suited to the exigencies of traction work.**

**The annexed figure represents a storage battery of the latest type. It consists of 16 cells mounted between end-pieces of hard wood, strengthened by iron bands. The following are some figures with regard to this particular type of storage battery :—**

| | | |
|---|---|---|
| E.M.F (full) | | 32 volts |
| E.M.F. (at terminals) | | 28 ,, |
| Discharging current | | 3 to 6 amperes. |
| Average available energy | | 150 watts. |
| Capacity | | 30 ampere-hours. |
| Work (available) | | 740 watt-hours. |
| External dimensions | Length | 16 |
| | Breadth | 12″ |
| | Height | 12″ |
| Total space occupied (less than) | | 1·5 cubic feet. |
| Total weight | | 110lb. |
| Weight per watt-hour | | ·15lb. |
| Watt-hours per lb. of cell complete | | 6·73 |
| Volume per watt-hour | | 3 cubic inch. |

**It may be added that the figures for the total weight and total volume include everything, and that the battery is very solidly constructed in view of its employment in electric tramway and similar work.**

## DINNER OF THE INSTITUTION OF ELECTRICAL ENGINEERS.

The second annual dinner of the Institution of Electrical Engineers was held on Thursday evening, November 20th, at the Criterion Restaurant, under the presidency of Dr. John Hopkinson, F.R.S. Amongst those present were the Postmaster-General, the Attorney-General, the President of the Royal Society, the Astronomer Royal, Dr. Coleman Sellers, Sir Arthur Blackwood, K.C.B.; Sir H. Trueman Wood, Major Marindin, R.E.; Sir Robert Rawlinson, K.C.B.; Mr. George Berkeley, Mr. J. Tomlinson, jun., Captain Wharton, R.N.; Prof. W. G. Adams, Mr. Alabaster, Prof. Ayrton, Mr. Aylmer, Dr. Borns, Mr. Bidwell, Sir Albert Cappel, Major Cardew, R.E ; Mr. Collett, Staff-Commander Creak, Mr. Crompton, Mr. Crookes, Mr. Dowson, Sir James Douglas, Mr. Eck, Dr. Fleming, Prof. Foster, Prof. Forbes, Herr Fritsche, Sir Douglas Galton, Mr. Graves, Mr. R. Kaye Gray, Mr. W. E. Gray, Mr. C. H. Gray, Capt. Holden, R.A.; Dr. E. Hopkinson, Prof. Hughes, Colonel Jackson, Sir Henry Mance, Mr. Mordey, Prof. Perry, Mr. Preece, Mr. von der Pfordten, Sir David Salomons, Mr. Alex. Siemens, Mr. Spagnoletti, Major-General C. B. Stotherd, R.E. ; Mr. Stroh, Mr. W. Swan, Prof, S. P. Thompson, Prof. J. J. Thomson, Prof. W. C. Unwin, Major-General Webber.

The PRESIDENT, in giving the toast of "Her Most Gracious Majesty the Queen," said that it was one peculiarly acceptable to electrical engineers, for during Her Majesty's reign the science of electrical engineering had not only attained to its present development, but had found its beginning.

The PRESIDENT, in giving "The Prince and Princess of Wales and the rest of the Royal Family," said they all knew how willingly and ably the Prince of Wales represented Her Majesty on all ceremonial occasions. The other day he was present at the opening of the Forth Bridge ; and again lately he had been at the opening of the City and South London Railway, a work which had been peculiarly interesting to electrical engineers from the mode of its propulsion.

The PRESIDENT next gave "The Army, the Navy, and the Reserve Forces," coupled with the names of Major-General Stotherd, C.B., R.E., and Captain W. J. L. Wharton, R.N.

Major-General STOTHERD, in reply, said that it was necessary to spend a great deal upon the Army and the Navy of late years to keep them in a state of efficiency. Amongst the things which cost money were the scientific inventions which had been introduced into the Army within his recollection. When he was at Chatham, some years ago, he had the pleasure of initiating the field telegraph system of our Army and the system of submarine mines which had since been adopted. When first formed, many of the members of the Institution offered very useful information and assistance in developing our system of military telegraphs and torpedoes and submarine mines. He could not refrain from mentioning the name of Sir William Siemens, who in particular had taken very great interest in developing the apparatus when submarine mines were first adopted. Sir Francis Bolton, also a member of the Institution, organised a very excellent system of visual telegraphy. This country was the first to use the electric telegraph for warlike purposes. In the Crimea they carried a line from Balaclava to the front. After that, in 1866, the electric telegraph was very extensively used in the German army.

Captain WHARTON, R.N., returned thanks for the "Navy," and referred to the vast changes that had taken place in the *matériel* of the fleet in the past 30 years, and the criticism and controversy that was naturally called forth by the experimental condition of ships and guns, but deprecated illogical strictures such as had recently been current on the "Serpent," which was a perfectly seaworthy ship, though of a class not liked by seamen for their discomfort. He hoped that evidence would be forthcoming at the court martial to clear the memory of officers of that ship from any imputation of careless navigation.

The PRESIDENT then proposed "Her Majesty's Ministers." He said, whether they agreed or not in the judgment of Her Majesty's Ministers in matters of policy, they would all agree in according to them credit for a very honest desire for the good of the country. He could not ask them all to wish long life to the Ministry ; but he did ask them all to join him in wishing health and long life to every member of that Ministry. He coupled with the toast the name of Mr. Raikes, Her Majesty's Postmaster-General. A very important part of the work of his department was entirely dependent upon the electrical engineer.

The Right Hon. H. C. RAIKES, M.P., in returning thanks, said :—Mr. President, it is I am aware, no small honour to return thanks for the toast of Her Majesty's Ministers in such a company and on such an occasion as this. And yet I feel some little diffidence in addressing myself to the task when I remember that it has been previously performed by no less a personage than the head of the present Government, the Marquis of Salisbury (cheers). He was your guest last year ; and he is not only the head of Her Majesty's Government, but he is what I cannot pretend to be, a somewhat expert electrician himself. I have near me another friend of mine who also belongs to Her Majesty's Government, the Attorney-General, who is also, I daresay, known to many gentlemen here, not less as an electrical expert than as a profound lawyer, if he will forgive me for saying so. I remember upon one very important occasion I had recourse to his advice, when I found, in my humble opinion, that his electricity was at least as good as his law. At all events, his electrical skill enabled us so to steer out of a difficulty in which otherwise we might have had to fall back upon his law. I feel that you have done me this honour, perhaps, to-night, for the cause indicated by your President in his speech. It is, no doubt, the fact that the department which I am called upon to preside over has closer relations with electrical engineering than any other great department of the State. It is not necessary that I should refer in detail to the enormous amount of telegraphic business which has grown up during the nineteen years through which the department of the Post Office has been charged with its administration in this country ; but it is perhaps interesting to know that in that time the annual number of telegrams has grown from 10,000,000 in 1871 to 62,000,000 in 1889, that it has more than sextupled in the course of those eighteen years, and you can easily understand how important it is for our department to be kept *au courant* with all the latest developments of electrical science. It is not without some feeling of pride that I recall the fact that the Post Office has, I believe, given to this institution no less than three of its presidents—Mr. Scudamore, Mr. Preece, and Mr. Graves. They, I believe, each in turn occupied that chair which you, sir, fill to-night, and I am happy to think that they have been able to render great services to the science of electricity, at the same time that they have not been thereby induced in the smallest degree to neglect their public duty to the department which they so efficiently serve. But it is not the Post Office alone that has relations with electrical engineering. Second only to the Post Office—if indeed second—is the Board of Trade in its relations to your science. The Board of Trade has, amongst other things, the special charge of lighthouses ; and the Board of Trade has had the opportunity of testing, and I believe of utilising, more than one of the considerable discoveries of your President in that branch of electrical science. We can only regret that in the neighbouring country of Spain, on whose shores that terrible catastrophe happened the other day, there is not, as far as I am aware, either a Board of Trade or an Institution of Electrical Engineers. If they had the advantages we possess we might hope and believe that the lights at Cape Villano might have been in such a state as to have prevented the loss of that good ship and all those brave men. Now, the Board of Trade is not only interested in the question of lighthouses, but it also has to do with the great question of electric lighting. I know that many gentlemen, and I dare say the majority of those here present, have the opinion that electric lighting has been perhaps unduly arrested in this country by the jealousy of Parliament or of the departments of the Government (hear, hear). Well, I can quite understand that feeling, but I confess that I do not share it. I think that above all things when you have a young science it is desirable that you should give that science time to feel its feet, and to, in some degree, appreciate what it can do before you rush headlong into employing it. I cannot but think that Parliament has been wise in holding its hand for some years before taking decided steps for licensing and extending the use of the electric light, because no doubt it has given time for experiments greatly to improve the science and to secure for the public, now that they are beginning to appreciate and make use of it, a very much better article in the way of electric light than they would have obtained probably if they had rushed into it eight or ten years ago. Then the Board of Trade has

Digitized by Google

another connection with the electrical engineers with respect to electricity as a motive force. The recent opening of the new subterranean railway in South London has given us all an opportunity of testing, by actual experience, how this most interesting experiment will work, and it will be the special duty of the Board of Trade to keep its eyes open to study the working of the new system and to report upon it in an independent way, which will enable the public generally to judge for themselves how far that experiment may be imitated elsewhere. Then the Admiralty has its relations with electrical engineering, because from day to day it is becoming more and more necessary to have recourse to electricity in handling those great monsters of the deep, which are the fighting ships of our day, and which are so ponderous and so unwieldy that ordinary skill might be powerless to handle them. The War Office, as you know, has its own dependence also on electrical engineering, for no man nowadays could take the field for a campaign unless he had obtained the very best service that was to be obtained for the supply of information. Therefore, you see that all those departments of State are separately very much beholden to the Electrical Engineers. I may tell you, on behalf of them all, as I address you this evening, that I tender to you the grateful thanks of Her Majesty's Ministers for the great services which you have rendered to them. I know that it is almost impossible, in dealing with the operations of a body like yours, to over-estimate the enormous changes which, through your instrumentality, are affecting our daily life. I am not going to say, as I believe some enthusiasts say, that you have actually annihilated time and space ; but you have so far modified time and space that it is impossible for those who live in this our day to attach to those words anything like the sense in which they were used, even by the preceding generation. And you are perpetually finding out new fields. It is not merely that you have covered all those various grounds to which I have already referred, but you are making for yourselves a great field in manufactures ; and even in the healing art electricity is coming to play a very important part. It is impossible to forecast the enormous future that lies before this particular branch of science. You seem to me to have taken to yourselves the attributes of the whole of the Pantheon, the whole of those influences which in ancient times were supposed to dominate our sublunary life. But if I had to single out among those mythological deities any one which might seem more appropriately to be the patron or patroness of your science, I would say that you seem to me to have borrowed in a special degree the attributes of that goddess who we remember—probably those of us who still retain the rudimentary features of our school training—adopted a threefold name and a threefold aspect. If you will forgive me I will merely quote those two lines with which our Latin grammar has made us familiar –

"Terret, lustrat, agit Proserpina, Luna, Diana,
Ima, suprema, feras, sceptro, fulgore, sagittâ."

As I was coming down here I thought perhaps I might venture to string together this little paraphrase of those lines, which I would render thus :—

"Your threefold goddess, with her magic spells,
By turns alarms, enlightens, and impels,
While hangs the pale exchange upon her strings,
Her lamp cheers cities and her touch gives wings."

(Applause.)

Mr. LATIMER CLARK next proposed "The Learned Societies." He said it was absolutely unnecessary in a meeting such as that to give any commendation or recommendation to that toast. They all knew perfectly well what the learned societies had done for their own and other branches of science. They knew that they had given lustre to the times in which they lived. They had to a large extent perhaps done benefits to them greater than to any body of men he could recall. The learned societies of this country and of other countries had been enabled to pursue not only the love of science and the desire to gain knowledge, but also they had been enabled to attain, or to endeavour to attain, absolute truth ; and, as far as he could see, no other human agency was able to seek after truth with such a pure ambition and motive as the "Learned Societies." Whatever might be the consequences to themselves or to others, they sought truth, absolute truth, and truth only.

Sir GEORGE STOKES, Bart., M.P., in responding for "The Learned Societies," said it was a very wide subject indeed if they took in all the societies which deserved that name. But from the nature of this institution, and from the speech of the gentleman who had proposed the toast, he supposed they did not mean on the present occasion to include under that term literary and philological societies, but to confine themselves more especially to scientific societies. But here again the field was somewhat limited, because he perceived that there was another toast which would be proposed in due time, which would be "The Kindred Societies"—societies kindred to the Electrical Engineers. Now, he certainly should himself regard the Institution of Electrical Engineers as a scientific society, and therefore he was still further limiting the term scientific society in relation to this toast. It was quite true that there were societies whose object was the abstract discovery of scientific truth, apart from its applications, and no doubt that those discoveries formed the groundwork of subsequent applications. There were many societies devoted to particular branches of science with which electrical engineering was brought more especially into contact. It was brought into contact even with abstract mathematics. It was brought into contact, again, with chemistry, for the strange agent that they had to deal with, and turned so much now to practical account, electricity, was intimately, as they knew, bound up with chemistry. It was not the first time that he had responded to such a toast as that ; it was not the first time that he had responded to that very toast at the hospitable board of that very society. There was a certain circumstance which led him to look more, perhaps, to the future than to the past. No doubt his name had been connected with this toast in consequence of the honourable office which for the present he was filling, but his tenure of that office was now drawing to a close. In a few days he should cease to hold it. Who his successor might be he ought not to say, because that was determined by the votes of the Fellows, and those votes were given by ballot. Yet he thought it was what he might call an open secret that in all human probability his successor would be one who was somewhat his junior in age, but whom he might look up to as his master in science, and more especially in electrical science. His probable successor—he supposed he ought not to say more than that—would be one who was well acquainted with them, and who had already filled the post which his friend on the right occupied at that very moment. He rejoiced to think that his probable successor would be a gentleman such as he had described, and one who was connected with that institution.

Mr. W. H. PREECE, past President, next proposed "The Kindred Societies." He said the toast that had been placed in his hands was that of the kindred societies ; and after the remarks that had just been made by the President of the Royal Society, he had considerable difficulty in defining to them who those "Kindred Societies" were, and in arranging those societies in some system of method and of order. He took them thus : that the kindred societies were those who, like themselves, were occupied in the application of the great principles that were discovered by the learned societies. Now, in attempting to arrange those kindred societies in any order, he had no library to refer to. He had simply before him the *menu* of the capital dinner which they had enjoyed, and he took it that they could speak lightly, perhaps foolishly, of some of those societies under the different heads that they had taken their food. For instance, "soup." What society was it that could be arranged under the head of "soup?" They heard sometimes of papers that were "thick," papers that were "thin ;" they had subjects that were "hot," and subjects that were "cold." They had occasionally papers brought before them that were "spiced ;" but there was one society where they also had papers that formed the subject of admirable discussions, that were weekly submitted to them with a promptitude that was astonishing, and those were the papers which so often formed the introduction to subjects that were brought before them, and they heard of them in the room of the Society of Arts. Then who were they who dealt with the subject of fish. They had in the fish the wonderful property of applying energy with the greatest possible efficiency, and all their Mechanical Engineers were doing their very utmost to apply the principles of fish to this application of electric lighting. When they came to *entrées*, they dealt with those light and gentle things which formed a kind of substratum for something better to come ; and here they must classify the Naval Architects and Iron and Steel Institute, because they dealt with such things as shells, explosives, torpedoes, and gentle things of that class. But when they came to meat—the solid substratum on which they all existed, that institution that applied the great forces of nature to the wants of mankind, the Institution of Civil Engineers—then they came to deal with that society to which they were so intensely indebted for their home and for many kindnesses. Now, when they came to the next head, that of the "sweets," he could only think of the British Association ; and in connection with the British Association, the only thing that came to his mind was a plum-pudding, for a plum-pudding was made out of many sections ; and there was one section, Section G, out of which electrical engineers very often pulled some very good plums. But when they came to the "dessert," the *finale*, then he could only speak of themselves, for there they had only lightness and grace. They wafted sighs from Indus to the Pole. They sent messages of peace and goodwill along the silent wires from zone to zone. They carried health and comfort to their homes, their establishments, and they were doing all that they possibly could to utilize the great forces of nature that were now running to waste. Here they were assisted by everyone of those "kindred societies." There was not a single society that he had named that was not helping them to make use of those forces to further the object which they had in view, namely, to apply the great forces of nature to the wants of man. There was one society that he had forgotten, that kindred society that picked up crumbs that fell from the rich man's table, and he did not think that they ought to leave out of the kindred societies the old and young students who were practising to take part in their future discussions. There was one point that he must add supplementary to the remark made by the President of the Royal Society, and that was, that he was going to divulge the open secret. The open secret that he was going to divulge was this, that there was every reason to believe and hope that the next President of the Royal Society would be one who belonged to every kindred society he had named, who was their President last year, and whom next year they should hope to have amongst them to respond as President of the Royal Society to the toast, and that was Sir William Thomson (cheers). He proposed to couple with this toast the representative of the Institution of Civil Engineers, one of its past Presidents, Mr. George Berkley.

Mr. GEORGE BERKLEY, in responding, said that he felt that the health of the Kindred Societies being proposed showed that there was a genial, kind, and cordial feeling among those societies, and he felt deeply that the existence of that cordial and good feeling was essential to their success. He might refer to the communications that had taken place within the last few years between the engineers of America and the engineers of Great Britain. Two years ago they had a visit from 250 of those engineers. They were delighted to see them, to entertain them, with a hospitality which he was sure was appreciated. He had just returned from a visit to America with at least 250 members of the Iron and Steel Institute. He need not tell them that they had been received with the most generous and magnificent hospitality, and that intercourse had produced on both those visits the best possible feeling between the engineers of the two great countries. Prejudice had been cast aside ; breadth of views had been obtained ; great knowledge of the conditions under which the two countries and the engineers

Digitized by Google

of those countries worked had been acquired. He could not but feel that that sort of intercourse was of great value, not only to their profession, but to the two countries that had been represented on those occasions. He also for one moment wished to refer to the question of the electrical progress in the two countries. No one could come back from America without feeling that their dear old country was somewhat behindhand in the adoption of the advantages which electricity presented to them, and he trusted; and had no doubt, that we shall soon make up lost ground, and be equal to our good friends on the other side of the Atlantic (applause).

The PRESIDENT next proposed "Our Guests," coupled with the names of Sir Richard Webster, Q.C., M.P., Attorney-General, and Prof. Dr. Coleman Sellers, member of the International Niagara Commission. He saw amongst their guests that evening there were two gentlemen who had attained to the highest eminence in different lands and different walks of life. Sir Richard Webster was a gentleman whom many of them had learnt to fear as cross-examining counsel almost as much as to admire when he was on one's own side. Sir Richard Webster, he had no doubt, would tell them that he knew nothing about electricity. They had had that already contradicted that evening. They would find that he knew a very great deal about it, indeed, and he was happy to say that he had begun to admit that he knew something about electricity, for he had consented to join their institution. Dr. Coleman Sellers, having attained to the highest eminence in other branches of engineering, had now devoted his talents to electrical engineering, and had applied them to a particular problem. That problem was the utilisation of the vast energy which was going to waste in the Falls of Niagara.

Sir RICHARD WEBSTER, in response, said: You have heard from no less an authority than the Postmaster-General who knows me as an old friend, and I regret to say you have heard him remark that my law is as bad as my electricity. I confess I shall go out of this room a sadder and, I trust, a wiser man, determined by some process or other to imbibe, if not a little more law, yet a little more electricity, which may conduce to a "higher standard" up to which I may direct my law. My excellent friend, Dr. Hopkinson, has spoken of me in very kindly terms. It is the fact that there are many in this room whom I have met in friendly combat. I have always liked to see them on my side if I could, and if they were against me I regarded it as a temporary misfortune, so far as I was concerned. I confess that I never knew before that I was going to join this Society because I was an electrician. I was asked by no less a person than Sir David Salomons, whether I would consent to be a *member*—to be put up. "Why," I said, "I thought you only admitted great electricians;" to which he replied, "Oh, yes; we let in duffers like you as well" (laughter). Well, on those terms I felt that there was some possibility of my not being blackballed. It is not for that reason only that I consented, for I have a very great desire to improve my knowledge of electricity, and I think if I was to dine here more frequently, and sit between Mr. Latimer Clark and Mr. Preece, that some "secondary currents" might possibly find their way into my miserable "insulated body." I suppose I ought to say perfectly "insulated body," so far as electrical bodies are concerned. I confess—what with the rheostats, the volts, and amperes, and relays, and all those dreadful words, which no sooner come into my head than they go out again—I have made but a sorry figure, and I have tried to find out the reason. Years ago I studied "secondary batteries," or tried to, and thought that they just fitted my constitution; but my excellent friend, Mr. Crompton, said to me: "You are no good; you charge very well, but you discharge much too rapidly" (laughter). Then I tried to understand "transformers" and "high potentials;" but it was no good, and I assure you, although I am speaking on behalf of myself, I believe I represent the feelings of the guests at the same time in this matter. I am at the present time in a state of despondency, because, studying those abstruse problems, I met Prof. Forbes, and I explained to him my condition; and after looking at me, he said: "Why, it is no good. You are wound the wrong way; you want re-winding" (laughter). Well, gentlemen, I am afraid that some of you electricians will think me past praying for. Still, I have hope that some yet to be discovered subtle agency will possibly do something for me; and I have thought that I might venture to ask for admission within these sacred portals. I am sure that many of the guests for whom I have been supposed to speak appreciate what I am going to say. I can assure Dr. Hopkinson that I address him as an old friend, and that it gives me great pleasure to be here, and I am sure that the influences, electrical or otherwise, which have been applied to our constitutions, will have left good impressions, and we shall be glad to be your guests on any future occasion.

Dr. COLEMAN SELLERS also responded. He was glad to have the opportunity of meeting face to face men whom he had only known by name. There had been some words spoken about the manner in which the English engineers appreciated the courtesies extended to them in America. He could assure them there was nothing which gave the Americans so much pleasure as to meet their friends from England in the United States, and to pay back in some slight measure the many favours which had been granted to them when they came to England. This summer he spent his holiday in London—not London-on-Thames. When there, he was met by a telegraph message from New York, asking him to report on a special subject, which was the comparative cost of the transmission of power by electricity as compared with the primary generation by steam at any fixed location. He was told to go to Niagara Falls, and he visited the place and reported. That report had been submitted to some engineers in America, and it was of such a nature that certain capitalists decided to go into the thing, and a syndicate was formed to advance the money and to endeavour to carry out Sir William Thomson's prophesy, that in the near future New York and other cities were to draw their power and heat and light from the great Falls of Niagara, where so much power was now going to waste. The Company that he represented now in England was proceeding in a very moderate way. They did not think of taking from the Falls more than a trifle of 120,000 horse-power. It required some millions of dollars, they might say, to extract that power, but in order that it should be done in the wisest and best manner, it was proposed that he should come to England. He had not been sent to raise money for this enterprise. The Company having charge of this attempt to utilise the Falls of Niagara had sent him to Europe to get the means to carry it out, and to get the brains necessary to do it. In America they thought they knew a great deal, but they had the knowledge of the fact that they knew a very little. They wished to start this Company on a basis of economy, and on the very highest plane of the arc. That this was an enterprise worthy the consideration of engineers was shown by the readiness with which such men as Sir William Thomson and Prof. Unwin gave themselves to it in the capacity of being members of the International Niagara Commission. Such men would not be induced to go into it but for the great interest there was in the gigantic scheme, and therefore he felt somehow as if when he was among the engineers of England he was with his own personal friends. He looked about him and saw faces different in no way from those faces he saw in America; they were all of the same blood. It happened for himself that it had been more than two hundred years since his people had arrived in America, and yet there was not one drop of blood in his body that was not English. They were brothers, and as brethren, they must work in this great invention.

The Right Hon. CECIL RAIKES, M.P., Postmaster-General, then proposed "The Institution of Electrical Engineers," coupled with the name of the President. The right hon. gentleman said: Gentlemen, your kindness has devolved upon me the duty of proposing that which you have just heard is the toast of the evening. I can only regret that, with the modesty which always accompanies true genius, you have thought it right to place the toast of your noble selves at the back end of the evening's programme, yet I think it right just to dwell for one or two minutes upon the facts connected with this institution, which, I think, are full of significance and interest. As the last speaker has pointed out, you are a young society. It was only in 1871 that this institution was founded, and I find that in that year you numbered what was a very respectable number for a beginning, no less than 268 members; but that in the year which is just elapsing that number has risen to 1,738, an increase of 1,470—that is to say, more than five times as many members of this society in the present year than there were at the time when it commenced. But what is even more remarkable is this: I find that in the first year of your existence you had two only very courageous young men, who enrolled themselves as students in this institution, but that the number has increased until in the present year there are no less than 102. That while the members of the Society have increased in the ratio of 5 to 1, the students have increased in the ratio of 50 to 1. Of course, that points a very obvious moral. The amount of work for electrical engineers has been increasing with giant stride, and there is every reason to anticipate that in the immediate future it will increase at even a greater rate. I find, whilst on the subject of the students, that a gentleman who has been referred to this evening as a true friend of this institution, Sir David Salomons, has founded an exhibition for a student in electrical engineering, and I feel very little doubt that at no distant time his example will be followed on a very large scale by those who come to realise, as he has done, how greatly this science in the future will conduce to the welfare and prosperity of our country. You are still indebted to the older but friendly Institution of Civil Engineers for certain privileges and advantages which they have been pleased and proud to offer you. I think that it is a very gratifying fact to find the elder sister holding out her hand to the younger sister, and encouraging her in the great efforts which she is making in her own particular branch of applied science. Thanks to the electrical engineers, there is now a system of submarine cables of not less than 120,000 miles in length, and there are in the limits of these islands no less than 2,000,000 miles of the telegraph system. That did not, he believed, include the telephonic system; but although that was a burning question—as to which, perhaps, he should say as little as he possibly could—there could be no doubt that with the expiry of the telephone patents, in the course of the next year or two, a fresh field would be opened for the inventive genius of Electrical Engineers. Now, having very amply endeavoured to render my tribute to the great work that you have done, that you are doing, and you will do, you will allow me to pass to the more personal part of the toast, as I have to connect with it the name of your excellent President. A few years ago we were told that the old Universities were quite played out; that what we taught at Oxford and Cambridge was of no practical use to any sort of man who went out into the world to make his own career. I think recent events have rather falsified that assertion. I should think that this is the day of Senior Wranglers. My excellent friend and colleague, the President of the Royal Society, is, of course, a Senior Wrangler. That might under any state of affairs have been perhaps expected. But Senior Wranglers have shown that the training which they receive at Cambridge may be utilised in other walks of life. The two most efficient additions to the Equity Bench of late years have both been Senior Wranglers, and the President of your Society, who sits here, is also, as you know, a Senior Wrangler. In your President you have a very happy representative of that union of moderate pursuit of the ordinary recreation of life with the most studious and persistent endeavour to fit himself for the highest place in its higher branches. I beg to ask you to drink the health of your Institution, may it long flourish and extend its borders. I ask you to join with the toast the health of your President, Dr. Hopkinson (applause).

The PRESIDENT, in reply, said: The place and value of such a Society as ours is not to be entirely measured either by the number of its members or by its income, but rather by its usefulness in recording new knowledge and disseminating that knowledge abroad. Measured by this standard, surely our Institution must take very high rank. With the recent rapid

Digitized by Google

development of heavy electrical engineering, it may readily be supposed that our Institution has had a very important work to do, and I venture to claim that that work has been right well done. In spite of electric lighting having been hampered by the low price of gas and the electric transmission of power in some measure by the absence of water power, the work that has been done in this country, I venture to say, has been well done. The study which Englishmen have devoted to the science of electricity in its application to lighting and the transmission of power has placed this country in the foremost rank in this connection. I am sure that we occupy a post as eminent in this connection as in the past time was the case in connection with ocean telegraphy. I thank you, Sir, for the kind way in which you proposed the toast of the Institution. I thank you also for the very kind way in which you have spoken of myself this evening (applause).

The company then separated.

## AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *November* 14, 1890.

**New York Elevated Roads.**—Nothing has been done recently concerning the application of electric power to the elevated roads, although the West End Railway Company of Boston, which is about to build an elevated line, proposes to use electric traction exclusively.

**Edison Arc Light Machine.**—This Company is about to enter the arc lighting field with a machine of its own. Until very recently it has carefully avoided exploiting an arc system ; but about a year and a half ago it obtained the right to use the Sperry arc machine for its installations, and the present outcome is a near relative of that excellent machine. The same general form of construction has been employed, but the interior pole-pieces, always a questionable advantage in the Sperry system, have been dispensed with, and the regulator has been somewhat changed, although the same principle of shifting the brushes has been adhered to. The first of these new machines will be installed within a few days. The Edison Company's stock was attacked vigorously on Wall-street this week. During the period of depression it had held up remarkably, but finally, in the general attack on the Villard securities, it dropped more than 20 points. The confidence of the general public, however, in its real value was shown by a very sharp rebound within 48 hours, so that at present writing it has nearly regained the former quotations.

**A Westinghouse Power Plant.**—This Company has been displaying its usual activity in exploiting its street railway system. One of the most novel applications of the Westinghouse apparatus is now being installed in Telluride, Col. It is a mining country, where plenty of water-power is available, but the distances over which power must be transmitted are great. There is now being erected a Westinghouse power plant on the alternating system to transmit at first 100 horse power over about three miles, and later large additional amounts up to distances as great as fifteen miles. The generators used are the Westinghouse standard alternating type, and the motors are similar machines, to be run synchronously, and started by independent self-starting motors on the same circuit. Once up to speed, the large alternators will take their load with the greatest readiness. The power circuit will be of bare copper wire carried on rather high poles, and inasmuch as the country is sparsely settled, such a proceeding is safe. The plant is driven by Pelton water-wheels, under a head of nearly 500ft.

**New York Street Lighting.**—The electric lighting situation in New York City remains for the present unaltered. Mayor Grant, who has rendered himself thoroughly obnoxious to electrical interests during the last two years, has unfortunately been re-elected, so that the difficulties of the past will be in no wise lessened during the coming administration. The difficulties with the subway system are growing to be particularly annoying, and it is possible that even the present City Government may be compelled to take some measures for the relief of the electric companies from subway extortion. So great has been the demand for electric lighting that at a recent secret meeting of the Board of Electrical Control it was found necessary to allow the erection of certain pole lines.

## SCANDINAVIAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

COPENHAGEN, *November* 22, 1890.

The State telephone between Stockholm and Malmö, according to a telegram just received, has to-day been tested with satisfactory results. This is a very important installation right across the broadest part of Sweden, and the Swedish capital is now in telephonic connection with the two principal towns on the west coast, Gothenburg (240 miles) and Malmö (340 miles). I may have occasion to refer again to the Stockholm-Malmö line in a future letter. The manner in which the telephone is extending in Sweden is well worthy of attention. At the beginning of the present year the State telephones in Sweden comprised 3,338 separate lines, with an aggregate length of 8,843 kilometres. The number of telephones was 3,925, of which 135 were at telegraph or central telephone stations, and 3,790 were subscribers'. Together with private telephones, the total length of telephone lines was 46,090 kilometres at the beginning of the year, and there were 463 central stations and 18,854 subscribers. Of the above central stations the State owned 39. During last year the State expenditure upon telephones amounted to 416,813kr. (1kr. = 9½d.), and altogether up to the end of the year 1,386,535kr. The more important State telephone installations last year were the Stockholm, Gothenburg, Uddevalla lines, with an aggregate length of 624 kilometres.

During the year the State telephones received 46,021 telegrams, and were the medium of delivering 43,847 telegrams ; the number of subscribers' conversations amounted to 6,728,313, and conversations against special payment amounted to 56,468. The State telephones last year yielded 369,023kr. gross receipts, working expenses amounted to 180,187kr., and 58,168kr. were applied to a sinking fund. The surplus was thus 130,669kr.

Several Scandinavian towns have lately claimed the honour of having the largest number of telephones in proportion to their population of any town in Europe or, perhaps, even in the world. Christiania first entered the list, thinking her 2,600 subscribers, out of 140,000 inhabitants, that is, between 18 and 19 to every 1,000 inhabitants, was at the top of the tree. Stockholm has, however, 6,318 telephone subscribers out of 240,000 inhabitants, or 26 subscribers to every 1,000 inhabitants, but even this has been beaten by a small place. Ballnös, which, with barely 1,000 inhabitants, has 52 telephone subscribers.

The application of electricity is, however, by no means confined to the telephone, installations of various kinds having of late been taken in hand. I have already mentioned one electric railway opened in Sweden not long ago, and this is likely soon to be followed by several others. Concession has been given for an electric railway in Stockholm, from the Gustaf Adolf-square to Djursholm, and another has already been taken in hand between Karlslund and Örebro. Electricity is also likely to be gradually adopted as a means of power in a number of industrial establishments, owing to the many waterfalls which exist in Sweden. At some mines in the Vörmland district electricity is about to supersede steam. There is a waterfall at some 10,000ft. distance, which has hitherto been useless, but which will now be utilised, and the installation will also comprise one for electric light in the mines. At Ballnös, Sweden, a small electric central station has been erected, the water of the Ljusnan river supplying the power. The turbine is of 35 horse-power, and the dynamo can supply current to 400 16-candle lamps. The brewery, the inn, the railway, &c., will be lighted, and there are two arc lamps for the street.

## CORRESPONDENCE.

### AN IDEAL PHYSICAL LABORATORY FOR A COLLEGE.

TO THE EDITOR OF THE ELECTRICIAN.

SIR : The enclosed note from Prof. Ewing, modifying one of my statements in connection with "An Ideal Laboratory" on p. 32, is worth inserting.—Yours truly, OLIVER J. LODGE.

*Extract.*

"By-the-way, I see you say apropos of laboratories, that absence of magnetic materials is a troublesome fad. I agree, with an important qualification. You should have no iron about the place *that is liable to large variations of temperature.* No iron hot water pipes ; no iron grates ; no iron stoves. When I began working in Japan I had what they call a drum stove made of sheet-iron, that got red hot now and then. In a few minutes it would wholly change the magnitude and direction of the local magnetic field, making magnetometer and galvanometer work impossible for many yards round. Naturally it had to be put out, and one had to take to working in one's ulster." J. A. E.

University College, Dundee, Nov. 15, 1890.

## PHYSICS v. METAPHYSICS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I do not think you have said, in your leading article for this week, a word too much against those pseudo-philosophers who are as poor metaphysicians as they are bad physicists. All true metaphysicians would be delighted to have "fashionable philosophy" and "amateur metaphysics" slaughtered once and for all.

It seems to me as if there were some hope of agreement between you and true metaphysicians, if you will not so much keep off each other's grounds as respect each other's points of view, and make allowance for each other's terminologies. As you suggest the hypothesis that electricity is the mode of action of something, the metaphysicians may claim to take matter as the mode of action of consciousness.

Mr. Heaviside's *obiter dictum* that "there are only two things going, matter and energy . . . . . . all the rest are moonshine," would be instantly swooped upon by metaphysicians as a bit of unsurmountable dogmatism, and an over-stepping of his province, particularly if he meant that where these two things are going is the whole universe, including man and the mind of man. "Consciousness returning into itself," or some such (to Mr. Heaviside, possibly) gibberish phrase, would be the strictly metaphysical-scientific way of expressing the effects which you call matter and energy. It is merely the tendency of knowledge to simplify, to reduce many forces on to a few, or many gods to one. It may be hoped, therefore, that the great division or dualism of physics and metaphysics, both alike capable of being true philosophies and true sciences, will in time be overcome, if the students of each will be patient with one another and humble of themselves.—Yours, &c., I. F.

November 26th.

## BOURSEUL'S SPECULATIONS ON THE TELEPHONE.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Referring to the last clause of Mr. Latimer Clark's letter to your paper, published in your issue of October 31, 1890, in which he says it would "be interesting to find the original source from which Count du Moncel derived his account of Bourseul's telephone," I am glad to be able to furnish him the information desired.

Bourseul's original letter on this subject, dated August 18, 1854, and having his signature appended to it, is to be found in *L'Illustration*, Paris, August 26, 1854, p. 139. This information is not quite novel, but since so distinguished a chronologist as Mr. Latimer Clark has overlooked, I may be pardoned for believing that it will be fresh also to many readers.

I cannot, however, coincide in the opinion of Mr. Latimer Clark that if Bourseul "had only put his ideas to the test of experiment, we should have had the telephone in 1854." If he will look over the Du Moncel account once more, he will see that Bourseul says, "I *have* made some experiments in this direction." But Bourseul contemplated a transmitter which would, as he says, "alternately make and break the currents from a battery." Reis exhaustively explored this plan, and failed. Bell forsook this plan and worked in an opposite direction, and succeeded; and it was because he forsook the idea of intermittences that he succeeded. It is easy to speculate, but difficult to achieve; and although the world knows that before Bell there was no speaking telephone, and that as soon he made known the art of the electrical transmission of speech they appeared by thousands; yet it is true that the failures of the men who were working in the direction of failure, and failed, are set up on a pedestal of equal height as the success of the man who worked in the direction of success, and succeeded.—Yours truly, THOMAS D. LOCKWOOD.

Boston, Mass., U.S.A., November 12, 1890.

## OIL INSULATION.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: As the employment of oil insulation for use in connection with currents of high potential seems to be exciting some interest at the present time, the following experiments on the relative sparking distance between bare conductors in air and immersed in resin-oil respectively, which I have recently made in connection with some apparatus for Lord Armstrong, may, perhaps, be worth publishing.

A 12in. induction coil, kindly lent for the purpose by Mr. Apps, was employed to produce the sparks, the terminals of this coil being connected to a movable point and ball forming the air gap electrodes, and also in parallel with these to a point and disc contained in a large vertical test tube filled with resin-oil, the point being at the bottom and connected by a wire sealed through the glass, and the disc being fitted to a sliding rod so that the distance between the two could be varied as required.

As shown below, this variation was made by tenths of an inch up to half an inch, and then by half inches at a time, the air electrodes being in each case adjusted till the spark took place indifferently through either oil or air.

| Spark in air (inches). | Spark in oil (inches). | Ratio. |
|---|---|---|
| 1· | ·1 | ·1 |
| 1·125 | ·2 | ·177 |
| 1·5 | ·3 | ·2 |
| 1·5 | ·4 | ·266 |
| 1·75 | ·5 | ·285 |
| 2·75 | 1·0 | ·363 |
| 5·125 | 1·5 | ·292 |
| 7·875 | 2·0 | ·253 |

On increasing the oil gap above 2″ the spark preferred to perforate the glass in two places and run down outside the tube rather than pass through the oil.

Though the above results seem to be somewhat irregular, they were carefully obtained, and it appears from them that for potential of this amount the sparking resistance of resin oil is from ten times to rather less than three times that of air. These results, especially those obtained with the higher potentials, seem to show that the insulation resistance of resin-oil is not altogether so high as has generally been believed, though it is probably high enough for all commercial purposes.

Some experiments were also tried with ordinary paraffin oil, and the opposition that this substance offered to the sparking was found to be about one-half that of resin-oil as above.

I may mention in conclusion that according to De la Rue a 1in. spark in air represents a difference of potential of 23,400 volts, and 163,600 volts for 7in.—Yours truly,

London, November 24, 1890. A. A. CAMPBELL SWINTON.

# LEGAL INTELLIGENCE.

### Dickins and Another v. Metropolitan Electric Supply Company (Limited).

In the Queen's Bench Division on Wednesday last, the case of Dickins and Another *v.* Metropolitan Electric Supply Company (Limited) came before Mr. Justice Stephen and a special jury. This was an action brought by Messrs. Dickins and Jones, drapers, &c., carrying on business in Regent-street, against the defendant company to recover damages for alleged breach of a contract to supply the plaintiffs with electric light. The defendants denied the alleged breach, and relied upon the provisions of a statute which they said justified their action.

Mr. Jelf, Q.C., and Mr. McCall appeared for the plaintiffs, while Mr. Lumley Smith, Q.C., and Mr. R. S. Wright represented the defendants.

Mr. McCALL, in opening the case for the plaintiffs, said that prior to 1888 his clients' premises were supplied with electric light from the Grosvenor Gallery. Subsequently they were supplied by Mr. Pritchett, of Rathbone-place, the price being so much for each lamp according to the candle-power. The contract was that the light was not to be cut off unless three months' notice were given. Afterwards the defendant company sent a notice to the plaintiffs to the effect that they had purchased Mr. Pritchett's business, and submitted to them certain terms, which were never actually signed. The plaintiffs continued to supply the light and to collect the amounts due in respect of it until the light was cut off. About September, 1889, the plaintiffs were informed that, owing to an Act of Parliament which had been passed, and of certain Provisional Orders included in the Act, the defendant company would no longer be able to supply that particular district, and they were advised by the defendants to communicate with Major Waller, of the London Electric Light Supply Corporation. The defendant company, however, added, "Of course, we will continue to supply you until we are turned out by force." The plaintiffs' manager called upon

Digitized by Google

the defendant company, and they arranged to continue the supply until the new company was in a position to supply the district. In October complaints were made by the plaintiffs with regard to the light, and then the defendant company replied that they were only lighting plaintiffs' premises on sufferance, and that they might be turned out at any moment. On November 16th, without any warning whatever, the supply was cut off, and the plaintiffs' premises were left in darkness. The defendant company, in answer to the action, said they were justified in doing what they did by reason of a clause contained in an Act of Parliament passed in 1889, confirming certain Provisional Orders made by the Board of Trade, under the Electric Lighting Acts, 1882. Section 6 enacted "that the undertakers shall not at any time after the commencement of this order supply energy or (except for purposes of this order) erect or lay down any electric lines or works beyond the area of supply, otherwise than under the authority of Parliament or under a license granted by the Board of Trade under the principal Act. Provided that where the undertakers were, on May 28, 1889, supplying, or under any binding agreement to supply, energy to any premises beyond the area of supply, they may continue to supply energy to such premises until September 29, 1890, or, in case any such notice as hereinafter described is served upon them, until such earlier quarter-day as may be mentioned in such notice." In consequence of the action of the defendant company, the plaintiffs had to light their premises with gas for some time, and their goods became greatly damaged.

Mr. HENRY DICKINS, senior partner in the firm of Messrs. Dickins and Jones, gave evidence in support of counsel's opening statement. He added that nearly the whole of his premises were supplied with the electric light. He received no notice that the light was to be cut off on November 16th. He had sustained considerable loss in consequence of the action of the defendant company. The gas injured the stock and made the premises dirty. He had had to pay Messrs. Verity £484 for electric light plant. Witness, in cross-examination, said he was aware that London had been divided into districts for electric lighting purposes, that the defendant company were restricted to Marylebone, and that two other companies supplied the district, of which Regent-street formed part. Mr. Lane, his manager, did not inform him that the existing cable, which brought the electricity from Rathbone-place, was not according to the new regulations. He did not know that unless the defendant company complied with the Board of Trade's regulations they had no power to supply them with electric light. He offered to pay £25 towards a new cable.

Several *employés* of the plaintiffs were called to show the serious effect which the alleged breach of contract had upon the plaintiffs' business and goods.

Mr. JOHN COLES, manager to Messrs. Verity, gave evidence to the effect that he superintended the fitting up of the electric light apparatus at the plaintiffs' premises. The work was completed by the commencement of February last. If the plaintiffs had received three months' notice, his firm could have fitted up the necessary apparatus for them within that period. In cross-examination, witness said he could have fitted up the apparatus within two months.

This concluded the plaintiffs' case.

Mr. LUMLEY SMITH, on behalf of the defendant company, submitted that there was no evidence of any contract to support the plaintiffs' case. Mr. Pritchett had not been supplying the electric light under any contract, because the form of the contract was never agreed to. Either party could at any moment, at will, have determined the arrangement. The defendant company went on supplying the plaintiffs with electric light upon the same terms as Mr. Pritchett had supplied them, but they were not bound to give plaintiffs any notice, as the plaintiffs had failed to agree to the form of contract sent into them by the defendant company.

Mr. JELF argued that there was ample evidence of a binding agreement between the parties. If no notice was mentioned in the contracts a reasonable notice must be inferred. Three months' notice was mentioned in the written bargain which the defendant company sent in to the plaintiffs, and he (the learned counsel) thought that was a fair notice.

Mr. LUMLEY SMITH said if the plaintiffs had refused to accept the light, the defendant company could not have compelled them to do so.

Mr. JELF said the contract was accepted and acted upon, though it was not signed.

His LORDSHIP said there never was a written contract between the parties at all, and he did not think there was any evidence of a contract arising from a matter of fact. Therefore he should enter judgment for the defendant company, with costs.

A stay of execution pending an appeal was granted.

### London Electric Supply Corporation v. Crookshank.

In the Queen's Bench Division, on Wednesday last, Mr. Justice Day, sitting without a jury, had before him the case of the London Electric Supply Corporation *v.* Crookshank, which was an action by the plaintiffs to recover from the Committee of the Pall Mall Club the sum of £120 for electricity supplied to the Club under a contract. The plaintiffs' case was that the defendants agreed to pay for the electricity supplied to the Club at the rate of £1 per annum for each lamp of 10 candle-power until a meter was fixed, and that then they were to pay the meter rate. The charge per lamp was considerably under the market value of the current supplied. There was a good deal of delay in fixing a meter at the Club, as the plaintiffs had some difficulty in obtaining a good instrument. A meter was finally fixed, and when the plaintiffs sent in their account for the electricity consumed according to the meter rate, the defendants refused to pay, and ultimately the plaintiffs cut off the supply. The defendants denied that the contract was that they were to pay the meter rate.

Mr. R. T. Reid, Q.C., and Mr. Lynch appeared for the plaintiffs, while Mr. Winch, Q.C., and Mr. Lyttelton represented the defendants.

At the conclusion of the evidence his LORDSHIP said it was greatly to be deplored that persons who made bargains which were not to be carried out at once did not take the trouble to put them into writing. He (the learned judge) had looked at the correspondence very carefully, but that did not disclose a contract by the defendants to take the electricity by meter. Though there was no doubt that the defendants had had a benefit which the plaintiffs did not intend to confer upon them, he was bound to decide the case according to the evidence put before him. He did not find that there was any agreement by the defendants to take the electricity according to the meter scale, and therefore he entered judgment for the defendants, with costs.

### Woodhouse and Rawson Electric Supply Company of Great Britain.

In the petition for the winding up of this Company, Mr. Graham Hastings, Q.C., who represented the petitioner, applied on Saturday that it might stand over, as the parties were negotiating for a settlement.

Mr. BUCKLEY, Q.C., who appeared for the Company, not raising any objection,

Mr. Justice STIRLING allowed the petition to stand over for a fortnight.

## TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning.*]

TENDERS WANTED.—The Pretoria Lighting Company (Limited) announce in our advertisement columns that tenders for (1) five multitubular boilers, (2) five engines, and (3) complete electric lighting plant, will be received until noon on Saturday, December 20, 1890, at the offices, 29 and 30, Holborn-viaduct, London, E.C., where plans of Pretoria and of the proposed works can be seen.

ROYAL NAVAL EXHIBITION, 1891.—By an advertisement in our columns to-day, intending exhibitors are reminded that all applications for space must be received by the 30th inst. Particulars may be obtained of the hon. secretary, Capt. Alfred Jephson, R.N., 6, Craig's-court, London, S.W.

MESSRS. BENTON AND STONE.—This firm have now removed from Mandril Tube Works to their new premises, Aston Brook Tube Mills, Birmingham.

REMOVAL NOTICE.—Messrs. Nalder Bros. and Co. notify their removal from Horseferry-road, Westminster, S.W., to more commodious premises at 16, Red Lion-street, Clerkenwell, E.C. Their new telephone number is 6,770.

FOWLER-WARING CABLES.—The Fowler-Waring Cables Company have sent us specimens of the cables used in the South London Railway. The main cable consists of 61 strands of No. 14 S.W.G., forming a core of nearly three-quarters of an inch diameter, the sectional area of copper being ·3067 square inch. It is served with about 170 mils thickness of insulation, and is protected by a lead covering of about 130 mils, and is finally taped and compounded, the overall diameter being about 1⅛in. Specimens have also been sent us of a 30-wire lead-covered telephone cable, the conductors being No. 18. This Company is devoting much attention to the production of wires for aerial and house purposes, and are laying down a large plant at their Woolwich works for all kinds of wires and cables, lead-covered, rubber-covered, vulcanised, &c.

LINESMAN'S TOOLS.—Messrs. W. Kücke and Co., of Elberfeld, Germany, are the makers of a handy wallet containing twenty-six tools in constant use by linesmen, making, when folded up for carrying, a compact arrangement weighing only 3¼lb.

## PATENT RECORD.

### APPLICATIONS FOR PATENTS.

NOTE.—*The undermentioned applications are not open to public inspection until after the acceptance of the complete specification. The names within parentheses are those of communicators of inventions.*

November 3, 1890.

17,976. G. QUICK. Bournemouth. Improvements in means for firing ordnance charges by electricity.

17,987. W. R. VARNEY. Weston-super-Mare. Improvements in electro-medical appliances.

18,034. G. F. REDFERN. London. An improved electric switch (A. Schirner, Germany).

November 10, 1890.

18,076. J. Y. JOHNSON. London. Improvements in sockets or holders for incandescent lamps (J. W. Collier, United States).

18,088. J. E. KINGSBURY. London. Apparatus to be employed at telephone switch-boards (The Western Electric Company, United States).

November 11, 1890.

18,103. C. E. Knowles. Manchester. Improvements in electric switches.

18,158. C. H. Gray. London. An improved electric pressure indicator.

18,163. M. Humm. Forest Hill. An appliance for the administration of electricity to the human body in Turkish baths.

18,180. Sir C. S. Forbes, Bart. London. Improvements in primary batteries, and in apparatus connected therewith.

18,186. H. H. Lake. London. Improvements in electrical measuring instruments (E. Weston, United States).

18,195. A. E. Cotterell. Moseley. Improvements in telephonic apparatus for minimising or overcoming inductive and other undesired electrical disturbances in telephonic circuits.

November 12, 1890.

18,206. H. Davis and A. H. Stokes. London. Improved communicator for dynamo-electric generators and motors.

18,217. D. Maclean. Sydenham. Improved protector for telegraph, telephone, and other electric instruments.

18,247. J. D. F. Andrews. London. Improvements in fittings for electric lamps and their conductors.

18,243. J. A. Mays. London. Improvements in electrolysis.

November 13, 1890.

18,266. H. J. Davies and L. B. S. Dutson. Walsall. Improvements in electric tramways and electric conduits.

18,270. J. M. M. Munro. Glasgow. Improvements in electrical conduits and conductors.

18,292. B. M. Drake and J. M. Gorham. London. Improvements in switches for electrical purposes.

November 14, 1890.

18,339. W. R. Lake. London. An improved process and apparatus for the production of oxygen and hydrogen by electrolysis (H. Dehuard, France).

November 15, 1890.

18,409. L. A. Davies. London. The improvement of electrical switches and other electrical apparatus.

18,412. D. Robertson. Glasgow. Improvements in electric batteries and lighters for cigars and other purposes.

18,423. J. P. Bayly. London. An improved coupling for electric wires (J. Hinphey and B. Matthews, United States).

18,470. A. F. Purdy. London. Improvements in telegraph keys. (Date applied for under Patents' Act, 1883, Sec. 103, 15th April, 1890, being date of application in United States.)

November 17, 1890.

18,491. R. Kennedy. Kilmarnock. Improvements in dynamo-electric machines.

18,523. H. Zerener. London. Improvements in apparatus for heating, welding, or gasifying solid bodies by electricity.

18,537. E. S. Cook. London. Improved method of signalling on railways, and appliances connected for electrically operating same.

18,554. H. J. Pierce. London. Improvements relating to the fixing in insulating bases of blocks for connecting electrical conductors.

18,555. H. J. Pierce. London. Improvements in electrical switches.

18,556. H. J. Pierce. London. Improvements in electrical switches.

18,557. H. J. Pierce. London. Improvements in electrical switches.

18,558. H. J. Pierce. London. Improvements relating to electrical pendants and other portable or movable electrical devices.

November 18, 1890.

18,576. R. H. C. Nevile. Westminster. Improvements in apparatus for controlling electric currents.

18,587. J. Platt. Gloucester. Improved form of electric locomotive (F. W. Dean, United States).

18,589. W. H. Waddell. London. Improvements in electric railway signals.

18,625. H. H. Lake. London. Improvements in and relating to apparatus for use in electric welding, forging, and other metal-working operations (H. Lemp, United States).

18,631. H. H. Lake. London. Improvements relating to the welding of metals by electricity (E. Thomson, United States).

18,638. E. Hartmann and W. Braun. London. Improvements in electricity meters.

18,660. A. J. McGeoch. London. An improved terminal for electric lamp holders.

18,661. J. T. Niblett. London. Improvements in the construction of plates for secondary batteries.

18,663. An improved instrument for removing the covering from insulated wires.

November 19, 1890.

18,695. J. H. Holmes. Newcastle-on-Tyne. Improvements in armatures for dynamo-electric machines.

18,699. W. H. Thomson and H. von Kohler. London. Improvements in electric circuit closers or push buttons.

November 20, 1890.

18,776. A. T. J. Cutmore and F. H. Bointon. London. Electric telegraphic communication between termini, intermediate stations, &c., and railway trains or vehicles in motion.

18,791. O. Imray. London. Improvements in fixing for exposed telegraph wires to insulators (J. U. Baptista, Brazil).

18,796. J. Benford. London. An improved locking sash fastener and electrical alarm and indicator for windows, doors, and like purposes.

November 21, 1890.

18,836. W. Friese-Greene. London. Improvements in meters for measuring electricity.

18,858. W. C. Hunt. London. Hunt's hygienic electric boots and shoes.

# COMPANIES' MEETINGS & REPORTS.

## The Montevidean and Brazilian Telegraph Company (Limited).

An extraordinary general meeting of this Company was held at the offices, Langthorn House, Copthall-avenue, on the 25th inst., Dr. Cameron, M.P., in the chair, to consider the following resolutions :—

"1. *That the Company be wound up voluntarily under the provisions of the Companies' Acts.*

"2. *That George Fraser, F.C.A., be and he is hereby appointed the liquidator to conduct such winding up.*

"3. *That the Agreement submitted to this meeting, dated November 3, 1890, and expressed to be made between this Company, of the one part, and the Western and Brazilian Telegraph Company (Limited) of the other part (being an Agreement for the sale and transfer to the Western Company of the whole of this Company's undertaking), be and the same is hereby approved. And that the liquidator be and he is hereby authorised, in pursuance of Section 161 of the Companies' Act, 1862, and of all other powers enabling him in that behalf to carry said Agreement into effect with such modifications (if any) as he may think expedient.*

"4. *That the liquidator be and he is hereby authorised to receive, and when received, to distribute amongst the holders of Preferred Shares in this Company the rent accruing to this Company from the Western and Brazilian Telegraph Company (Limited), for the year ending December 31, 1890.*"

"5. *That the shares in the Western and Brazilian Telegraph Company (Limited) to be received as the consideration for the sale and transfer to them of this Company's undertaking shall be appropriated as follows:—*

"*To the shareholders in this Company in exchange for their shares at the rate of one share in the Western and Brazilian Telegraph Company (Limited) for each two shares in this Company.*

"*To the holders of Debentures of this Company in exchange for such Debentures at the rate of ten shares for each £100 of Debentures.*

Digitized by Google

*"To the liquidator in satisfaction of his remuneration and to the Directors and officers of this Company as compensation for the loss of their offices, 155 shares.*

*"The remaining shares to be sold, and the proceeds, after payment thereout of the expenses of the liquidation other than the liquidator's remuneration, to be distributed amongst the shareholders in this Company pro rata according to the number of shares held by them respectively."*

The SECRETARY having read the notice convening the meeting, as above,

Mr. CRISP (the Solicitor) read the proposed agreement between the Company and the Western Company.

The CHAIRMAN then said: I think I may take it that the very small attendance of this meeting shows that the shareholders have sufficient confidence in the Directors and are sufficiently satisfied with the arrangement which you have just heard read, for, though they have not turned up in large numbers at the meeting, they have sent us proxies representing 7,108 out of a total number of 8,314 Preferred shares and 599 out of a total number of 600 Deferred shares, giving a total very considerably more than three-fourths of the entire capital of the Company. That shows that the shareholders have taken a lively interest in the matter, though they are not largely represented in this room personally. Before this agreement can ultimately be adopted it must, as you know, be confirmed by a meeting to be held about a fortnight after this date, and in order that the shareholders, whom we shall ask again to support us at that meeting, may understand exactly how the matter stands, I propose making a statement on the whole subject, which we shall circulate among those who are not present to-day. In the first place, I would beg to remind you that if anyone feels inclined to cavil at the results of the working of this Company, the present Board is in no way responsible for those results. The present Board may be said to have come into office, and the present staff, the Secretary, and the solicitors, fifteen or sixteen years ago when the Company was in a very bad way financially. They had a very considerable amount of disagreeable work to undertake, and their first duty was to rescue the Company from bankruptcy. To show you the financial straits in which the Company then was, I may mention that although we attempted to raise money by an issue of Eight per Cent. Debentures, it was so insufficiently taken up that the Secretary and myself had to come to the assistance of the Company and advance a considerable sum of money in order to enable them to tide over the difficulties in which they then were. I would also point out that we have never had any opportunity of developing the resources of the Company or of pushing it in any way. We came into office finding ourselves bound hand and foot by agreement with the Platino Company, and, through them, with the Western and Brazilian Company. For some time past, as the shareholders are aware, negotiations have been going on between us and the companies with whom we have been working for the purpose of selling this Company to them. In 1885, the Western and Brazilian Company made us an offer, which was reduced to writing, which was agreed to by our Board, subject, of course, to ratification by the shareholders. We understood that the matter was practically settled. We called an extraordinary meeting of our shareholders, and that agreement was approved by them. We did not, however, by the advice of our solicitor, call the confirmatory meeting until the agreement had been ratified by the other company. For some reason or other, however, the Board of the other company changed their mind, and did not submit the agreement for confirmation to their shareholders at all. It is not for me to explain why they did not do so. It is possible that an explanation may be found in a change of policy which they have since adopted, which has consisted in the issue of a large number of new shares, and, with the funds so provided, to undertake in the first place the purchase of the business of the Platino Company, and now that of this Company. In the circular we issued in 1885, we pointed out to the shareholders that our shares were not negotiable on the Stock Exchange. Great inconvenience (the circular stated) had arisen in consequence of shareholders wishing to dispose of their shares, and suggestions had been made by large proprietors that the Company should be either reconstituted or merged in one or other of the larger telegraph companies of which it formed a portion. We further explained that a dispute existed between the Platino Company and the Western and Brazilian Company as to the right of one of those companies to participate in a portion of the earnings of the other company, that in that respect our interests were mixed up, and that had a suit come on we should have been parties to it; also that various subjects of friction had arisen which made it desirable that we should amalgamate. The terms offered to us in 1885 were that we should receive one share of the Western and Brazilian Company for three shares in our Company. They, on the other hand, were to bear all the expenses of the liquidation, the expenses of compensation for abolition of office, and they were also to pay off our Debenture debt. I think we have every cause to congratulate ourselves upon the agreement of 1885 not being carried out. It approved itself, however, to our shareholders. I do not think we had a single objection to it, and had it been carried out by the Western and Brazilian Company they would have acquired us on considerably better terms than those now under consideration. It is extremely satisfactory to me to know from the proxies that the shareholders' approval has been so general, because in the circular which we issued inviting those proxies we were obliged to put the case in its very mildest form. That circular was issued before the agreement had been ratified by the shareholders of the Western and Brazilian Company, and we were afraid that if we boasted of having made anything like a good bargain some of the shareholders in that company might object to the proposal, and that difficulties might be thrown in the way of carrying out the agreement. The Western and Brazilian Company have now confirmed the agreement at a meeting of their shareholders, and one may therefore explain to our shareholders exactly what the thing means. Putting the two offers on the same basis, by allowing for the liquidation of the mortgages, payment for compensation, and all those things, and simply taking the matter as regards the shareholders, under the offer of 1885 our Company would have received 2,972 shares in the Western and Brazilian Company, or one for every three of our shares, and the shares of the Western and Brazilian Company at that time were worth about £6 each. That is the figure at which we quoted them in our circular to the shareholders. In other words, there would have been available for distribution among our shareholders a sum of £17,832. Under the present offer we are to receive one share in the Western and Brazilian Company for every two of ours. In other words, excluding what is necessary for paying off the Debentures, compensation, &c., we are to receive for distribution among our shareholders 4,457 Western and Brazilian Shares, which are quoted at between 10 and 11, but say, for safety, 10. In other words, they have a value of £44,570 against the £17,832 of the 1885 offer.

A SHAREHOLDER: How much of our Debentures have been paid off?

The CHAIRMAN: I will come to that, but let me make my statement in my own way. In other words, the increase in the market value of the consideration we are now to receive, as compared with what we were willing to receive in 1885, is £26,738; and when you remember that the total amount divisible by the 1885 offer would have been £18,000, an increase of £26,000 on that amount may, I think, be termed a very fair bargain, and one showing sufficient interest in the concerns of the shareholders by those who were carrying it out. A gentleman has called my attention to the fact that, as we have mentioned in our own circular, our Company is in a better position now than it was in 1885, and I want to put the matter in the fairest light to our shareholders. Our Company has advanced in value, and we have paid better dividends by a long way latterly. But why has our Company advanced? Simply because the Western and Brazilian Company has advanced. Our earnings simply consist of a certain fixed percentage of the Western and Brazilian Company's earnings from a certain portion of their system, and any increased value of our Company—any increased dividend we have been able to pay—has simply arisen through the increased earnings of the Western and Brazilian Company, in whose shares we are to be paid. The increase in the value of our Company, however, has not been so great as in the case of the Western and Brazilian Company, because we do not participate in all the earnings of that company. They have a considerable revenue from land lines. I am now talking of the Western and Brazilian and the Platino Companies together, for they are now practically amalgamated. They have considerable earnings from land lines, in which we do not participate, and they derive advantages in rebates from other companies from which we do not benefit. Therefore, though it is clear that our Company must increase with the increase in value of the Western and Brazilian Company, yet our improvement is not to the same extent as theirs. The Western and Brazilian Company has increased in value more than we have, but for the sake of comparison we put that point out of the question. Assuming that we had increased in value to exactly the same extent as the Western and Brazilian Company, what do we find? When the shares of the Western and Brazilian Company were offered to us in 1885 they stood at £6 in the market, and they now stand at £10. Assuming our shares to have increased proportionately in value, and to have been worth what we were willing to accept for them in 1885—£2—they would now, by rule of three, be worth £3. 6s. 8d., but we are going to get £5 for them, or £1. 13s. 4d. a share for something not in any way connected with the increased revenue of our Company. What is that for? Our diminished indebtedness! We can measure the diminished indebtedness precisely. Our indebtedness has been since that date diminished by £5,380. Our diminished indebtedness between 1885, when we made our other arrangement with them, and the date at which we made our arrangement in 1890, amounts to £5,380, and in respect of that we are to have an increase of £1. 13s. 4d. per share, irrespective of any growth in value derivable from increased revenue. Well, £1. 13s. 4d. a share on our shares would amount to £14,850, showing a net increase in the price we received, beyond anything to justify it in the growth of value of our revenue or the diminution of our indebtedness, of £9,470, or close upon £10,000. I think that that shows we have made a very good bargain for the shareholders, and that their interests have not suffered through the agreement of 1885 not having been carried out. To put the matter still in another light—to show the advantages offered to the shareholders—the highest dividend we have ever been able to pay them has been 4s. 6d. per share. Half a share in the Western and Brazilian Company, which they will receive in exchange for their share, instead of paying 4s. 6d., will yield them a dividend of 6s. 9d. That I think ought to be satisfactory. It may be said that our revenue has increased. As I have told you before, our revenue can only increase through the increase in that of the Western and Brazilian Company, and if such an increase takes place you will benefit by it as shareholders in the Western and Brazilian Company. In addition to all this you will have shares which you can go on the market and sell, instead of being obliged to keep them in your safes as has been the case since you have been a Company. I do not think I have much more to say. I have mentioned the number of proxies in favour of our proposal, and we have only had, as far as I am aware, one shareholder who has intimated disapproval. That gentleman intimates his disapproval on two grounds. In the first place, under the agreement, we have intimated, in fact, to the shareholders that it would be necessary, and that we proposed to pay in dividing the assets of the Company, the Ordinary shareholders the same amount as we shall pay to the holders of the Preferred shares. Well, some of you may think that that is an inequitable mode of dealing with the assets of the Company; but we have no option in this matter. We are bound by the Articles of Association as to the way in which we should distribute the assets. The 4th Article reads thus: "The Preferred shareholders mentioned in the Memorandum of Association shall claim such preferential dividend as hereinafter mentioned, but in the distribution of assets

Digitized by Google

on a winding-up of the Company, they shall rank on an equal footing with the Ordinary shares mentioned in the Memorandum of Association." Now that I have read that, I think you will at once see that we have no power of making any other arrangement with regard to the Ordinary shares than that laid down in the Articles of Association. The second point on which exception has been taken by the one shareholder who has previously been hostile on the subject was the proposal in regard to the compensation of the Directors and officers of the Company. That is a delicate matter, and in considering it the Board felt constrained to take up what was an equitable and strong position. In 1885, in our negotiations with the Western and Brazilian Company, that company proposed to take upon itself the claim for compensation on the abolition of our offices. The secretary and myself had a long interview with the representative of the Board of the Western and Brazilian Company, at which the agreement was discussed. We had a great deal of wrangling about the terms that were offered to the shareholders. The interview lasted over several hours, and the interests of the shareholders at that meeting were, on our part, most vigorously fought and contested ; but with respect to the proposal for compensation upon the abolition of our offices, which was made by the Western and Brazilian Company, there was not one word of comment or dispute on our part. The Western and Brazilian Company made their offer, and it was accepted without one word of comment. That offer was embodied in the agreement which was approved at an extraordinary meeting of the shareholders in this Company, and we thought that on the present occasion we could not do better than propose to you the terms of compensation which had been offered by the Western and Brazilian Company when that company were going to pay them out of their own pockets. Those terms had been approved at the extraordinary general meeting of our shareholders in 1885, and they are the terms we are going to propose to you. It might fairly be argued, on the one hand, that as so much better terms have been obtained for the shareholders, better terms might be given to the officers ; but the remuneration of the officers is, of course, a fixed charge, and we never thought of making any such claim. I think if you are going to have compensation you could not have it fixed in a more impartial or sounder manner. It was fixed by the Western and Brazilian Company without the smallest haggling on our part when the Western and Brazilian Company was going to pay the compensation out of its own pocket. It might be said to us, "You are not entitled to any compensation at all," as some of our offices are only from year to year. So far as the Directors are concerned the question of compensation does not concern them much. Mr. Joicey is an original shareholder, and he and his friends hold over £30,000 in shares in the capital of the Company. I recently persuaded him to come upon this Board, but it was only under the threat that if he would not come and attend to his own interests I should not continue to do so for him. You cannot conceive that a man having £30,000 interest in a capital would care to spoil any bargain by what compensation he might receive out of a petty office like this. I have now to come to the secretary of the Company. After the last agreement was not carried out it became necessary for us if we were to conduct the negotiations with the Western and Brazilian Company to do so in a more or less reserved manner. A certain offer had been made to us by that company, subject to ratification by their shareholders. They had not had it ratified by their shareholders, however, and if we had gone running after them it would have appeared as if we were very anxious to get rid of our Company on any terms. The secretary acted as a sort of plenipotentiary in the matter. I do not know what the experience of others may be in other cases, but I venture to say that Mr. Fraser will do what is right, and will act for the benefit of his employers without regard to his own interests. I do not, however, think it would be encouraging to a man to say to him, "You go and negotiate and bring your own office to an end, and rest content with having done so, for we cannot consider the question of your compensation at all." I do not see how we could have left the point in that way. If we had done so we should, I believe, have been sacrificing the interests of the shareholders, for the merit of working out the whole details of this arrangement is due to Mr. Fraser. He brought us the information ; he was constantly in communication with the Board on the matter, but it was to his tact and pertinacity, I think, that we are indebted for the very great improvement in the terms we have obtained on the present occasion. I do not think that there is anything further to say except this, that under the law any member who disapproves of the agreement need not accept the shares. If the shareholder of whom I spoke as intimating, so far, his disapproval is present now, I hope that what I have said will partly explain matters to him, and will show him that his interest has been carefully guarded. It is proper that I should say a few words regarding the rights of a dissentient shareholder. The solicitors have, by the instructions of the Board, carefully looked into this matter, and have removed any doubt that might have existed in their minds, though I do not think they entertained any doubt. This is what they have written to us, "The sole right of a dissentient shareholder in such case is to require the liquidator to purchase his shares at a price to be fixed on by arbitration." I do not think that any shareholder would be likely to improve his position much by arbitration, and I do not think we need have to fear encountering any dissentient shareholders. I will, therefore, without further preface, propose the resolutions.

A SHAREHOLDER: Is there any objection to stating how you are to be compensated?

The CHAIRMAN replied in the negative, and pointed out that the terms were embodied in Resolution No. 5.

Mr. JOICEY, M.P., seconded the motion, observing that he was the largest shareholder in the Company. There was, he said, one point which the Chairman had omitted to refer to which he (Mr. Joicey) looked upon as rather a serious one—namely, the gradual disappearance, practically, of the property, as their concessions terminated in the course of about 22 years. He was a man who had had some experience in this matter, and he knew the difficulty there very often was in getting a concession renewed. While the Chairman had instituted a comparison with five years ago, they must not forget that their property was practically five years less value at the present time. He thought that the very fact that by a transference of this property to the Western Company they would get a marketable security ought to make them all very well satisfied with the proposed bargain.

Mr. NEILD inquired how long the Western and Brazilian Company's concessions had to run?

The CHAIRMAN replied that he could not state this information. In making the proposed arrangement they were considering the market value of the shares.

Mr. F. GORE BROWNE observed that the bargain appeared to him to be a very good one, and as representing some executors who had been anxious to get rid of their shares for a long time, he would not be disposed to submit to arbitration, and get his shares valued by an arbitrator whom he would confidently expect to give a lower value than he could obtain by accepting the Western Company's shares, and afterwards selling them in the market. It appeared that the Western Company paid this Company last year by way of rent or share of profits £3,783, and they now offered them practically £80,000 of nominal capital to buy this Company out. That £80,000 at 4½ per cent.—the rate of dividend which, he believed, the Western Company were now paying—gave £3,600. It was true that the Western Company thus made a small saving of £183 on the amount they would give to this Company ; but as a set-off against that, this Company would save their current working expenses. The arrangement seemed to him to be a reasonable bargain between the two parties, doing justice to both.

Mr. MACKINNON also supported the proposal.

The CHAIRMAN put the resolutions *en bloc*, and they were unanimously agreed to.

On the motion of Mr. F. GORE BROWNE a vote of thanks to the Chairman was passed, and the meeting then separated.

## The Swan United Electric Light Company (Limited).

The eighth ordinary general meeting of the shareholders was held at the Cannon-street Hotel on the 25th inst., under the presidency of J. S. Forbes, Esq.

The SECRETARY and MANAGER (Major S. Flood Page) read the notice convening the meeting.

The CHAIRMAN said: Gentlemen,—The report and accounts have been printed and circulated ; I suppose, therefore, I may take them as read. If that is your wish I will proceed to make the usual remarks upon them. I think, in view of the fact that we only meet you yearly, and that possibly in the course of the current year we have a good many fresh proprietors, I had better begin with the balance-sheet, and explain what the position of this Company really is, for to the uninitiated it is somewhat complicated. You will remember that its title is the Swan United Electric Light Company, and it is a union of two parts. The owners of the British patents and the owners of the foreign patents put them together and formed the Swan United Company, and in the course of time you will also remember that that union was dissolved. In fact, there was a sort of divorce because another competitor had cropped up—the Edison Company—and the position of the Swan United Company was so far altered that they made over their better half to the Edison, and retained for themselves their foreign connections. Now, with that little introduction, which I shall be able to apply as I go through the balance-sheet, you will ascertain really upon what basis your property rests to-day. If you will kindly follow the capital account you will see what the share capital of this Company is. It is so many partially paid shares, amounting in the aggregate to £375,071. Well, of these shares a number representing £3,530 had been taken up by people who omitted or declined to pay up their calls. Those shares were, therefore, forfeited, and, of course, to that extent are to the good of the Company. That is the barebones of that side of the account ; all the other items which follow have nothing to do with that essential part, the capital of the Company. You will see where it has got to. On the opposite side of the balance-sheet you will see "By cost of patent rights, &c.," represented by shares in Edison and Swan United Electric Light Company (Limited), £208,478, and the French Company, £30,489 ; and over and above these two solid assets, as typified by those figures, we have got patents held by the Company for Germany and other sources of income which are open to you as possessors of the patent either in England or abroad, outside Europe. Now comes the importance of this second operation—the absorption by the Edison and Swan Company of the British business of the Swan United. You will see that it stands at £208,478. You will find, when you come to deal with the dividends, what a very happy investment that has turned out so far as it goes at present. The bulk of the dividend which we propose to you to divide will have been derived from the interest coming to you in respect of those shares in the Edison and Swan Company. Well, with regard to the French Company, you know what we did there. We were in litigation with a powerful body of people in France, and France meant Russia, Austria, and some other countries ; and the Edison Company and the Swan Company were doing in France what we were about to do in London when, fortunately, the two concerns were fused. They were litigating in regard to the patents. We thought it was wise to avoid litigation as regards ourselves, and we came to terms, and a Company was formed of the Edison and Swan. Some amount of money was subscribed by the two companies, and they were each credited with a further amount of capital in respect of what was called the goodwill of the patents, our portion being £30,489, cash paid. Two million of francs is the nominal capital of the Company ; one million francs represented the sovereigns paid to carry on the business, and the other million of francs the goodwill and patents. Now, the other item of assets or property lies in

Digitized by Google

the unknown; the residuum, the German patents, with all they mean, and certain other rights which the Swan Company have got as the result of an agreement—the outcome of negotiations. For instance, they have a very large area out of Europe which they can supply with lamps if they can obtain customers. When I come to deal with the profit and loss account you will see how the capital is affected as regards your property and your income. Now, perhaps, I had better go through the items in the balance-sheet. It is apparently in its wrong place, because it contains items carried from the profit and loss account which should be dealt with, in fact, before the balance-sheet. The first item is sundry creditors, £3,477. On the opposite side the sundry debtors amount to £26,733. It seems a good deal of money to be owing, but the bulk of that is represented by the dividend payable by the Edison and Swan Company to ourselves—£25,000 out of the £26,000. Therefore the sundry debtors and sundry creditors about balance themselves. Then there is a balance from the previous account. The older shareholders, at any rate, will remember that for some years we paid no dividend, and, what is a great deal worse, for some years the balance at the end of the year was against the undertaking. There were losses instead of gains, and we determined to do, as a matter of prudence, what probably the law would insist upon our doing if the point was raised, namely, to write down out of the profits of the following years all losses suffered in the earlier years of the Company. The first time we had a balance to the good was on September 30, 1887, when £1,720 was brought in, and in the following year, 1838, we had a further credit balance of £8,332. The proprietors fully concurred with the Directors in recommending that both those amounts should be held in hand. We had litigation pending in Germany, with possible damages, and we thought it better to build up the credit of the concern by storing the earlier gains until our Company was more fully developed. In 1889 our profit had increased to £21,011, and, as you will remember, for the first time in the history of the Company, in 1889 we distributed a dividend. In the balance-sheet this balance from previous accounts amounts to £31,094, less dividends paid November 20, 1889, £22,203, which, you see, leaves £8,886 to be carried forward. Now, where the profit and loss comes in you will find balance Sepember 30, 1890, £35,590, and if you will cast your eye down the profit and loss account on the debtor side, and add this balance for the year to £8,806, you will see that the unexhausted profits up to September, 1890, come to £44,477, less the interim dividend at the rate of 6 per cent. per annum paid on May 21, 1890—£11,104, leaving £33,373 to be disposed of. The item of stock, which, of course, is an asset of the Company, and which amounts to £11,124, represents a very great number of manufactured lamps; and the value in the shape of platinum, bulbs, and material is entered here at a figure very much below selling value. We have thought it prudent in this account from time to time to put down the stock carried forward at approximately the manufactured price, leaving the question of profit, although it is pretty secure as a deferred stake, because it is possible that something may arise—though it is hardly within the bounds of probability—to prevent the sale of this stock of lamps at a value exceeding its manufactured price. Well, now, if any gentlemen would like to inquire into the substantial asset of the Company they will see what it is by the figures given with respect to the Edison and Swan and the French Companies, and they will also see the other items of capital investments in Consols, stock, cash in hand, and so forth. By turning to the profit and loss account you will see what the items of stock are. The purchases, as you will notice, are £9,115. That means partly materials and partly lamps. I may mention that we had from time to time the advantage of working in amity with the Edison and Swan Company. As we were united with them in our mutual interests we were able to play into each other's hands, and it happened that a demand set in for lamps in Germany which they could not supply. Fortunately, we were able to supply these lamps for them, and this item embraces the lamps so purchased and the material used up in the factory at Kalk, near Cologne, where, over and above the lamps so supplied, are manufactured a considerable number. The next item is office expenses, Directors' fees, rent, salaries, income-tax, &c., £3,513; wages and expenses at factory, £5,046. That is, wages and expenses as distinct from material or lamps. Depreciation, the item already referred to, is £490. Sales—ledger reserve—£150. This is in case we make bad debts. We have no anticipation of doing so, only we like to be on the right side. On the other side of the account there is the item by sales, less commissions and allowances, £12,317, and also the item of transfer fees and interest, £1,763. Now, these two items are realised from what may be called the open asset of the Swan Company—the power to make lamps in Germany, or to make or license somebody else to make and export lamps; and the interest on investments—£5,000 in Prussian Consols, and £29,000, in round numbers, in English New Two and Three-quarter per Cent. Consols. Then we come to the income depending upon the fixed investments, namely, the dividend on shares in La Compagnie Générale, £1,771; and dividends on shares in the Edison and Swan United Electric Light Company, £30,655, which is a big figure. In fact, this sum comes to 8 per cent. upon the whole of your capital. That is a very important thing, and I dare say those gentlemen who have taken sufficient interest in the affairs of the Edison and Swan Company to attend their meetings or read their reports will know, humanly speaking, that the future of that Company is likely to be fairly prosperous. We have, as you know, got protection for a certain number of years, but our policy has not been founded upon protection at all. It is founded upon, at the end of the protected period, having such a character and *clientèle* and capacity for production that nobody else can have any chance of competing with us. Well, we must work to that standard. As long as the protecting period lasts there is no doubt that the dividend upon the Edison and Swan Company may be looked for as a tolerable one. Well, now, the French Company, although they have only started very recently have a fine factory, but they have not succeeded in doing as well as we do in the production of lamps. First of all, they do not make nearly so many as we do, and, of course, it takes a certain time to develop a very efficient and at the same time a very economical lamp. The processes are so very multifarious and technical that it requires considerable practice to get into the best groove. Of course, there is the advantage of their having the Edison and Swan interested more or less in them as partners, and we are enabled to give them the benefit of our large experience at our great works at Ponder's End, where, of course, we have had from the beginning the advice of the best technical men, including Mr. Swan, than whom there is no greater authority. At Ponder's End we have succeeded in producing lamps of an efficient kind at moderate prices, and our French friends have had the benefit of our experience. They paid 6 per cent. to the end of December, their year ending later than ours. We ought to have had some dividend in respect of the period succeeding that, but we have thought it prudent not to put it into the account until we have got it. France is still engaged in litigation about the patents, because there are in France, as in other places, a great number of people who like to avail themselves of the fruit of other people's brains without paying for it, and so in France there are plenty of infringers. We blame the lawyers in England, and the law's delay is a household word among us; but our experience of Germany in this respect is only capped by our experience of France as to the difficulty of getting the law to settle anything. The proceedings are going on there, and are likely to go on, and until the litigation is finished we do not know the value of our business. I think I have now about exhausted the balance-sheet and the profit and loss account, and the report as well, as it only contains in other words what I have been telling you. The credit balance of £44,477 is brought out in paragraph two. That sum you will find in the balance-sheet is diminished by the interim dividend, already paid, by £11,104. We propose to pay a dividend at the rate of 10 per cent. for the entire year, and to carry forward £8,451, which is very nearly the amount of the accumulated undivided profits which was brought into the year's accounts, and, therefore, the payment of 10 per cent. means the distribution, as nearly as possible, of the year's profits. The decision in the patent suit in Germany was given in favour of this Company in the Court of Appeal, in Berlin, during the summer. We were beaten in the first Court, although the Patent Department in Germany, after being consulted on the matter, gave a report in our favour. But the judge did not take quite the same view of the matter, and we had to appeal, and in that appeal we succeeded in obtaining a decision that the Swan Patent is not an infringement of the Edison, we were decreed by the Court of Appeal not to be infringing it. Of course, if we did it would be rather a serious matter. We should then have either to make terms with the Edison Company or shut up shop; but we are going to continue making the lamps, and selling them, and also realise a profit on them, until the decision of the Supreme Court at Leipsic is given. Only then shall we know if we shall be able to go on making our lamps in Germany or not. In Paris they are contesting the validity of the French patents, and we hope to get a decision there next spring. Meanwhile, they are going on making the lamps and selling them. Whilst these judicial proceedings in France and Germany are pending, everybody in these countries are making lamps, and selling them, with the result that the price is affected. Under the circumstances the companies in these countries have to bear the burden of defending their suits, and at the same time to lower their price for the lamps in order to keep pace for the time being with the infringers. What has happened here may happen there, namely, when we got hold of notorious infringers they had, at the end of the litigation, to reimburse us a good solid sum for the lamps that they had sold. I have no subject for further comment, unless any question shall elicit anything fresh; and I will now move,

"*That the report and accounts for the year ending September 30, 1890, be received and adopted.*"

Mr. F. R. LEYLAND seconded the motion.

In reply to questions and remarks of Mr. Mills, the CHAIRMAN stated that the dividend payable this year had, of course, been earned in the current year by the Edison and Swan Company, which would hardly pay a dividend unless it had been earned. Certain shareholders, of whom their own Company was the largest, were entitled out of the profits of each year to a dividend of 7 per cent. before the Deferred shareholders received anything; and this 7 per cent. was cumulative. For a number of years no dividend was paid to the Edison and Swan shareholders, and for a number of years it was only partly paid. Against those years were booked up the future profits over the heads of the Deferred shareholders. The amount was still very large, he believed considerably over £100,000, and that had to come back out of the profits of each year over and above the 7 per cent. referred to. When this incumbrance was paid off, the Deferred shareholders would participate in the profits over 7 per cent. to the extent of one-fourth. There was, it was true, a large amount of stock carried forward compared with the amount of stock brought forward: but they had increased the manufacture not in reference merely to the year, but with some forecast for the future. However, they had already sold about one-half the number of lamps embraced in the item in question at a price pretty nearly representing the whole amount at which the stock was valued in the books. He could not agree that the office expenses, £3,513, were too high. Of this amount the Board received £1,500, and their services were very cheap at that price (hear, hear, and laughter). They had very great interests to safeguard. As to their having too much money in hand, they could not return any of it to the shareholders merely of their own free will. They would have to reduce the amount of the capital of the Company, and to go to the Court of Chancery and all that sort of thing. Moreover, he did not believe they would have any too much money, in view of the development of their business in Germany, should they succeed in the litigation in establishing their

Digitized by Google

contention. At present they were working in that country with a very small capital, having thought it more prudent and wiser in every respect, in the existing uncertainty, to retain the money in Consols, rather than expend it in establishing large works in Germany. The patents would expire in between three and four years. There was not the least chance that they would be renewed, and honestly he believed that they would be a great deal better without them. Hitherto the electric light had only been "creeping along," but there were evidences now that it was making enormous progress, and their lamp was the key of the position.

The motion was then unanimously adopted.

The CHAIRMAN next proposed the following resolution :—

"*That in addition to the interim dividend at the rate of 6 per cent. per annum for the six months ended March 31, 1890, already distributed, a dividend at the rate of 6 per cent. per annum be, and is hereby declared on the shares of the Company for the half-year ended September 30, 1890 (making 6 per cent. for the year), and of 4 per cent. for the 12 months ended September 30, 1890, free of income-tax ; to be distributed in accordance with the provisions of Clause 77 of the Articles of Association.*"

Mr. LEYLAND seconded the motion, which was carried unanimously.

Resolutions were afterwards unanimously passed re-electing the retiring Directors—Mr. F. R. Leyland and Mr. Quilter, M.P., and the auditors, Messrs. Welton, Jones, and Co.

Mr. H. H. DOBREE then proposed a hearty vote of thanks to the Chairman and Directors.

Mr. MILLS, in seconding the motion (which was carried unanimously), said he had not had the least intention in his previous remarks of criticising the Directors' remuneration.

The CHAIRMAN, in reply, stated that whenever the litigation in Germany was closed, the necessity for keeping the Edison and Swan Company and the Swan Company as two separate undertakings would cease, both these heads would be put under the same umbrella, and this would materially reduce the expenses.

The proceedings then closed.

---

## Reuter's Telegraph Company (Limited).

Notice is given that a special meeting of this Company will be held at 24, Old Jewry, on Saturday, December 6th, at 12 o'clock noon, when the subjoined resolutions will be proposed and submitted to the Company :—

"1. That the capital of the Company be increased to £100,000 by the creation of 2,500 new shares of £8 each, and that the Directors be forthwith authorised, under the provisions of clause 26 of the Articles of Association of the Company, to issue such shares.

"2. That, subject to the provisions of the Company's (Memorandum of Association) Act, 1890, the provisions of the Memorandum of Association of the Company, with respect to the objects of the Company, may be altered as follows, that is to say, by expunging sub-sections 2 and 3 of clause 3 of the Memorandum of Association, and by inserting in lieu of the sub-sections so expunged the following sections :—

"(2) To carry on and extend the said business and generally to carry on, acquire, obtain, and supply telegraphic, telephonic, or other news and intelligence, and to issue, publish, and circulate, and otherwise utilise, with a view to the profit or advantage of the Company, the same news and intelligence.

"(3) To carry on in the United Kingdom, and in any part of the world, the business of general advertisement contractors and advertising agents in all its branches.

"(3A) To construct, purchase, hire, or otherwise acquire, or work telegraphs and telephones for any of the purposes hereinbefore mentioned."

## Electric Construction Corporation (Limited).

The following is the report of the Directors to be submitted to the shareholders at the ordinary general meeting to be held at Worcester House, Walbrook, London, E.C., on Monday, December 8, 1890, at twelve o'clock noon :—

The Directors beg to submit the accounts of the Corporation up to September 30, 1890, showing a profit of £52,639. 3s. 2d. This may be considered as eminently satisfactory, having regard to the facts that (1) the Corporation did not enter into full possession of all the properties acquired until October 31, 1889 ; and (2) the Corporation has not during the past year had the benefit of the increased power and economy of production to be derived from the new Bushbury Works, to which special reference is hereafter made.

*Profit and Loss Account.*—From the profit of £52,639 3s. 2d., the Board have written off the whole of the preliminary expenses of the formation of the Corporation, amounting to £4,348 7s. 6d., and they have also carried to capital account a considerable sum resulting from licenses and resales of patents. No patents have been sold or licences granted which can, in the opinion of the Directors, prejudice the profit earning power of the Corporation, and possibly a certain portion of the amount so applied to capital might have been regarded as divisible profits ; but, having regard to the large amount of the capital of the Corporation at present represented by patent rights, the Directors are satisfied that the shareholders will support the more prudent policy which has been adopted.

*Application of Profits.*—From the profit balance of £48,290. 15s. 8d. the Directors recommend :—(1) That the sum of £15,000 be placed to reserve account against depreciation ; (2) That a dividend of 6 per cent. be declared and paid upon the capital which has been from time to time called up, and paid in respect of the ordinary shares of the Corporation, from the date of allotment on June 7, 1889, to September 30, 1890, inclusive, carrying forward the balance to the current year's account.

*Bushbury New Works.*—At an early date after acquisition of the Elwell-Parker business, the Directors satisfied themselves that the existing Wolverhampton (Commercial-road) Works were inadequate to cope with the large and increasing orders for electrical goods, and particularly for those of the heavier class now in demand for central stations. A very advantageous site was secured at Bushbury, near Wolverhampton, immediately adjoining and in direct communication with the London and North-Western Railway Company. Works have been there erected which, it is believed, will enable the Corporation to supply electrical work of any class ; but, having regard to the manner in which the business of the Corporation has developed, provision has been made for still further extensions should the necessity arise. The cost of the construction of these works, with the necessary land, sidings, and machinery, has, of necessity, been great ; but the Directors are satisfied that the capital of the Corporation has been well expended.

*Increase of Capital.*—In the prospectus of the Corporation it was stated that "as the business and profits of the Corporation increase, the Directors will from time to time propose the issue of additional capital, but care will be taken that the holders of the original capital shall be entitled to a preference or priority of allotment in subsequent issues." To secure the full advantage and profits of increasing business it is desirable that a considerable addition should be made to the resources of the Corporation. In the opinion of the Directors a Debenture issue would be more economical and advantageous to the present shareholders than an increase of capital either by ordinary or preference shares. Subject to any expression of opinion on the part of the shareholders at the general meeting, the

Directors therefore propose to make a sufficient debenture issue. Care will be taken that shareholders desiring to subscribe to these debentures shall have the opportunity of doing so.

*Directors.*—In accordance with the Articles of Association, four of the Directors, viz.: Sir Daniel Cooper, with Messrs. Balfour, Courtenay and Dibley, retire from the Board, all of whom are eligible, and offer themselves for re-election. The Directors regret that the pressure of his professional engagements has compelled Sir Douglas Fox to resign his seat at the Board. Sir Henry C. Mance, C.I.E., has consented to give the Corporation the benefit of his great experience and scientific knowledge as Chairman of the Board.

*Auditors.*—Messrs. Broads, Paterson, and Co., the present Auditors of the Corporation, retire, and offer themselves for re-election.

## Blackpool Electric Tramway Company (Limited).

The annual meeting of the shareholders of this Company was held on Saturday last at Blackpool, the Chairman of the Company, Mr. Alderman Richard Horsfall, J.P., being in the chair.

In moving the adoption of the report (given below), Mr. HORSFALL said it was his pleasure to meet them again as Chairman of the Company, and congratulate them upon their balance-sheet. He did not know that he had anything to say except that they were working satisfactorily and that all their machinery was in good working order. The finances were good, and the Directors felt they came before them with a thorough, sound, and honest balance-sheet. He had great pleasure in moving the adoption of the report and balance-sheet, which allowed a dividend of 7½ per cent.

Mr. T. H. MORRIS, J.P., Halifax, seconded. He thought the Directors had much satisfaction in confirming what had been said. Their plant was in good order, and their prospects were never more satisfactory than they were at the present moment. The dividend had been honestly and satisfactorily earned, and the depreciation put by (£1,000) was only for the contingencies of the Company at a future date.

The report having been unanimously adopted, and the retiring Directors and auditor having been re-elected, the CHAIRMAN, in responding to a vote of thanks to the Directors and officers, said he was not of opinion that the Corporation would take over the concern at the end of the first seven years' term, which expires next year.

The following is the Directors' report:—"The revenue account shows a balance in hand for the year of £2,455. 9s. 3d. Adding to this £231. 5s. 10½d. from last year makes an available amount of £2,686. 15s. 1½d., of which the Directors recommend the following disposal: Dividend of 7½ per cent. on the called-up share capital, free of tax, £1,501. 17s. 6d.; depreciation and reserve fund, £1,000; balance to next year's account, £184. 17s. 7½d. The depreciation and reserve fund, with the addition of £1,000 as above recommended, will be £4,418. 15s. 1d. The number of passengers carried this year was 812,299. The number of miles run during the year was about 92,000. The retiring Directors are Messrs. Ormerod, Shaw, and Smith, who are eligible for re-election. Mr. Broadbent's services as Managing Director have been secured again for the coming year."

## NEW COMPANIES REGISTERED.

**ANGLO-MEXICAN SAW-MILLS COMPANY (LIMITED).**—Registered by Mr. James Curtis, 1, Old Jewry-chambers, E.C., with a capital of £5,000 in £1 shares. Objects: To carry on in Mexico the business of saw-mill proprietors, and to acquire all necessary rights of using steam, electricity, or water power in connection therewith; and to acquire and deal with patent machinery, apparatus, and materials for the production and distribution of electricity.

**CHAGFORD AND DEVON ELECTRIC LIGHT COMPANY (LIMITED).**—This Company was registered on the 18th inst., with a capital of £2,000, in £1 shares, to adopt an agreement of 12th inst., with Edmund Eaton and G. H. Read, for supplying electric light to Chagford, Devonshire. Registered without special articles by Mr. J. Fleming, 27, Martin's-lane.

**"ELECTRICITY AND ELECTRICAL ENGINEERING" NEWSPAPER COMPANY (LIMITED).**—This company was registered on the 18th inst., with a capital of £500, in £10 shares, to establish and work a newspaper in the interest of electrical science in all branches. The subscribers are:—Wm. Swan Sonnenschein, 62, Russell-square, publisher; H. Wigham, Uplands, East Sheen, publisher; R. O. Smith, 73, Eaton-square, publisher; F. C. Tilney, 126, Corbyn-street, N., clerk; Julius Maier, Ph.D., 23, Melrose-gardens, W.; F. D. Summers, 13, Oberstein-road, Wandsworth, private secretary; G. Newnes, M.P., Wildcroft, Putney-heath. Registered without Special Articles. Solicitors, Messrs. Bowman and Co., 21, Bedford-row.

**ERNEST SCOTT AND MOUNTAIN (LIMITED).**—Registered by Slaughter and May, 21, Great Winchester-street, E.C., with a capital of £70,000, in £10 shares. Object: To carry into effect (1) an agreement, made October 11th, between Ernest Scott, trading as Ernest Scott and Co., and E. H. Turner; (2) an agreement of the same date, made between E. H. Turner and Ernest Scott; (3) an agreement of the same date, made between E. H. Turner and William C. Mountain; to carry on the business of electrical and general engineers, machine and engineering tool makers, &c. There shall not be less than three nor more than five Directors. The first to be appointed by the subscribers to the Memorandum of Association. Qualification, £1,000. Remuneration, £200 each.

**ELECTROLYTIC SYNDICATE (LIMITED).**—Registered by the Metropolitan and Provincial Syndicate (Limited), Lonsdale Chambers, 27, Chancery-lane, with a capital of £100,000 in £1 shares. Object, to carry into effect the following agreements:—(1) An agreement made October 25th between William Elmore and Alfred Wells; (2) an agreement made October 24th between Arthur Cooper and Alfred Wells; (3) an agreement made October 25th between John Fraser and Alfred Wells; (4) an agreement made October 23rd between Woodhouse and Rawson United (Limited) of the first part, William Elmore, Frank Elmore, and A. S. Elmore of the second part, and Alfred Wells of the third part; to carry on as principals or agents business as miners, metallurgists, and smelters. The first subscribers are:—J. J. Atkinson, Cosgrove Priory, Northants; W. Elmore, 47, Clapham-road, S.W.; J. T. Cooper, Cregg, Nightingale-lane, S.W.; F. Safford, 2, Garden-court, Temple; S. Evans, Lonsdale Chambers, Chancery-lane; W. J. Tipputt, 11, Maiden-lane, E.C.; W. J. Peck, Redcar House, Redcar. Registered without Articles of Association.

**FINANCIAL EXCHANGE AND BUREAU (LIMITED).**—Registered by Robertson and Farmer, 8, Leadenhall-street, E.C., with a capital of £10,000, in 99 ordinary shares of £100, and 50 Founders' shares of £2 each. Objects: To carry on business as principals or agents for, and in the sale, purchase, negotiation, or dealing with industrial concerns, railways, loans, concessions, gas, water, electric, and all other works.

**SOUTH MOLTON SHIRT AND COLLAR MANUFACTURING COMPANY (LIMITED).**—This Company was registered on the 7th inst., with a capital of £5,000, in £10 shares, to manufacture shirts, collars, and cuffs, and to supply electricity for lighting and other purposes! Solicitors, Messrs Riccard and Son, South Molton, Devon.

## CITY NOTES, &c.

**BRAZILIAN SUBMARINE TELEGRAPH COMPANY.**—The receipts of this Company for the week ended November 21st amounted to £5,637.

**STOCK EXCHANGE.**—The Committee have appointed Tuesday, December 2nd, a special settling day in Elmore's French Patent Copper Depositing Company (Limited)—shares Nos. 1 to 66,750.

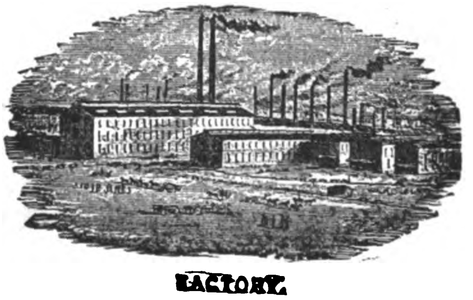
**WESTERN AND BRAZILIAN TELEGRAPH COMPANY.**—The traffic receipts of this Company for the week ending November 21, 1890, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited) were £4,421.

THE NON-CONDUCTOR OF ELECTRICITY.

**VULCANISED FIBRE,**
PATENTED.

This new material is supplied in two qualities, Flexible and Hard.
The FLEXIBLE is a substitute for Leather, Rubber, Gutta Percha, &c., and is extensively used by Brass Founders, Axle Makers, Hydraulic, Sanitary, and other Engineers, Pump Makers, Carriage Builders, &c.
It makes the best Hot and Cold Water Packings, and for Axle Washers of all kinds it is unequalled.
The HARD is a substitute for Metals, Hard Wood, Ivory, Vulcanite, Ebonite, &c., and is a good Insulator.
Sold in sheets, 5ft. 6in. by 2ft. 6in., varying in thickness from 1-50in. to 1in.

FLEXIBLE, 2/- per lb.; HARD, 2/8 per lb.



FACTORY.

# THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 655.—Vol. XXVI. FRIDAY, DECEMBER 5, 1890. Price Fourpence.

## NOTES.

The election of Sir William Thomson to the Presidency of the Royal Society is an event of so much interest to the electrical world, that its premature disclosure at the Institution of Electrical Engineers' dinner was a thing to be expected, and not to be blamed. Sir William is the foremost representative of the electrical, and indeed, of physical science of his time. His elevation is well timed in every respect, and will serve as much as anything else to lend interest and prestige to a subject which deserves all the attention it can command just now, both from the public and from the scientific world.

It is difficult to express the disappointment and regret with which we learn that the mischief caused by the fire at the Grosvenor Gallery has not yet ceased. A set of transformers was arranged with fire-proof precautions, and nearly all the circuits were running on Wednesday, November 26th. The transformers were not those which are destined to distribute the current from Deptford to the supply circuits, but were a number temporarily banked together, some being new and others being some of those which had survived the fire, and which had been repaired as thoroughly as possible. On Tuesday last one of these hastily repaired transformers became overloaded and burned out; the load was thus transferred to the others, which "went," one after the other, in the manner familiar to those who have attempted to run glow lamps on an arc circuit. It is expected that one circuit will be resumed to-day. We have not sufficient information as to the magnitude of the damage as compared with that which was produced directly by the fire, and it is only a small comfort to know that the disaster was due neither to the high pressure, the Ferranti mains, or to any other peculiar feature of this bold but unlucky concern.

The discussion on the Accumulator Papers at the Institution of Electrical Engineers on Thursday last, although productive of some important remarks, was not very satisfactory from a practical point of view. It could not be expected to be very fruitful in this respect, since those who were most qualified to speak with authority were also those most restricted from doing so by commercial considerations. Several specimens of grids and plates were exhibited in illustration of recent improvements in manufacture, and also to show the great durability of accumulator plates if only proper care is taken. Mr. Drake's remarks about the use of dense acid (S.G. = 1·350) were especially interesting, because if cells containing such acid have remained in good condition for over six years it becomes an important question whether any increase of efficiency would result from using acid of other than the normal density.

The question of acid density seems a very important one from the theoretical point of view. Mr. Hibbert considers that the changes in the voltage of the cell are mainly due to alterations in the density of the acid at the surfaces of the plates. The chemical actions going on within the cell are very complex, and have not been rendered any clearer by the discussion at the Institution, or at that which took place the following day at the Physical Society in connection with a paper on accumulators by Gladstone and Hibbert. Electrical Engineers cannot enter deeply into the theoretical reasons for and against the views of Dr. Frankland as to the formation of complex sub-sulphates during the charge and discharge. They will be inclined to follow Dr. Gladstone in his belief that there is no conclusive chemical evidence for the existence of such compounds. According to Gladstone and Hibbert, the percentage of lead to sulphate actually found agreed much more nearly with the ordinary substance $PbSO_4$ than with the subsulphate of Dr. Frankland; and this view was confirmed by Mr. Robertson, who undertook the chemical analyses referred to in the Paper by Prof. Ayrton. The simple theory, however, cannot explain the rapid alteration in volts at some parts of the charge and discharge, nor does it account satisfactorily for the fact that cells may be left with safety only when fully charged.

One of the most satisfactory features of the paper, and of the discussion which took place on the first evening, was the simplicity of the chemistry of the subject. It is well known that many electrical engineers have held aloof from the investigations of secondary batteries, not only on account of the complexities of the chemical actions, but because chemists cannot agree amongst themselves as to the changes which take place, or as to the constitution of either plate at any given moment. The hopes which were raised in the minds of many, that the time had now come when the chemistry may be stated in a simple manner, are sadly disappointed, and we are threatened with mysterious sub-sulphates, into the consideration of which the majority of engineers have neither time nor inclination to enter. It is apparent to all who have had to do with accumulators in practice that it is no more necessary to

Digitized by Google

deal with the notion of $S_2Pb_3O_{10}$ either in the construction or in the use of a battery, than to use quaternions in designing or running a dynamo. It is to be hoped that the chemists will clear this matter up shortly, or electrical engineers will be driven to take refuge in some provisional hypothesis from which it will be difficult to drive them.

THE Paper by Mr. WEBSTER on the electrical treatment of sewage suffered from the absence of actual figures relating both to the treatment and cost, owing to a delay in the publication of the official report on the experiments at Salford, and it was placed at an additional disadvantage owing to the absence of the author through ill-health. While the question is one of literally vital importance to this country, the question of cost must remain as the leading factor in any comparison with other systems. The figures given by the author need some further explanation. It is not clear how 400 indicated horse-power can be generated, continuously we presume, for £2,500 per annum. Taking the volts at 1·8, this 400 horse-power for ten million gallons corresponds fairly well with ·37 ampere-hour per gallon, and is equivalent to 6,600 kilowatt-hours a day. At three half-pence per kilowatt this amounts to about £41 per day. One penny per horse-power hour, as suggested in the discussion, comes to £40 per day, or £14,600 per annum. It is very remarkable that if an attempt be made to imitate an electrolytic action by chemical decomposition, the action is not so great. It has been shown that a certain quantity of chlorine given off by the decomposition of common salt by an acid is not so efficient as the same quantity produced by electrolysis. Similarly, attempts have been made to treat sewage by the salts of iron which Mr. Webster's process produces, but the results are not so good.

THE pretty experiment shown by Prof. SILVANUS THOMPSON to the Physical Society, on Friday last, in illustration of Prof. EWING'S theory of magnetism is important in view of future magnetic researches, as well as in connection with mere lecture purposes. Now it is known that small encased magnetic needles can be easily procured in quantities at a reasonable cost we may expect that the behaviour of groups of such magnetic elements, under the influence of magnetic force, may become the subject of experimental study. The mathematical investigation of such actions is quite hopeless, as it would involve the calculus of probabilities, and life is as a rule too short. Experiments on the influence of different groupings of needles can, however, very quickly be made. Prof. THOMPSON has, indeed, already succeeded in using the method to explain the fact, first observed by himself, that the two forms in which magnetite exists exhibit different powers of retentiveness for magnetism. The simple explanation is that the homogeneous variety acts like a number of magnetic needles far apart compared with their length, while the heterogeneous specimens act as if the magnetic elements composing them were close together.

INFORMATION on the life and efficiency of glow lamps is becoming a matter of considerable importance now that the manufacture of cheap lamps has assumed so important dimensions. We alluded to this subject only three weeks ago in connection with the reduced price of lamps in the United States. We publish this week an abstract of a paper by Professor NICHOLS, which clearly describes some of the imperfections to which glow lamps are liable, and which may be expected to assume very serious proportions when lamps are made for sixpence and sold for a shilling as may be expected two or three years hence. The defects are well known, but at present their magnitude is not a matter of great importance, partly because we have no choice, and partly because we believe that the one make of lamp which is for sale is a good one, if the eight-candle hundred-volt lamp be excepted.

THE second part of Professor NICHOLS' paper relating to that radiation which Professor E. WIEDEMANN has called "Luminescence," is of great interest both to the physicist and to the lamp maker. The connection between the dazzling brilliance of the flame of burning magnesium and the radiating power of the oxide of that metal in an as it were passive state, is not at first sight apparent. It appears that we have hitherto been too prone to follow the theory of exchanges in considering the emissivity of incandescent solids; at the same time it must be remembered that not one of the numberless inventions of refractory materials for mixing with or for superseding carbon, have yet proved to be of any real value.

OUR friends across the Channel have always been noted for the degree to which they place patriotism before pocket, and one result of carrying this highly commendable principle to excess is to be seen, we think, in the *projet de taxation*, which will be found in another column. The French electrical industry, already considerably cockered in one way and another, is, if we are to believe the statements of its representatives, in a very parlous condition; a high "compensatory" import tariff being absolutely essential to its continued existence. Doctors sometimes recommend a judicious course of "roughing it" to delicate indivduals, and we are inclined to think that something analogous would benefit the French electrical industry almost as much, and the unfortunate consumer considerably more, than a hot-house *projet de taxation*.

THE voltmeter of Mr. WESTON, of the permanent magnet type, is, we believe, as excellent in its accuracy and sensitiveness as any one of that class of instruments can be, but, like most voltmeters, it is subject to a serious temperature error. The method of correcting by switching in resistances, as described in our Notes, is, however, a rather barbarous device, if we may use so strong an expression. The automatic compensation by winding two circuits with wires of different temperature coefficients is not only simple, but perfectly successful. We understand that voltmeters when thus compensated do not vary one-tenth per cent. from the moment they are put on to the time they attain their maximum temperature, nor are they affected by variations of external temperature, but we believe that there is but little demand for them.

Digitized by Google

MANY of those who have followed the latest discoveries of electrical science appreciated the opportunity which was afforded on Sunday afternoon for making the acquaintance of Dr. HEINRICH HERTZ, of Bonn. A more pleasant and informal way of introducing a distinguished visitor than that adopted by Prof. AYRTON, at the Langham Hotel, it is difficult to imagine.

**The British Guiana Cable.**—We are informed that the Trinidad-Demerara cable is now repaired.

**Dublin.**—Extensive damage was done to the Dublin telephone wires by the heavy snow fall of the past week.

**The Aron Meter.**—Dr. Aron's electricity meter received a gold medal at this year's Exhibition at the Palais de l'Industrie, Paris.

**King's College, London.**—The Council of this College are ready to receive applications for the appointment of Demonstrator in Electrical Engineering.

**The Stations of the Metropolitan Supply Company.**—The automatic cut-outs described in our last issue are on the dynamo circuits, and not on the exciter circuits.

**Barnsley.**—The Town Council has adopted the minutes of the Park and Lighting Committee, which recommended the adoption of the proposed contract with the Westinghouse Electric Company.

**University College, Nottingham.**—The Committee of this College invite applications for the post of Junior Demonstrator in Physics. Further particulars will be found in our advertisement columns.

**The Telephone in Spain.**—The regulations hitherto in force that telephone lines were not to exceed 10 kilometres in length have been abolished, and concessions for longer lines will now be granted.

**The Ferranti System in France.**—The central lighting station on the Ferranti system, which came into operation at Troyes in August last, now supplies 2,000 lights, and is paying its way very satisfactorily.

**University College, Dundee.**—In consequence of Prof. J. A. Ewing's election to the Professorship of Mechanism and Applied Mechanics in Cambridge University, the Chair of Engineering at the above College will shortly be vacant.

**City and South London Railway.**—The Austrian Minister of Commerce has resolved to send two engineers to London to study the City and South London Railway, with a view to utilising the system on the projected Vienna Metropolitan Railway.

**Institution of Civil Engineers.**—At the last ordinary meeting of this Institution, it was announced that 14 Associate Members had been transferred to the class of members. Amongst the names we notice those of Dr. E. Hopkinson and Mr. Alexander Siemens.

**Old Students' Association.**—At the ordinary general meeting of this Association held yesterday, at Finsbury Technical College, a Paper was read by Mr. Hamilton Kilgour, member, on "Notes on Economy of Conductors in Systems of Distribution of Electrical Energy."

**Bristol.**—The Western Counties and South Wales Telephone Company have, as an experiment to the end of the year, connected the Bristol Messengers' Association to their exchange. By this arrangement subscribers can immediately obtain the services of a respectable and responsible messenger.

**Whitechapel Board of Works.**—On the recommendation of a large committee, to whom the matter had been referred for consideration, this Board has resolved to light the district by electricity, and to apply for a Provisional Order. It is proposed to employ the heat from the local destructor to generate steam.

**Chelmsford.**—At the last meeting of the Town Council, several members complained of the occasional extinction of both arc and incandescent lamps. It was decided that the Town Clerk should be instructed to write to Messrs. Crompton and Co. for an official explanation of the reason of the lights going out.

**Paddington Vestry.**—At the last meeting of this Vestry Colonel Barchard presented a report of the Electric Lighting Committee, and announced that the Metropolitan Electric Supply Company had deposited £20,000, and taken a site at St. Peter's Park, Amberley-road, and that the Company would commence work immediately.

**Hampstead Vestry.**—This Vestry has resolved to oppose all applications for electric lighting powers, and has empowered the Electric Lighting Committee to spend not more than one hundred guineas in obtaining a plan and estimate from an expert, with a view of guiding the Vestry as to the advisability of undertaking the work itself.

**Copper.**—The copper supplies for November have been somewhat smaller, while the deliveries have increased substantially, the total for the month amounting to 11,230 tons, as compared with 10,206 tons in October. The result is a further shrinkage in the stock, which now stands at 65,440 tons, whereas a year ago the total amounted to 99,984 tons.

**S. S. "Silvertown."**—This telegraph steamer, owned by the India Rubber, Gutta Percha, and Telegraph Works Company, is reported to have arrived at Coronel (Chile), on November 25th. It will be remembered that she carries the submarine cable for extending the Central and South American Telegraph Company's lines from Lima, where they at present terminate, to Iquique and Valparaiso.

**Platinum.**—The greatly-increased price of platinum, to which we referred in a recent issue, has naturally given rise to strenuous efforts, not only to find a satisfactory substitute, but to discover new mines. A few months ago Mexico was reported to be rich in platinum ores, and now the *Ballarat Courier* announces that ore has been found in Australia containing nearly 160lb. of platinum to the ton.

**O.S.A. Smoking Concert.**—A most enjoyable concert was held at the Masons' Hall Tavern, Basinghall-street, on Friday evening, November 28th. The programme included violin solos by Mr. Gatehouse and songs by Mr. Howden Tingey, Mr. John Barton, Mr. Gordon Heller, and a musical sketch by Mr. F. Charlton Fry. We understand that after Christmas there will be a series of entertainments of a similar nature.

**The Spanish-Morocco Cables.**—The firm of Pirelli, of Turin, have obtained the contract for the construction and laying of the cables connecting Spain with the Spanish stations on the coast of Morocco. According to *La Lumière Electrique* the contract price is £160 per mile, the money to be paid in ten equal annual instalments. During these first ten years the cables are to be maintained at the contractor's expense.

**Royal Institution.**—The Friday evening meetings of this Institution will begin on January 23rd, when a discourse will be given by Lord Rayleigh on "Some Applications of Photography;" succeeding discourses will probably be given by Lord Justice Sir Edward Fry, Professor J. W. Judd, Professor A. Schuster, Dr. E. E. Klein, Mr. Percy Fitzgerald, Dr. J. A. Fleming, Dr. Felix Semon, Professor W. E. Ayrton, and others.

**Electric Snow Ploughs.**—Twenty-five new electric snow ploughs, much heavier than those in use last winter, have been ordered by the West End Railway Company of Boston, and four of them are already completed. The new plough somewhat resembles a small freight car. It is six feet wide and eight feet long; the cab is eight feet long and seven and a-half feet high. The electrical equipment comprises two 15 horse-power motors.

**Sophia.**—Considerable discontent is said to have been expressed by the Bulgarian press at the manner in which the tenders for the electric lighting of Sophia have been dealt with by the committee charged with this matter. This committee is reported to have merely opened the tenders and accepted the lowest without further inquiry. A Budapest firm, presumably Messrs. Ganz and Co., are said to have sent in the lowest tender.

Digitized by Google

**University College, Aberystwyth.**—The workshop accommodation of the Physical Laboratory in the University College of Wales, Aberystwyth, has recently been considerably extended, and arrangements are being made for a course of instruction in electrical engineering. The recent additions include one of Messrs. Crossley's D high-speed engines, specially adapted for electric lighting, a Crompton dynamo (shunt and compound-wound), and a Crompton DD arc lamp, &c.

**Woking.**—The central station of the Woking Electric Supply Company is on the north side of the London and South-Western Railway, in the vicinity of the London and Basingstoke Canal, where substantial brick buildings have been erected, comprising boiler-house, engine and dynamo house, offices and stores, containing at present a plant capable of supplying 2,000 lights. The electrical plant comprises two Kingdon 60-unit 2,000 volt alternators. The mains are laid along the roadsides in stoneware pipes.

**The Tommasi Accumulator.**—An accumulator has been brought out by M. Donato Tommasi, the distinguishing feature of which is the use of hollow cylindrical perforated electrodes. Each cylinder is filled with active material, and closed at the bottom by an insulating plug, into which is screwed a rod running up the centre of the cylinder and terminating in a flat projection. The lids of the cells are slotted, and the cylinders are hung in rows from these metal-edged slots by means of the projections on their central conductors. Each row of cylinders constitutes an electrode.

**Long-Distance Telephony.**—A group of French and Belgian capitalists is offering to undertake the construction of a telephone trunk line between Berlin and Warsaw, a distance of about 360 miles. The estimated cost of the line is £360,000. The syndicate proposes to hand over the line after a certain number of years to the Russian Government. The charge is to be 6 francs for the first minute's conversation, and for every subsequent minute 25 per cent. less than the charge for the preceding minute, thus: two minutes' conversation for 10fr. 50c.; three minutes conversation' for 11fr. 50c., and so on.

**Local Authorities and Electric Traction.**—The North Metropolitan Tramway Company have received the consent of the London County Council to run electric cars over the northern portion of their line, which is controlled by the Council, during the term of seven years. The tramway company have also given notice of a Bill which they intend to introduce into Parliament, asking Parliament to compel the Local Authorities to conform to the Act, as passed last Session. At present the West Ham Local Authorities decline to grant more than one year's license, subject to 24 hours' notice.

**Electric Traction in Boston.**—Some idea of the magnitude of the operation of the electrical equipment of the West End Street Railway may be gained from the fact that from February 1, 1889, to July 31, 1890, the mileage of the motor cars was 3,121,689, and the mileage of towed cars 732,003.80, making the total mileage of cars dependent upon electricity for propulsion 3,853,692. During the seven days from August 10th to August 16th the electric cars carried on an average about 100,000 passengers per day, and at no time were there more than an average number of 150 cars in daily service.

**Long-Distance Business Communications by Telephone.**—A late experience of *The Electrical Engineer* has, says our New York contemporary, done more to inform us of the benefits of long-distance telephoning than any quantity of outside testimony could do. The business manager of the journal being away in Philadelphia, he called up the New York office, whereupon a big batch of morning mail was read to him and replies were dictated to a stenographer in New York. So successful was the experiment it has since been repeated more than once, and has become a practice on every such occasion.

**Poona.**—At the recent meeting of the Cantonment Committee, says the *Indian Engineer*, the scheme for the electric lighting of Poona was brought up for discussion. Messrs. Woodhouse and Rawson, of London, have offered to form a syndicate at home to raise two-thirds of the capital required, if the Cantonment Committee will guarantee the remaining one-third. The matter has been referred to a sub-committee for a report. In the meantime Government will be asked to say whether, if electric light is introduced into Poona, they would wish to have the barracks and public buildings similarly lighted.

**The American Government and the Telegraphs.**—In President Harrison's recent message to Congress the following passage occurs:—"I believe that the use of the telegraph by the Post Office upon proper terms is quite desirable. The Government does not own and does not operate railroads, and should not, I think, own or operate telegraphs. It would be quite practicable, however, to contract with telegraph companies as now with railroads to carry at specified rates what the senders designate. I recommend legislation to enable the Post Office Department to fairly test such use of the telegraph."

**The Electric Railway Advertiser.**—A significant indication of the progress of electrical traction in the United States may be found in the issue of a new weekly paper which contains a good deal of interesting matter, and is devoted to this branch of engineering. We find our recent editorial note on the Birmingham Tramway quoted with the following comment:—"There was a time when a similar misfortune was experienced in this country, and possibly the time is not yet wholly gone by. The adoption of electricity on street railways implies a complete change in road-bed construction, and any person that says the contrary is either an ignoramus or a liar."

**Dundee.**—At a meeting last week of the Committee of the Dundee Gas Commission a letter from the Board of Trade to the Clerk of the Gas Commission was read, in which attention was called to the provisions of section 10 (1) of the Dundee Electric Lighting Order, and to the necessity of obtaining the approval of the Department to the system upon which energy was to be supplied; and to request that as soon as the undertakers were in a position to do so they should furnish the Department with a description of the system of supply they propose to adopt. The Clerk was instructed to reply that notification would be made to the Board of Trade as soon as a system of supply was decided on.

**The General Electric Power and Traction Company.**—We hear that the General Electric Power and Traction Company are now offering to supply cars and the electrical equipment to tramway companies, and to maintain the motors, switches, gearing, and accumulators at a mileage rate, the tramway company operating the road at their own expense. The result of the experience at Barking enables the General Electric Traction Company to undertake electric plant maintenance at such a price that, including the cost of generating the power, &c., traction by accumulator cars will be less costly than that by horses. The company is at present in negotiation with some of the largest tramway companies in the country on these lines.

**Electric Lighting Provisional Orders.**—Up to November 30th 76 electric lighting orders had been advertised and the plans deposited. Of these 17 seek power to light various portions of London and the suburbs. As regards the proposed orders which relate to the metropolis the areas sought to be lighted are the City of London, St. Saviour's, Southwark, St. Giles's, Camberwell, Paddington, St. Mary, Islington, Hampstead, Whitechapel, Hackney, Shoreditch, St. Martin-in-the-Fields, St. Margaret and St. John, Westminster, St. Luke, Chelsea, St. George's, Hanover-square, and portions of the parishes of Clerkenwell, Wandsworth, Putney, Clapham, and Balham. The total number of orders which reached this stage last year was 159.

**The Paris Telephone System.**—Our esteemed contemporary, *L'Electricien*, devotes considerable space in a recent issue to detailing the improvements which have been made in the Paris Telephone System since it has been taken over by Government. One of these improvements is that subscribers are no longer obliged to go to the nearest office in order to pay their subscriptions, but may pay them at their own houses, though 25 centimes extra is demanded for this privilege. More substantial benefits are the reductions of rentals and the increased rapidity in effecting connections, and that these have been appreciated is evident by the large augmentation of the

Digitized by Google

*clientèle.* On October 1, 1889, there were 6,300 subscribers to the Paris Exchange, on October 1, 1890, there were 7,800, an increase of nearly 24 per cent.

**The Weston Temperature Compensator for Electrical Measuring Instruments.**—In order that temperature variations may be compensated for Mr. Weston, says the *Electrical Engineer* of New York, provides a thermometer with them, the bulb of which is elongated and curved round the exterior of the coil. The thermometer-tube is bent and curved under the scale-plate. By means of this thermometer the temperature of the coil is shown under the regular scale-plate of the instrument. Provided with each instrument and inserted in its circuit is a series of resistances, which can be switched in or out as desired by turning a handle. The contact-plates of these resistances are marked in degrees of the thermometer. In practice, therefore, it is simply necessary to note the indication of the thermometer and place the switch on the contact-plate corresponding to that indication in order to keep the resistance of the circuit in the instrument uniform.

**The De Beers' Mine Central Station.** — The installation for the lighting of the underground workings of the Central Diamond Mine has just been completed, under the superintendence of Mr. R. Oliver G. Drummond. From the second annual report for the year ended March 31st, we find the De Beers' mine circuit had been running about 15½ months, night and day, with the exception of a short stoppage on Sundays, and there had been no cessation to the light during working hours, except once, when the engine had to be stopped for ten minutes. The plant, from which the Central Mine is worked, is situated within the mining area of the De Beers' mine, and the Company have obtained the right to run their wires through the busiest thoroughfares of the city, so that they have every facility for lighting the Club, Public Library, Post Office, Court House, and their own private central offices in the Diamond Market. The Masonic Temple is already lighted from the De Beers station, and, although more than a mile distant, by a system of electrical signals and switches each ceremony isme thodically illuminated, according to ancient custom, without the slightest hitch.

**The Corporation and the City and Guilds of London Institute.**—At a meeting of the Common Council on Thursday last week, Mr. Lee moved the adoption of the report of the Coal and Corn and Finance Committee, recommending a grant of £500 out of the City's cash to the above Institute. Mr. Deputy Bedford considered that the voting of this amount would be a waste of money, and moved an amendment to that effect. Mr. Sly, in opposing the recommendation, referred to the small number of students at South Kensington, and said that those who were to blame ought to be ashamed of their efforts, and ashamed of the result. Mr. Morrison supported the action of the Committee, and stated that they would bring up a report which would be satisfactory, he believed, to every member of the Court, and to every one outside it. Mr. Shaw appealed to the Court to continue in the good work it had been doing in support of the cause of technical education in London. Alluding to what was being done at Finsbury College, he said so great was the number of students that there was not room for one more, but arrangements were being made whereby extra accommodation could be secured for another 50 students. There were 108 day students, and 1,006 evening students. The amendment was negatived by 85 votes to 31.

**Railway Rates.**—A general meeting of the Mansion House United Association on Railway Rates was held at the Guildhall on Friday afternoon last. Alderman Sir James Whitehead presided. The Corporation of London, the London Chamber of Commerce, numerous county councils, municipal corporations, local authorities, trading and agricultural organisations, and mercantile firms were represented. The report made to the Board of Trade by Lord Balfour of Burleigh and Mr. Courtenay Boyle, and the classification of merchandise and schedules of *maximum* rates and charges proposed by the Board to be applicable to nine of the leading railway companies, together with the figures supplied by the railway companies to the Board of Trade respecting the alleged effect of the proposals, were considered by the meeting, which unanimously resolved that (1) it is equitable that the railway companies' present powers should be reduced; (2) that *maximum* rates should approximate more nearly than at present to the actual charges. The meeting further resolved (1) that this Association is unable to accept the proposals of the Board of Trade as being "just and reasonable," and will use every means in its power to prevent their authorisation in their present form by Parliament; (2) that Parliament be respectfully urged to require the railway companies to prepare and issue returns showing the rates charged for the conveyance of staple articles of merchandise, and the tonnage of articles carried at these rates during the year 1889 between the most important trade centres in the United Kingdom.

**Mr. Cyrus W. Field.**—Mr. Cyrus Field, who was one of the most prominent originators of the work of connecting England with the United States by telegraph cable, on the 2nd instant celebrated his "golden wedding." The occasion was gladly availed of by his friends in this country to present him with an illuminated address to commemorate that event, and recall the part he played, in conjunction with Sir John Pender and others, in connection with the bridging of the Atlantic by the electric wire. The result was the signing of the address given below by a number of distinguished persons not necessarily connected with telegraphy, as well as by those who were associated with the laying of the first ocean cable. The contents of the address and the names of the signatories were appropriately telegraphed over one of the Atlantic cables on Tuesday last, the fiftieth anniversary of Mr. Field's marriage :—

"To Cyrus W. Field, Esq., Gramercy Park, New York.

"Dear Sir,—We, the undersigned, who have known you for many years, and some of whom have been long and intimately associated with you, desire to express to you and to your amiable and devoted wife our earnest and heartfelt congratulations on your golden wedding day, the 2nd December, 1890. We earnestly wish you both many years of health and happiness, enjoying the fruits of your useful and well-spent lives, and seeing on every side the wide-spreading development of the Submarine Telegraph enterprise in which you, Mr. Field, have laboured so long, so zealously, and so successfully. This great work, pursued by you with unflagging energy and perseverance for many years through the greatest difficulties and hindrances, has now become a first necessity of national and commercial life, and you have the profound satisfaction of knowing that its objects and its results are and ever have been peaceable and beneficent in their character. We ask you to accept this message of our goodwill and good wishes which will be sent to you both over and under the sea.

Very faithfully yours, Argyll, Frederic W. Farrar, Monck, W. E. Gladstone, W. H. Russell, Douglas Galton, Tweeddale, F. A. Bevan, H D. Gooch, W. Thomson, G. Shaw-Lefevre, J. Russell Reynolds, John Pender, James Anderson, W. Cunard, William Ford, George Elliot, Geo. Henry Richards, W. Shuter, Henry Clifford, Henry C. Forde, W. Andrews, H. Weaver, G. von Chauvin, J. H. Carson, Samuel Canning, Richard C. Mayne, W. S. Cunard, Julius Reuter, H. A. C. Saunders, G. W. Campbell, H. M. Stanley, of Alderley; Margaret Anderson, John H. Puleston, George Cox Bompas, James Stern, H. L. Bischoffsheim, Louis Floersheim, T. H. Wells, J. H. Tritton, W. H. Preece, C. W. Earle, Catherine Gladstone, J. S. Forbes, Caroline Roberts van Wart, G. W. Smalley, Gerald Harper, William Barber, George Grove, Jane Cobden, Thomas B. Potter, Charles Burt, Robert C. Halpin, Edward Satterthwaite, Frank H. Hill, J. C. Parkinson, Richard Collett, W. Leatham Bright, C. W. Stronge, Latimer Clark, R. T. Brown, William Payton, Henry Dever, Lewis Wells, John G. Griffiths, Robert Dudley, Kenneth L. M. Anderson, Julian Goldsmid, John Chatterton, John Temple, Jane E. Lloyd, Frances Baillie, Montague McMurdo, Willoughby Smith, Philip Rawson."

The following reply was received from Mr. Field :—

"All my friends here were much pleased with the address; please thank for me everyone that signed it. I wish that I could thank them in person. Mrs. Field joins me in all kind wishes."

As a further memento of Mr. Field's connection with the first cable across the Atlantic, a piece of teak from the "Great Eastern" has been handsomely mounted as a walking-stick for presentation to him. On the top a small sketch of the "Great Eastern" has been engraved, and on a band encircling the stick, "Portion of the 'Great Eastern,' broken up 1890. Cyrus W. Field, Esq."

## ELECTRICAL DISTRIBUTION BY TRANSFORMERS FROM CENTRAL AND ECCENTRIC STATIONS.*

BY DR. J. A. FLEMING, M.A.

*(Continued from page 44.)*

### THE THOMSON-HOUSTON TRANSFORMER SYSTEM.

§ 1. In the United States one of the most widely known of all the electric lighting companies is that of the Thomson-Houston Company, having its headquarters in Boston, United States. Commencing in 1880, and having in 1882 only a small factory at New Britain, Conn., this corporation has developed its electrical manufactures at a steadily increasing rate, and has at the present time an immense factory at Lynn, Mass., occupied in the production of electric lighting plant for arc and incandescent lamps, as well as for electric locomotion. In the United States over 50,000 arc lamps are operated by the well-known Thomson-Houston continuous current arc light dynamo, in some 600 or more stations. The ingenuity and remarkable inventive skill of Professor Elihu Thomson has been also brought to bear on the development of an alternating transformer system, with the result that nearly 100,000 incandescent lamps are in use (1890) in the United States in connection with a transformer system as devised by him. The alternating dynamo employed in the Thomson-Houston transformer system presents some interesting peculiarities.

Fig. 1 shows the general form of all the dynamos for generating alternating currents manufactured by the Thomson Houston Electric Company. The field magnets are of cast iron, and are made in two parts, the lower one bearing the pedestals for the armature bearings. Each casting carries projecting inward from it one-half the total number of radial pole pieces. The number of polar projections varies from eight in some of the smaller sizes to twenty-two in the largest. The armature is a laminated iron cylinder, and has applied to its surface a set of flat coils which form one layer of double-insulated copper wire of square cross section. This armature winding, then, consists of a number of flat oval coils, equal in number to the number of polar projections, wound in a lathe on special formers. There is a space of three-quarters of an inch or more in the centre of each coil which, in some machines, is filled with insulating slip or core, and in others with a second separate coil used for exciting the field of the dynamo. The armature coils are securely bound to the armature core by brass wire, and are covered with insulating strips of mica. These coils are either connected all in series and in series with the external circuit, as is shown in Fig. 2, in the case in smaller sizes of high potential machines, or they are wound, as shown in Fig. 3; *i.e.*, two groups in multiple, consisting of an equal

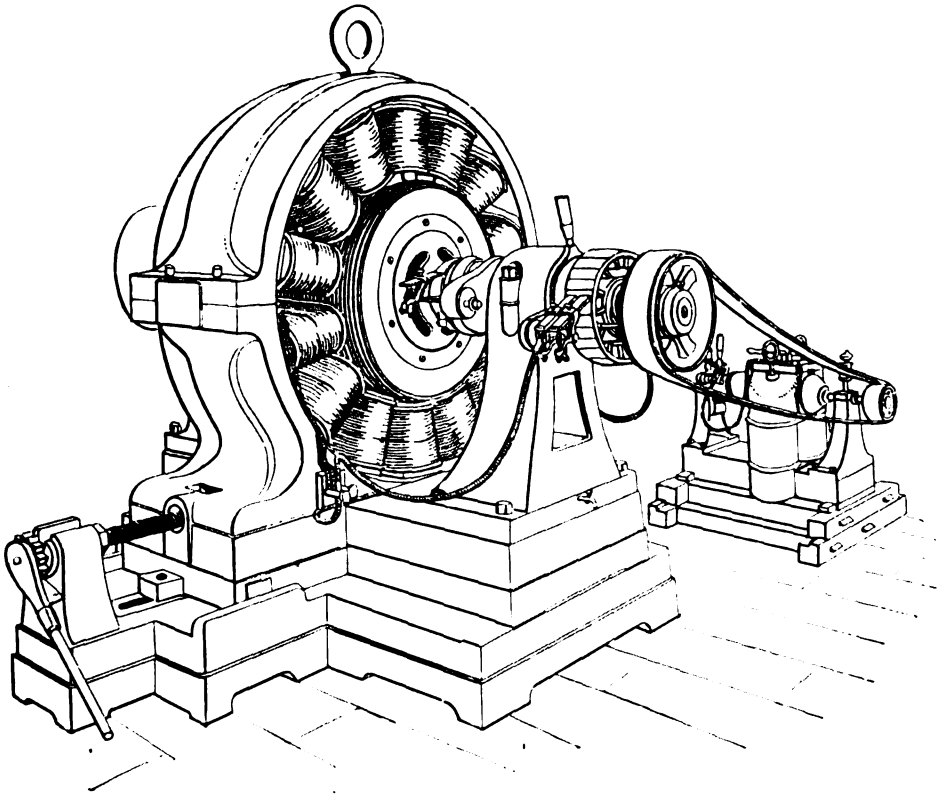

Fig. 1.—The Thomson-Houston Alternator.

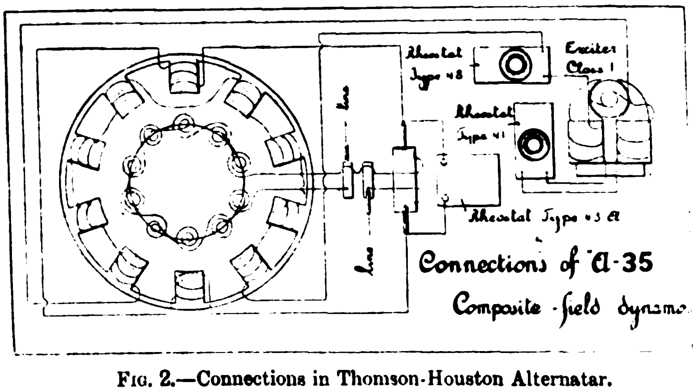

Fig. 2.—Connections in Thomson-Houston Alternatar.

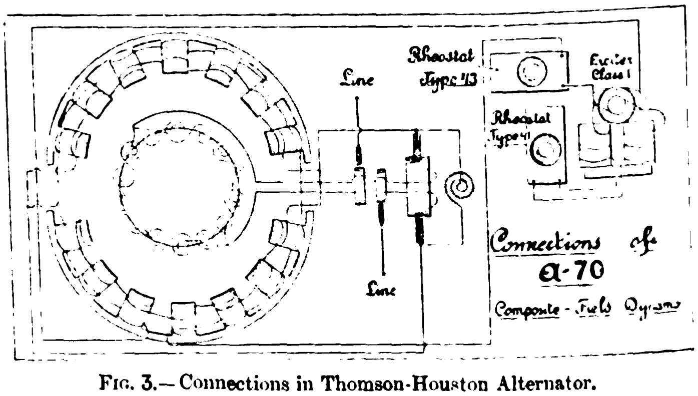

Fig. 3.—Connections in Thomson-Houston Alternator.

* All rights are reserved.

Digitized by Google

number of coils in series. By this means a 1,300 light armature is wound wire of the same size as a 650 lighter.

The armature core, in these machines, is built up as usual of thin iron sheets perforated with apertures through the centre, so as to allow a circulation of air.

These alternating current dynamos are made in three types, as follows:—

(i.) Self-excited.
(ii.) Separately-excited.
(iii.) Composite-wound.

(i.) *Self-excited Type.*—In this class of dynamo, which has been now more or less discarded in favour of the third mentioned, the field-exciting coils are coils wound about the armature in a manner like the ordinary Siemens' winding, and consist of but a very few turns of square copper wire. These coils are arranged as shown in Fig. 4, and they lie beneath the main armature coils and fill the spaces on the surface of the iron core between the wires of the flat or "pancake" coils as they are sometimes called. The upper sketch in Fig 4 shows the manner in which these coils are wound over the ends of the core, the two opposite coils being either connected in series or in multiple arc and their terminals brought out to a commutator on the shaft outside of the bearings at the collector end of the dynamo. This commutator has as many segments as there are poles on the dynamo, and the two terminals of the field exciting circuits on the armature are connected to alternate segments. The exciting current is controlled by a rheostat in its circuit mounted upon the switch-board, and in this circuit are included

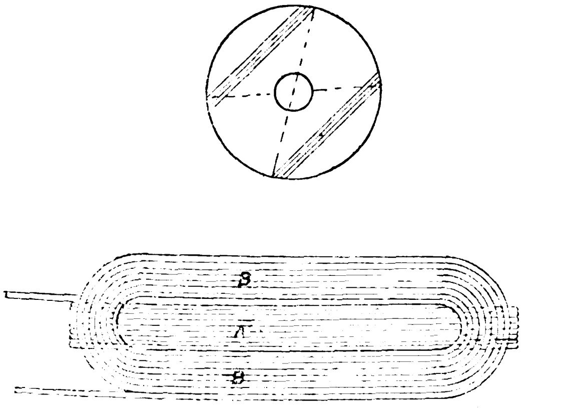

Fig. 4.

the coils on the field magnets. This design may, in fact, be described as an alternate-current armature winding on the top of a continuous current winding. This last supplies current for the field.

(ii.) *Separately-excited Type.*—The separately-excited dynamo is of the same form as the self excited, the only difference being that in it the commutator and armature exciting coils are absent. It is used with an exciting dynamo, such as shown in Fig. 1.

(iii.) *Composite-wound Type.*—The term "composite" as applied to the third type of the alternating current dynamo of the Thomson-Houston Electric Company was adopted to distinguish this arrangement of field excitation from that employed in direct current machines, which consists in the combination for producing the magnetic field of the main armature current with a derived current shunted around the external circuit. The arrangement of circuits which is used on the most improved type of Thomson-Houston alternator for maintaining a constant difference of potential at a defined point of distribution, regardless of load, is shown in Figs. 2 and 3.

A part of the magnetic field is maintained by means of current from a separate or exciting dynamo. If the load upon the outside circuit is increased it is necessary to increase the magnetism of the field, in order that the machine may in turn supply the increased demand in the circuit, and the lights remain steady.

This is accomplished in other machines by varying the current on the field magnets by a rheostat or variable resistance operated by hand. In the Thomson-Houston dynamo, however, the same result is obtained entirely automatically by passing the greater portion of the main current through two or more of the field magnets, thus energising the machine in exact accordance with the demands made upon it. As an alternating current is not suitable for magnetising the fields it is necessary to change the character of the current produced in the armature to a direct current before passing it through the special winding on the field, and this is done by a commutator at the end of the shaft. By this regulation the attention required at the dynamo is reduced to a minimum, while at the same time the efficiency of the machine is increased, and any number of lamps, from one to the full capacity, may be thrown on or off without in any way affecting the steadiness and brilliancy of those remaining.

To allow for a pre-determined percentage of loss in the wiring, it is necessary, as the load is increased, that there should be a definite amount of increase in potential, which is accomplished by placing around the field winding for the main current a resistance which shunts that portion of current not required for regulation.

It is precisely the same in principle as the compound winding in the case of a continuous current machine. In addition to the current derived from a small direct current separate exciter, a second current, which is a rectified portion of the main current, is used to energise the fields. This current, being proportional to that in the external primary circuit increases the field strength, and thus the potential with increasing load.

It will be seen from the diagrams of the connections that the armature current is "rectified" for a part of its course by means of a commutator having as many segments as there are field poles on the machine—alternate segments being connected together, and one set connected to one armature terminal, and the other to the external circuit.

This rectified current is either used to excite two of the polar projections, as in Fig. 3, or to partially excite all of them, as in Fig. 2, the latter method being the most approved.

Before each machine is sent out from the factory, the strength of the compounding current is regulated by means of a German silver shunt fastened to the frame of the machine. By changing this shunt the machines may be made self-regulating for any required line resistance or drop, being over-compounded to whatever degree is needed. The winding may be described as that of a "compounded" alternator for giving constant potential at the ends of a line.

The following table gives the sizes and capacities of the machines of this type thus far constructed, with the exciting and main current of each:—

| Alternator. | Watts. | Lamp load in 16-c.p. lamps. | Exciting circuit. | | Weight. | Speed. | Floor space (inches). | Output in amps. |
|---|---|---|---|---|---|---|---|---|
| | | | Volts. | Amp. | | | | |
| A 35 | 35,000 | 650 | 100 | 5·8 | 3,570 | 1,500 | 66 × 45 | 35 |
| A 70 | 70,000 | 1,300 | 100 | 11·2 | 8,270 | 1,070 | 84 × 56·5 | 70 |
| A 140 | 110,000 | 2,600 | ... | ... | ... | 680 | 80 × 105 | 140 |

Each machine yields current at 1,000 or 2,000 volts as required.

For the purpose of energising the field magnets the dynamos are furnished with small exciting dynamos of the direct-current type. It has been found desirable in some special cases to make the smaller sizes of alternating-current dynamos self-exciting, and to this end the armatures are wound with an extra or special coil for furnishing current to energise the fields. The exciter is usually placed, as shown in Fig. 1, behind the alternating dynamo, driven by a belt from a small pulley attached to the armature shaft. One exciter is usually employed with each alternating-current dynamo, but when several dynamos are operated in the same station, it is often found more convenient to employ exciters, any one of which is of sufficient capacity for all the machines. By this arrangement an accident to one exciter need not affect the general service.

Digitized by Google

Exciting dynamos are made in the following sizes :—

| lass | Volts. | Amperes. | Speed. | Weight. | Pulley Diam. | Pulley Face. | Floor Space. |
|---|---|---|---|---|---|---|---|
| 0 | 100 | 12 | 2,300 | 307 | 4 | 2 | 24 × 13½ |
| 1 | 100 | 24 | 2,200 | 480 | 5 | 3 | 29¼ × 16⅛ |
| 2 | 100 | 40 | 1,800 | 696 | 6 | 4 | 31¼ × 18¾ |
| 3 | 100 | 60 | 1,600 | 1,080 | 8 | 5 | 37¼ × 21¾ |
| 4 | 100 | 80 | 1,600 | 1,364 | 8 | 6 | 40 × 23⅜ |

The current required in the fields of the alternating-current dynamo is is follows :—

A-35 Composite Field, 5·8 amperes.

A-70 Composite Field, 11·2 amperes.

*(To be continued.)*

## DRUM ARMATURE WINDING.

BY F. M. WEYMOUTH.

*(Continued from page 101.)*

Further developments of this form of evolute end winding are to be found in the "Westminster" dynamos of Messrs. Latimer, Clark, Muirhead & Co. This firm, under the supervision of their electrical manager, Mr. F. V. Andersen, have employed conductor bars built up of either wire or tape, and sometimes both kinds on one armature. Fig. 18 shows a longtitudinal section through an armature of this latter description. The long bars *a a* are of copper strips laid edgeways, and each strip insulated with varnish. The short bars *b b* are of wire laid parallel, each wire insulated with shellac varnish, and the whole group cranked at both ends. An end thus cranked is given to a larger scale in Figs. 19 and 20.

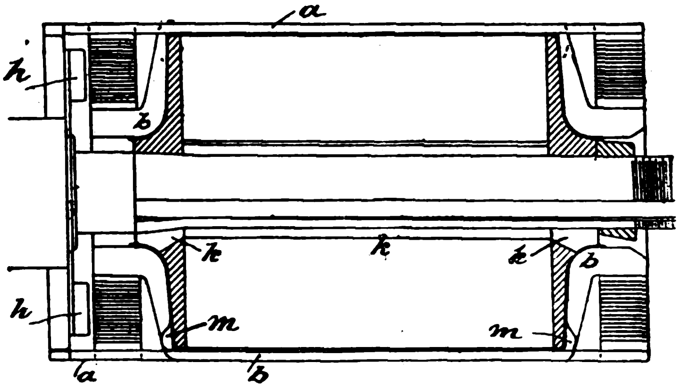

FIG. 18.—Andersen Winding. Longitudinal Section through Armature.

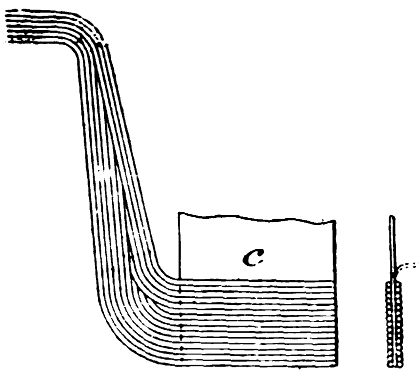
It will here be seen how the cranked end is splayed out, so that the wires embrace the inner end of an evolute strip *c*, and are soldered to it in a single layer on each side, as shown more clearly in the end view (Fig. 20). The wires are the more carefully spread over the end of the strip *c* that the soldered joint may be as large as possible, and so offer a minimum resistance. A transverse section through the conductor bars on the periphery of the drum is given (Fig. 21), showing their compound formation alternately of copper strip and wire. Each bar is insulated with varnished tape. The layers *a a* are of Willesden or Manilla paper, varnished, and *b* is the usual exterior band of steel wire. The evolutes, duly insulated from each other, run from the inner cranks outwards to the long copper strip bars opposite, as in the case of the Crompton-Swinburne winding, shown in Fig 12. The conductor bars are here jointed at both ends to other metal, the several wires or strips in each are consequently in metallic contact at each end. They need to have a half-twist given them in the middle, in the manner already referred to when discussing the subject of Foucault currents. In Fig. 18, *h h* are fan blades for drawing air through the core by airways *k k*, of which there are three. In subsequent machines, however, these blades have been omitted, the suction caused by the commutator lugs being considered sufficient. The winding is held from slipping by a crown of teeth *m m* on each end plate, between which the cranks lie. A burnt section, however, cannot be taken out without dismounting



FIGS. 19, 20.—Andersen Winding. Cranked Ends.

at least half of the winding. This firm has made machines with the conductors formed of copper tape only. As these are necessarily laid edgeways, and will not consequently easily bend, the cranks have to be formed of pieces soldered and rivetted together, in the manner shown in Figs. 22 and 23, the latter being a sectional plan on *a b* in the former to twice the scale. For the greater flexibility of the evolutes *c* these are here made of two thin strips of copper, instead of one, as is shown clearly in Fig. 23. Although this is of somewhat more simple construction than the wire-made cranked bars, inasmuch as these latter have to be carefully formed up in a mould, yet two extra joints are introduced.

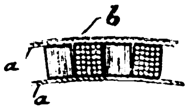


FIG. 21.—Andersen Winding. Transverse Section through the Conductor Bars on the Periphery of the Drum.

It will be observed that these evolute windings so far represented have one common advantage. They are made entirely of rolled copper in one form or another. Hence all desired lengths need but to be cut off, with a minimum of waste, both in material, labour, and use of machinery. On the other hand, comparatively speaking, the subsequent construction of the end winding is not exactly simple. In one method of pro-

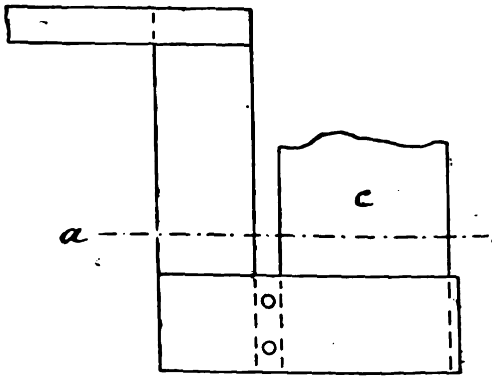

FIG. 22.—Andersen Winding. Cranks.

cedure, the short bars have first to be made up separately, with cranked ends, and with the connectors, as yet straight, duly attached to each crank, and lying in the same plane with it. These, thus far individually complete, are then laid in position on the core, and temporarily bound on, with the connectors projecting radially all round. By roping and so forth, all the connectors at one end are now forced round in a com-

Digitized by Google

bined mass, each one naturally assuming an evolute curve, until the outer end of each reaches the opposite side of the core end to that from whence it started, as shown in Fig. 11. Being held thus, and the connectors at the other end of the armature having been treated similarly, the long bars are finally added, and severally jointed up to their respective connectors. Hence, by the magnitude of the operation as a whole, it will be seen that the first-named advantage in the use of rolled copper is in some measure lost. One of the principal points, however, in this winding, as compared with Edison's discs, is, that there is a minimum electric pressure between the evolutes.

The evolute end windings we have thus far discussed, it may now be noted, have the peculiarity that each evolute from beginning to end is approximately half a circle. In another class of evolute winding, however, each evolute is approximately only a quarter circle, and the crank system is absent.

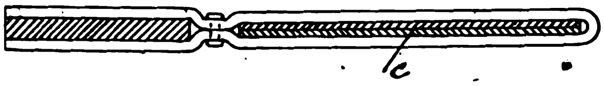

Fig. 23.—Andersen Winding. Sectional Plan on *ab* of Fig. 22.

This design was first brought out by Herr Hefner von Alteneck, and is that adopted by Drs. J. and E. Hopkinson in the manner represented in Figs. 24 to 27. Fig. 24 is a longitudinal section through an armature wound with one

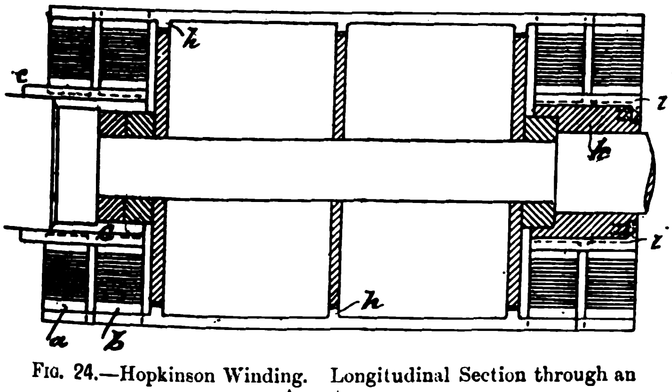

Fig. 24.—Hopkinson Winding. Longitudinal Section through an Armature.

turn per section. Fig. 25 is an end view, but showing only a portion of the winding for the sake of clearness. The bars, it will be noted, are solid, the heating being obviated in the manner already described, by enlarging the air space under the horns of the pole-pieces. The parallel conductors in this case also are short and long. But instead of the short ones being cranked at their ends, they are jointed to evolute strips as well as the long bars. There are thus two series of evolute strips side by side, as shown at *a* and *b* in the illustrations.

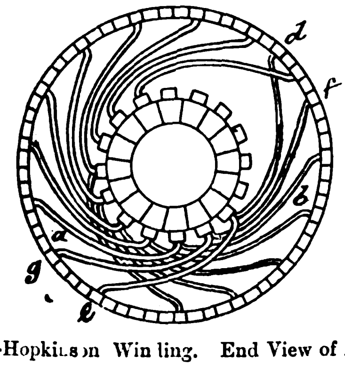

Fig. 25.—Hopkinson Winding. End View of Armature.

The evolutes in the one, however, run round in the opposite direction to those in the other, as shown in Fig. 25, and only cover an angle of approximately 90 degrees instead of 180 degrees. On each commutator segment a bar *c* is screwed, which projects within the end winding in a direction parallel with the shaft. To this the interior end of one connector in each series is screwed or otherwise jointed, thus connecting a long bar on the one side to a short one opposite, as, for instance, *d* and *e*, or *f* and *g*, as shown in Fig. 25. Figs. 26 and 27 show this arrangement duplicated for a winding of two turns per section, when there are four series of evolutes at each end. The driving of the winding is effected by means of snugs formed in some or all of the bars themselves, which fit into recesses in the peripheries of the end

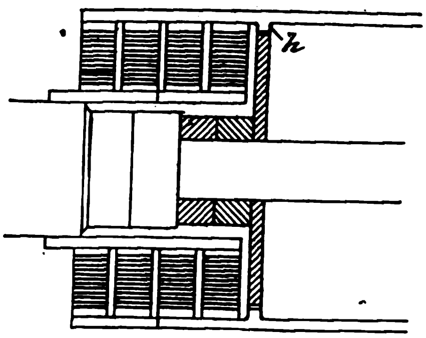

Fig. 26.—Hopkinson Winding. Two Turns per Section.

plates and a middle disc, as shown at *h h* in Figs. 24 and 26. At the pulley end of the armature, there being no commutator bar for the strips to be fastened to, an annular block of insulating material *k* (Fig. 24), is run on the shaft, and on this bars *i i*, parallel with the shaft, are screwed for the purpose, the screws being put in at the outer end turned inwards radially to receive them. It will be noted that with this method of two or four series of evolutes, all the parallel bars are straight, without bends, and their joints being all external and accessible, any can be removed separately. This latter advantage, however, does not appear to apply to the evolutes, should any of these require renewal. A minimum pressure exists between adjacent evolutes in any one series, as with the method of Messrs. Crompton and Swinburne. Likewise, also, the winding is symmetrical, tending to a good balance, and the separate sections are all the same length round, and consequently of the same resistance. This winding is also constructed of rolled coper.

We now come to another winding, the end connections of which are designed on the principle of a double series of evolutes, running in opposite directions, similarly to the last described. This is Eickemeyer's, of New York. Although like in principle to the Hefner von Alteneck method, it is in other respects altogether different. Each section of coil is composed of wires laid together, and contains no joint in it from one end at one commutator lug to the other end at the next lug. Each section, moreover, is entirely self-contained, and is formed to the right shape and curvature on a mould, or in part on a mould, before being put on to the armature. Thus the coils on any armature are exactly similar, and consequently interchangeable. Here, as with the Siemens' wire winding, a high-pressure small current can be obtained by making each

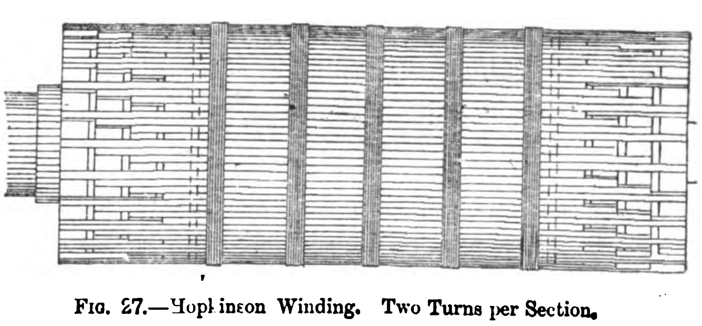

Fig. 27.—Hopkinson Winding. Two Turns per Section.

section, of one wire, carried round it several times, with the two wire ends united to the commutator. Or the wires can, however, be united in parallel, each section thus consisting of a group of wires carried round once, and all their ends united to the commutator—all the wire ends, that is, at one end of the group being jointed to one commutator lug, and all the other ends united to another lug. Or, again, a section composed in

Digitized by Google

the aggregate of many turns of wire may be made up of a group of a few wires in parallel carried a few times round in series.

Figs. 28 to 31 are views of an armature fitted with a simple winding of two turns per section. Fig. 28 is an elevation; Fig. 29 is an end view with the commutator removed, leaving a section on line, *p q*, in Fig. 28. Fig. 30 is a plan of one coil, and Fig. 31 an isometric perspective view of the same. The portions lettered *b b* in Figs. 30 and 31 correspond to the outer parallel bars that lie on the periphery of the core on opposite

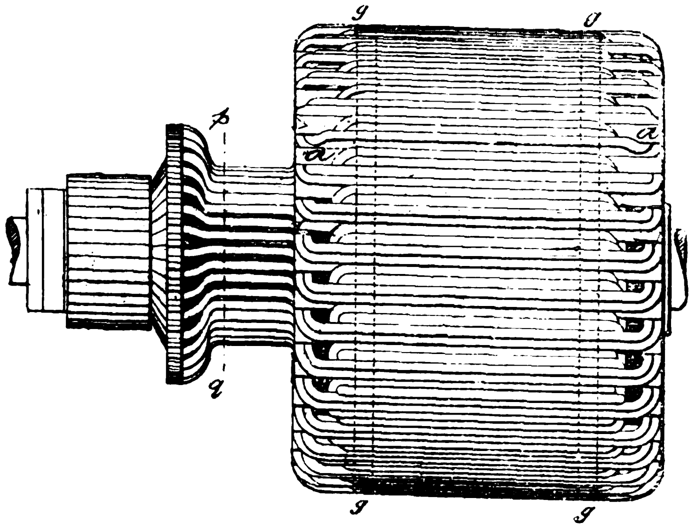

Fig. 28.—Eickemeyer Winding. Elevation of Armature.

sides of the armature. The parts, *c c* (Fig. 30) lie across the ends, and correspond to the connectors. It will be observed in Fig. 31 that the downward angles, *d d* (Fig. 31) are arranged to approach the shaft; while the swelling shoulders, *e e e e*, on either side will form the evolutes right and left as shown in Fig. 29. As the current here is small, and the sections not numerous, the commutator is also small as compared with the armature. Hence the connections *f* to the commutator are led off from one of the interior angles *d*. The pins, *a a*, in Figs. 28 and 29 are to drive the winding. The dotted lines,

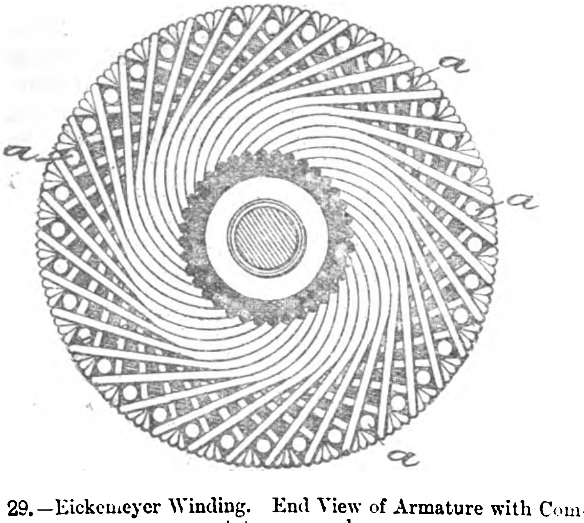

Fig. 29.—Eickemeyer Winding. End View of Armature with Commutator removed.

*g g*, in Fig. 28 represent the exterior binding wires. In Fig. 30 it will be observed that one side, *b*, is longer than the other, thus, in fact, forming our "long" and "short" bars. This allows room for the two series of evolutes at each end of the armature; also, when putting the coils on the core, the small side of one coil can easily be passed within the large sides of other coils, and so allow of their being got into position.

In Figs. 32 and 33 an arrangement is shown of many turns per section for a small current of high voltage. Two coils are here represented, one of them being dotted in Fig. 32, but both shown in full in Fig. 33. It will be seen here clearly how the small side of the one fits within the large side of the other, leaving the clearance space *a a* between. The wires in the parallel bars are laid 4 × 2, while in the convolutes portions they are all eight abreast, lying in curved planes parallel with the shaft. The "short" bars, it will be observed, are here intended to form a complete layer by themselves on the core *m m*, while the "long" bars are arranged outside. The two sides of a coil thus come exactly opposite instead of only nearly so. As the two layers will be exposed to a maximum difference of potential between them, they need to be well insulated from

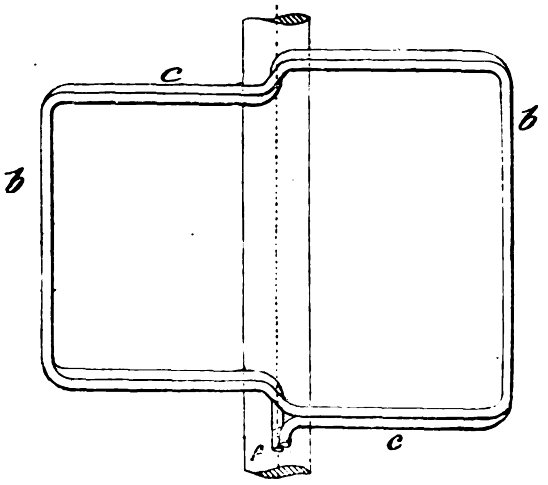

Fig. 30.—Eickemeyer Winding. Plan of a Single Coil.

each other. This insulation, and the taping round the bars, are omitted in the sketches for the sake of clearness. In Fig. 33 the section through the bars of one coil is shown in solid black, *b b*, while through the other coil the wire sections are left clear circles, as shown, *c c*. The connection to the commutator is led off from the middle at *f* (Fig. 32).

In Fig. 34 this same winding is shown, but with the wires in each coil all united in parallel for a large current. As the commutator will now need to be larger it will be more convenient to lead off the connections to it from the outside of the coils, as shown at *g*, rather than from the middle. This view, being a longitudinal section through the armature, also gives sections through the two series of evolutes at either end, showing clearly their mutual positions, and the air spaces *a a* between them effectually insulating one from the other. The semi-circular portions *d d* are the same as those similarly lettered in Figs. 32 and 33, where it will be seen that they lie in radial planes.

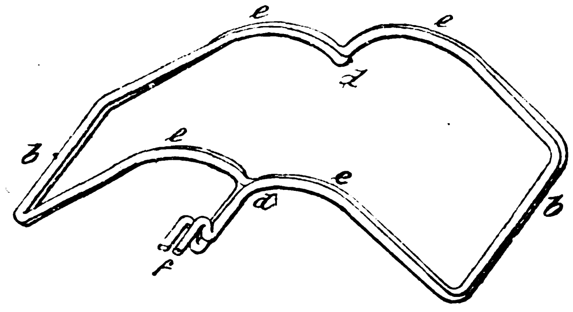

Fig. 31.—Eickemeyer Winding. Isometric Perspective View of a Single Coil.

A few words on this point of the air insulation. Our remarks will also apply to the Crompton and the Alteneck end-windings. This point, indeed, as has already been hinted at, constitutes one of the chief considerations of these special forms of end-winding. When adjacent coils are approximately in the plane of commutation, the "long" bar of one will be in connection with the commutator segment in contact with one brush, and the "long" bar of the other coil will similarly be connected to the other brush. Let the brushes be top and bottom, and the upper one positive. Using Fig. 34 for illus-

Digitized by Google

tration, we shall now find that the bar *b* is at its highest pressure delivering current to the brush; while the bar *c*, being a side of the coil connected to the negative brush, is at a minimum pressure. Hence the two bars *b* and *c* are lying close together, with a maximum difference of pressure between them. On the other hand, as the volts only gradually rise in one long bar after another as they approach in order from the bottom to the top on both sides of the armature, it comes about that there is only a minimum pressure ever between adjacent long bars or adjacent short bars. At the end of the armature, all the short bars are connected to the series of evolutes or radial cranks formed next the core ends; while all the long bars are united to the outer series. Hence there is only a minimum pressure between

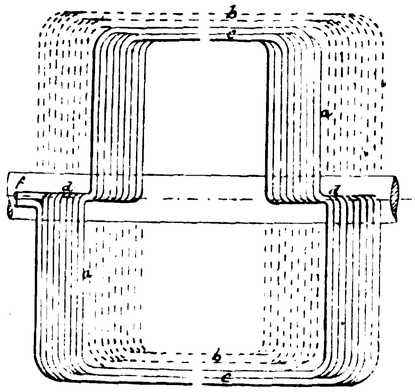

FIG. 32.—Eickemeyer Winding. Several Turns in Series per Section. Side View of Two Coils.

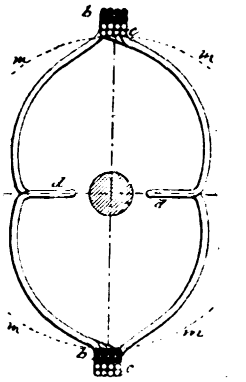

FIG. 33. — Eickemeyer Winding. Several Turns in Series per Section. End View of Two Coils.

adjacent connectors in the same series; and any connectors proceeding from the ends of two adjacent long and short bars, with maximum volts between them, pass each into different series of evolutes, where they are effectually insulated by the air spaces *a a* between them. Thus it will be seen, that while good insulation can well be put between the two layers of bars on the periphery, or the bars can each be well taped, without increasing the total size at all; among the connectors, where they are apt to be cramped for room, only slight insulation is needed between those in one series. Hence, of the total mass of a series of evolutes, a much larger proportion can be allowed for the copper than might otherwise be the case.

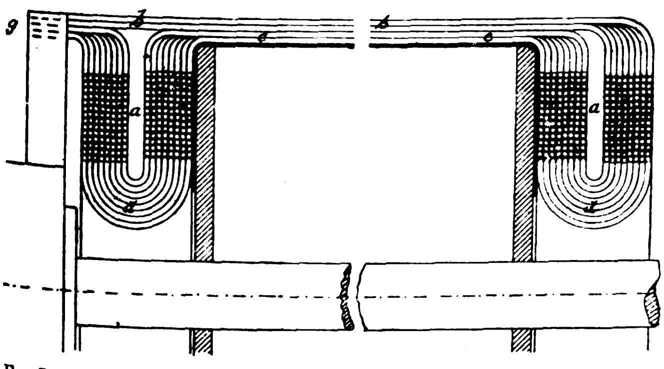

FIG. 34.—Eickemeyer Winding. Several Turns per Section, all in Parallel. Longitudinal Section through the Armature.

This Eickemeyer winding, in common with the Alteneck and Crompton arrangements, will be observed to be symmetrical, with the attendant advantages. One of the chief, however, among its many claims is the ease with which any damaged coil may be replaced, it being only necessary to undo the joints with the commutator, and remove the outside binding wires, to free the whole. It is economical also in total amount of copper used, and in labour of construction—after the coils are made, that is, as forming up the individual coils in the mould must doubtless take time. The absence of joints, however, especially in the case of large currents, remains one of its chief distinguishing characteristics.

As, both in connection with this latter and the previous windings we have described, we have alluded to the inside or outside union with the commutator, we may, perhaps, with advantage at this juncture also call attention incidentally to a result following on either of these two arrangements. In the Edison (Figs. 9 and 10) and the Hopkinson methods, as illustrated, and the Eickemeyer for low currents, this union is *interior*. In the Crompton and "Westminster" dynamos, and also the modified Eickemeyer for large currents, this union will be observed to be *exterior*. In the former case, and considering any one coupling of whatever form that unites two opposite bar ends, the connection with the commutator is taken off from the *middle* of such coupling, half-way between the bar ends. In the latter, the connection is made at the *end* of a coupling at its junction with a parallel bar. It will thus be seen that with the interior union, a plane through the axis of the commutator and one of its segments will be approximately at right angles to the planes of the coils to which such segment is connected. In the latter case, a plane through the commutator and such segments would be approximately coincident with the planes of its two coils, lying, in fact, between them. Now, in practice, and taking the case of a horizontal field, with pole pieces right and left, the polarity of the armature is brought by the much superior strength of the field to be nearly horizontal likewise: hence the plane of commutation comes about vertical. Thus, consequently, with exterior connections to the commutator, and assuming a horizontal field, the brushes will be top and bottom; while with interior connections, and a plane through the commutator axis and connected segment perpendicular to the plane of commutation, they will come at the sides of the commutator, right and left. When, however, the field is not so strong in proportion to that of the armature as above indicated, or when from any other cause the plane of commutation becomes oblique, the brushes will follow suit in both cases, and touch on the ends of an oblique diameter. It is to be noted, however, in the case of Edison's early end-winding (Fig. 8), that the connection, though *interior*, is yet taken off the *end* of a cross connector, the current running to or from the centre along a radial plate, hence here the brushes would be top and bottom.

*(To be continued.)*

## MEETINGS OF SCIENTIFIC SOCIETIES, &c.

**MONDAY, December 8th.**

SOCIETY OF ARTS.

*8 p.m.* Cantor Lecture I. 3. "Gaseous Illuminants," by Prof. VIVIAN B. LEWES.

THE ELECTRO HARMONIC SOCIETY.

*8 p.m.* Amateur Concert (Ladies' Night), at St. James' Hall Restaurant.

**TUESDAY, December 9th.**

INSTITUTION OF CIVIL ENGINEERS.

*8. p.m.* Ordinary Meeting. Paper to be read: "The New Chittravati Bridge, Madras Railway," by E. W. STONEY, M.E., M.I.C.E. To be followed by a discussion which will include the paper on "The Lansdowne Bridge over the Indus at Sukkur," by F. E. ROBERTSON, M.I.C.E., read at the last Meeting.

ROYAL VICTORIA HALL.

*8.30 p.m.* Lecture: "What we get from Coal Tar," by Dr. FOSTER MORLEY.

**WEDNESDAY, December 10th.**

SOCIETY OF ARTS.

*8 p.m.* Ordinary Meeting. Paper to be read: "Electric Lighting Progress in London." By F. BAILEY.

**THURSDAY, December 11th.**

INSTITUTION OF ELECTRICAL ENGINEERS.

*8 p m.* Annual General Meeting. Election of Council and Officers for 1891. Papers to be further discussed: "The Efficiency of Secondary Cells," "On the Chemistry of Secondary Cells," by Prof. W. E. AYRTON, F.R.S., C. G. LAMB, B.Sc., and E. W. SMITH.

**FRIDAY, December 12th.**

PHYSICAL SOCIETY.

*5 p.m.* Papers to be read: "Some Experiments with Selenium Cells," by SHELFORD BIDWELL, F.R.S.; "Note on Electrolysis," by JAMES SWINBURNE; and "Alternating Current Condensers," by JAMES SWINBURNE.

Cheques and Money Orders should be made payable to "*THE ELECTRICIAN*" Printing and Publishing Company, Limited, and be crossed "Coutts and Co." All other letters to be addressed to the Editor.*

*All letters intended for insertion in "*THE ELECTRICIAN,*" or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever will be taken of anonymous communications.*

"THE ELECTRICIAN" *is published every Friday morning, in time for the morning mails. Subscribers should receive their copies by the first post on Friday morning.*

"THE ELECTRICIAN" *is on sale at the railway bookstalls throughout the Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices as above.*

*New Volumes of* "THE ELECTRICIAN" *commence in May and November.*

## SUBSCRIPTION RATES

The rates for Subscriptions to "THE ELECTRICIAN" are as follows:—

| | 3 months. s. d. | 6 months. s. d. | 12 months. s. d. |
|---|---|---|---|
| For the United Kingdom | 5 0 | 10 0 | 19 6 |
| For Foreign Parts and Colonies:— Within Postal Union | 6 6 | 12 6 | 24 0 |
| Aden Borneo, Ceylon, China, India, Japan, Java, Labuan, Mozambique, New Caledonia, Persia, Philippine Islands, Siam, Transvaal, and Zanzibar | 7 6 | 14 6 | 28 0 |

## TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has by far the largest circulation of any English Electrical paper, and circulates all over the World.**

*Particulars relating to Advertisements will be promptly forwarded on application to the Offices as above.*

TRADE ADVERTISEMENTS *intended for the current issue must reach the Offices not later than First Post on Thursday morning. Renewals of expiring advertisement orders and alterations to standing adv rtisements should be in the Publisher's hands by Wednesday at latest. No alteration can be made in Wrapper advertisements after Wednesday evening.*

SMALL PREPAID ADVERTISEMENTS *(for Rates see page xvii.) are accepted up to 4 p.m. on Thursday.*

## TECHNICAL PRINTING.

"THE ELECTRICIAN" PRINTING AND PUBLISHING COMPANY (LIMITED) *inform Electricians, Electric Light Engineers, &c., that they make a specialty of Technical Printing, and have a large Staff thoroughly acquainted with Electro-Technology. They can, therefore, promise Accuracy and Despatch in the Printing of Electro-Technical Literature, &c.*

## "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. (Royal 8vo.)

*Early in each year is issued* "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. *The* DIRECTORY *was established in 1883, and the 1890 Edition consisted of about 850 pages of printed matter. The names and addresses of all persons engaged in the Electrical Industries at home and abroad may be relied upon as accurate. Useful Tables and Electrical Formulæ, and information specially compiled for this work are given, together with popularly-written Biographical Notices of the leading Electricians, Electrical Engineers, &c., accompanied in many cases by Portraits.*

*Orders for the 1890 issue should be forwarded* AT ONCE *to the Publishing Offices, Salisbury-court, Fleet-street, London, E.C.*

*The 1891 Edition is now preparing, and New Names, &c., can now be received.*

## ELECTRICAL BOOKS AND PUBLICATIONS.

*All Books, Newspapers, and other publications, dealing with Electrical and kindred subjects, can be ordered direct of* "THE ELECTRICIAN" *Printing and Publishing Company, who are proprietors of the well-known* "ELECTRICIAN" *Series of Standard Electrical Works, and are agents for all the leading publishing houses at home and abroad.*

## LLOYD'S RULES FOR ELECTRIC LIGHTING.

The diversity and unsatisfactory state of the rules relating to electric lighting have recently been discussed both in the daily and in the technical journals. Some correspondents have raised objections to the inconvenience of having to follow a number of regulations imposed by several different authorities. Others, who advocated the general adoption of a certain set of rules, were met by the well-founded complaint that their interpretation was left too much to the whims of an inspector. It appears that yet another set of rules has been put forward, and these, when revised, will no doubt come into force before long. They will not, however, in any way interfere with those to which we have referred, as they apply only to electric light on board ship. It is natural that regulations for this purpose should emanate from Lloyd's, and the prestige of this institution, coupled with the fact that they have for many years successfully exercised their authority in matters of engineering construction, will no doubt give to their electric light rules such an influential character that any propositions from other insurance offices will be unlikely to arise.

We have received a report of the Chief Engineer-surveyor, and of his Assistant on electric lighting, and to this is appended the set of proposed regulations. The authors state that they have consulted the surveyors at the ports where vessels have been fitted, and the electricians who have been engaged on the work; they have also gathered from the large steamship companies their experiences, which, as the outcome of actual difficulties surmounted, are naturally of considerable importance. The dangers are of two kinds: the effect on the compasses and the danger of fire. The authors of the report state that "whatever type be adopted, the dynamo comprises, when working, a very powerful magnetic field, with one or more pairs of poles," which "not only exert a directive influence themselves on any compasses near them, but also induce magnetism in masses of iron near them, which in turn affects the compasses." They assume that "it is im-

Digitized by Google

possible to annul the magnetic effect, and all that can be done is to locate the dynamos and compasses as far apart as possible." The researches of these gentlemen have evidently failed to acqnaint them with the so-called ironclad dynamos, although we do not consider that the advantages offered by a complete absence of any external field are of any more importance in connection with the effect on compasses than with the efficiency of the dynamo as a generator. This question, together with the effect of the conductors carrying the current, was discussed somewhat briefly by Sir W. THOMSON, at a meeting of the Institution of Electrical Engineers in May last year, and he then pointed out that the stray field of a modern dynamo is much less than that of the earlier machines. The tendency to make long armatures with plenty of pole-face will materially reduce the leakage at a distance, but any attempts to make cheap or light dynamos by forcing the strength of their fields will have an opposite effect. The inverted arrangement which Mr. WILLANS advocates should be one of the best as regards the effect on a compass, not only because the poles are turned downwards, but because they are buried within the cast iron bedplate.

Although the builder of an inverted dynamo always inquires, if he be mindful of his interests, as to the distance at which his pole pieces will be placed from an iron deck, and the thickness of the deck, the leakage thus produced will only disturb the action of the dynamo if it be so near to the poles that some of the lines of force pass through it rather than through the armature. But a mass of iron at a reasonable distance from the machine will not sensibly lessen its output, though it will gather up all the stray field which might otherwise affect a compass.

We need not here discuss the relative merits of the one-wire and of the two-wire system. Mr. SIEMENS, who so strongly advocates the former, gave little or no reason for his choice in the discussion following the paper to which we have referred. The report alludes to the advantage offered by the double wire system in the reduced action upon the compass. The authors of the report to Lloyd's have grasped the general relations of current, resistance, and volts, and enter into a brief dissertation on them, but it would perhaps have been well if they had sought somewhat higher authority than the electricians who have been engaged on wiring ships. "It is found," they say, "that with wires of the same material, carrying the same current, the rise of temperature is inversely proportional to the square of their sectional areas." The heat generated is proportional to this, but the facilities for its escape, whether into the surrounding air, or into wooden casing, depends upon its surface, and therefore on its diameter; the temperature is then proportional to the square root of the cube of the diameter, as shown theoretically by Prof. FORBES and from experiment by Mr. KENNELLY. In describing compound dynamos and their engines, it is suggested that any variation of speed owing to want of sensitiveness in the governor will necessarily affect the volts, and the stipulation is recommended that the variation in speed should not exceed 5 per cent. With such a variation (and a governor cannot be expected to do more on board ship) the dynamo should be overcompounded; and if overcompounded there is no need to restrict the engine-maker to 5 per cent. if he can make a more efficient governor with a greater range. The report concludes with an allusion to Mr. ANDREWS' concentric system of wiring, and observes that this is practically a single wire system. Some such method is probably the best for ship work, if the return joints are really carefully made, and not screwed, or clamped, or soldered to the nearest piece of metal that happens to be in contact with the skin of the ship. One of the greatest evils of the single wire system is the temptation to make a cheap and easy contact for the return.

The report is followed by "suggested regulations," which are on the whole well drawn up. Some rules, however, seem to be copied from one set into another with little but their hackneyed habitude to excuse them. EDMUND SPENSER'S remarks on the Irish laws three hundred years ago may be applied to some of these wiring rules. "The statutes. . . are not manie. . . and yet of those fewe there are sondrie impertinent and unnecessarie: the which perhappes though at the tyme of the makinge of theme were very needeful, yet nowe through chainge of tyme are cleane antiquated and altogether idle." Such a statute is that which enacts that the copper must be of "a conductivity of at least 98 per cent. that of pure copper." The original framer of this rule presumably wished to avoid overheating, and, knowing that this depends on the resistance, thought he would make a rule which would keep this down as much as possible. The modern regulation of the Board of Trade which goes straight to the point is the proper one, and the rise of temperature should be specified, together with the maximum drop of volts; if a contractor likes to wire with brass under these conditions, there is no very apparent reason why he should not do so. The Board of Trade has very properly dropped the other ancient law which prohibited a greater current density than one thousand amperes per square inch. A little revision will be necessary before these regulations pass the present stage; and we would venture to suggest that a good many hints may be taken from the article on the electric lighting of a modern man-of-war in our issue of October 3. Cut-outs should be fitted to the circuit, says one of the proposed rules, as near as possible to each of the dynamo terminals, and also to each circuit as near as possible to the switches of these circuits. Since the "tree" system of wiring has generally to be adopted in ship work, with mains, branch mains, and lesser branches, instead of the much more desirable plan of mains and single wires for each lamp, the arrangement of cut-outs must be devised to suit it, and instead of a cut-out to each lamp, at the junction with the main, cut-outs must be placed at the branches, as near the larger conductor as possible, but the switch is not the point at which a cut-our is required, and it is by no means advisible to have one at *each* joint. Such a profusion of cut outs introduces a needless multiplication of contacts and resistances. They should be so arranged that no conductor shall be heated above the Board of Trade limit of 30° Fahr. by the current which is required to melt the fuse between that conductor and the dynamo.

The importance of having the very highest class of work on board ship cannot be over-estimated. Although the vessel be in mid-ocean, the conductors always have an "earth" near them. The ever present damp, aggravated by the hygroscopic nature of sea salt, searches out leaks, and corrodes metal fittings. A fire on board ship, even of a limited character, is fraught with the greatest danger, though a similar outbreak on land might cause but a little unpleasantness.

The difficulties of ship lighting are peculiar, and they are by no means fully apparent even to a contractor who has wired and fitted up half-a-dozen vessels. Nor can the sea-going officer, in whose hands the maintenance of the work is placed, be considered to have a complete knowledge of the whole work. An interchange of experience between these two individuals is greatly to be desired. The Admiralty lighting is neither remarkable for economy or for common sense, but the results are satisfactory; while the illumination of the ocean steamers is too often not only annoying, but dangerous, by reason of unsound and careless work.

## NOTES ON THE CHEMISTRY OF SECONDARY CELLS.*

By Professor W. E. AYRTON, Vice-President; C. G. LAMB, B.Sc., and E. W. SMITH, Associates.

*(Continued from page 105.)*

In order to see how far the resistance of the lead grid would tend to make the current-density in the upper part of the liquid less than in the lower, as well as for the purpose of seeing how large a fraction of the whole resistance of the accumulators was due to the lead lugs and to the connections between the successive pairs of lugs, the following tests were made by three of the students—Messrs. Hobson, Lee, and Montealegre:—

Parts of the lead lugs of some of the accumulators were scraped, and on these clean spots binding screws, which had been themselves filed bright, were tightly screwed (Figs. 7, 8 and 9). The accumulators were allowed to send measured currents, the values of which are given in the following tables, and the

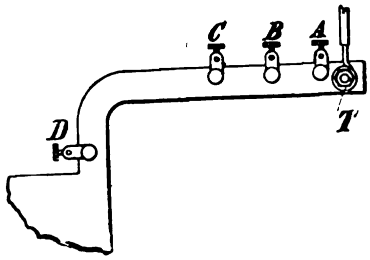

FIG. 7.

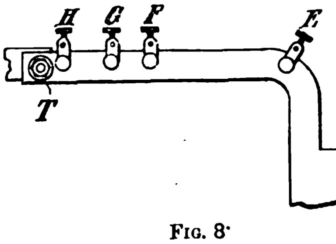

FIG. 8.

potential difference between the pairs of binding screws was carefully measured with a sensitive reflecting voltmeter. The resistance of the lugs between the pairs of binding screws is then at once obtained by dividing the potential difference by the current.

| Fig. | Position of binding screws. | State of nut and Screw T. | Length of lug in inches. | Current in amps. | P.D. in volts. | Resistance in ohms. |

| | F and H | ... | 4·0 | 8 | 0·00126 | 0·000160 |
| | G and H | ... | 1·5 | 8 | 0·00049 | 0·000060 |
| | T and H | Dirty ......... | ... | 8 | 0·00021 | 0·000030 |
| | | Clean ......... | ... | 8 | 0·00021 | 0·000030 |
| 9 | K and L | Dirty ......... | ... | 8 | 0·00522 | 0·000650 |
| | T and O | Dirty ......... | ... | 8 | 0·00063 | 0·000080 |
| | | Clean ......... | ... | 8 | 0·00057 | 0·000070 |
| | K and L | Very dirty ... | 13 | 5 | 0·00500 | 0·001000 |
| | T and O | Very dirty ... | ... | 3 | 0·00524 | 0·001750 |
| | | Clean ......... | ... | 10 | 0·00044 | 0·000044 |

From this it appears that the resistance per inch of the lug alone is about 0·000043 ohm; and that the resistance at the contact of two lugs which were tightly screwed together when quite clean, but which have become very dirty from the acid spray falling on them, may be as high as 0·001 ohm, or thirty times the resistance of an inch of the lug itself. The resistance between T and O (Fig. 9) being greater than between K and L, when T was very dirty, is probably explained by the fact that when the wire was screwed under T to test the resistance between T and O (Fig. 9), it was screwed against an exceptionally dirty bit of the lug.

As we have shown in the Edinburgh paper, the mean resistance from positive lug to negative lug of one of these accumulators *complete* is about 0·004 ohm when the contacts between the lugs and the testing wires are made quite clean. Hence it appears that about one-seventh of the whole mean resistance of such an accumulator is caused by the resistance of the lead lugs themselves; and that the resistance of such accumulators as we have been experimenting with can, when joined up in series, be increased by 25 per cent. if the contacts be allowed to become dirty by the acid spray falling on them, even although they remain all tightly screwed up.

Since these tests were made we have had all the accumulators disconnected, the contacts carefully cleaned and tightly screwed up, and the nuts and screws then coated with hot paraffin wax.

The coarsely divided paraffined cork which is sold by Messrs. Drake and Gorham for floating on the tops of accumulators to filter the hydrogen gas from sulphuric acid spray, was most successful in stopping the acid fumes from escaping into the room when we first obtained it. As, however, the cork became thoroughly wetted with the liquid, its filtering property was much diminished. It appears to us that there still remains the need for a really good spray-arrester.

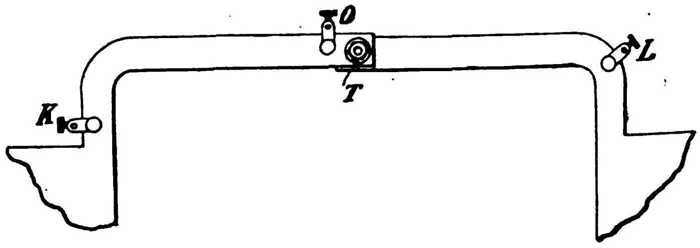

FIG. 9.

### IV.—ANALYSIS OF PLUGS.

The following is the report of the analyses of the plugs removed at different stages of the charging and discharging, which Mr. Robertson has been so kind as to prepare for us:—

*Report by G. H. Robertson on Analyses made in the Chemical Department of the Central Institution of Plugs from an E.P.S. Cell.*

*October 16th, 1890.*

Preparation of the samples for analysis:—

The positive samples were taken separately, washed on to filters, and thoroughly freed from acid. In every case the samples from the bottom were harder to wash than the others, and the residues were dried for some hours at about 120° C.

The samples were now ground up fine in an agate mortar, and the splinters of wood and glass removed as far as possible. The approximate weights for analysis were now taken and re-dried on watch glasses at about 140° C.

At first the substance for analysis was dissolved in a porcelain dish, and the insoluble residue of sulphate was filtered off, with the intention of determining the amount of sulphate by the ammonium acetate method; but owing to the small amount of material available, and the error introduced by the solubility of lead sulphate in the nitric acid used to dissolve the sample, the attempt to determine both the peroxide and the sulphate was abandoned, and the samples were used to determine the peroxide only as accurately as possible. This course was justified by the fact that very careful qualitative experiments showed that nothing but peroxide and sulphate was present in the plugs.

The method employed to determine the peroxide was the ammonium oxalate and permanganate method described in Sutton's "Volumetric Analysis," as in previous analyses it had been found very sensitive; and the solutions were checked about every two days against pure lead peroxide, and each day the solutions were run against each other, but they were not found to alter practically in the time they lasted. The first lot of ammonium oxalate was standardised against permanganate, which had been very accurately standardised against iron, and by the nitrometer method.

| D′ | Top ... 41·8, 44·01, 43·9 | 43·2 | 41·4 | ↓ ↑ | 14 37 | 0·6 | 1·9 | 1·175 |
| | Middle 42·70, 42·92 | 42·81 | | | | | | |
| | Bottom 37·9, 38·6 | 38·25 | | | | | | |
| | | | | 5·4 3 26 | | | | |
| E′ | Mixed 36·6, 36·7, 34·8 | 36·00 | | ↓ | 18 3 | Zero indefinite on re-making circuit. | E.M.F. | 1·172 |

Using this solution, "pure" lead peroxide, as purchased, and which afforded a slight white residue like silica, contained 97·3 per cent. as the mean of a large number of analyses made with different weights; and any subsequent solution which gave the percentage between 97 2 and 97·5, inclusive, was taken as correct. It will be noticed that D and A′ gave practically the same percentage as the sample of pure lead peroxide.

The residues from the samples containing the highest percentage of peroxide of lead were white, those from the samples containing the smaller percentage were brownish-white; and it was noticed that if the larger grains were crushed under the end of a glass rod they had a dark centre of peroxide, which at once dissolved, leaving a slight yellowish-white insoluble ring. By grinding the sample very fine in the mortar, so as to break up the capsules of sulphate more thoroughly, the residue was got lighter in colour; and using a flask to boil the substance in, the residue becomes perfectly white; but this yellowish-brown tinge to the sulphate does not seem to be due to any appreciable quantity of undissolved peroxide, as practically identical percentages were obtained with pure white and yellowish residues. Dark residues gave low results.

In the case of the very hard plugs, there was some error from the glass and wood, which could not be picked out altogether, though the samples were picked over very carefully (*cf.* D′, E′).

In the case of the negative plates, the sulphate was in such a loose and powdery condition that it fell off and adhered to the insides of the bottles used for receiving the plugs in, and it was quite impossible to obtain representative samples for quantitative analysis; so qualitative tests had to be made, which, in the case of charge, showed nothing but sulphate of lead and lead, the sulphate decreasing during charge until at D there was practically nothing but pure lead.

During discharge the sulphate increased; at C′ there was a doubtful indication of peroxide of lead, and at D′ and E′ there was decided evidence of peroxide. After a few days the plugs were white all over, and there was no difference in appearance between the front and back. The water had no acid reaction.

For the sake of comparison, the percentage of $PbO_2$ at A in the following table is taken as 47·9 as at C′.

The calculations refer to the mean values of $PbO_2$, and the values of potential difference before breaking circuit.

| | Interval. | Increase per Hour in Percentage $PbO_2$. | Percentage Increase in P.D. in Interval. | Percentage Increase in $PbO_2$ in Interval. |
|---|---|---|---|---|
| CHARGE. | A to B | 3·0 | 3·1 | 27·6 |
| | B to C | 4·8 | 1·6 | 8·8 |
| | C to D | 3·8 | 7·4 | 10·8 |
| | **Interval.** | **Decrease per Hour in Percentage $PbO_2$.** | **Percentage Decrease in P.D in Interval.** | **Percentage Decrease in $PbO_2$ in Interval.** |
| DISCHARGE. | A′ to B′ | 4·3 | 2·1 | 31·7 |
| | B′ to C′ | 3·6 | 5·4 | 15·3 |
| | C′ to D′ | 2·6 | 67·4 | 6·5 |
| | D′ to E′ | 1·6 | 100·0 | 5·4 |

The screening influence of lead sulphate is clearly brought out in this table. Between A and B the surface film and the coatings on the partially reduced granules of $PbO_2$ are got rid of; then between B and C the pure lead sulphate is attacked; and finally, between C and D, with the removal of the last traces we get a very rapid rise in volts potential difference.

It will be observed that:—

(*a.*) The particles of the peroxide very soon get coated in the discharge with a layer of lead sulphate which protects the peroxide from further action, as shown by the examination of the dark-coloured residues which contained peroxide, and which were rendered very hard to dissolve by the coating of sulphate.

(*b.*) The analysis also shows what a large proportion of active material is still remaining at the end of the discharge. This has been remarked on by many experimenters.

(*c.*) The loose powdery surface of the positive plate seems to be thoroughly converted into lead sulphate. C and B′ dissolve readily, leaving pure white residues.

(*d.*) When the peroxide in the surface of the plate falls to about 31 per cent. the cell loses its E.M.F. very rapidly, owing to the inactive layer of sulphate impeding the action of the sulphuric acid on the active material behind it, and also to the formation of peroxide on the negatives. The diffusivity of the acid is decreasing, and it has to penetrate further into the plate to find active material. When the whole of the paste approaches this composition of 31 per cent. peroxide, the cell loses its E.M.F. entirely.

(*e.*) The action seems to take place most rapidly where the current-density is greatest; the plate gets hard there from sulphate soonest on discharge, and oxidises quickest on charge.

Planté and Messrs. Gladstone and Tribe have both noticed the formation of peroxide of lead on the negative plate during discharge, and pointed out that once it is formed more rapidly than it is reduced, the two plates must rapidly approach electrical equilibrium; that when the circuit is broken local action alone can take place, and this will reduce the peroxide on the negative plate, and on making the circuit again the cell will again give a current; and in this way Messrs. Gladstone and Tribe account for the resuscitating power of the cell, as well as for the rise of E.M.F. on breaking the discharging circuit.

I have to acknowledge the facilities afforded me for seeing the plugs as they were removed, and the care taken to let me have the samples in good condition.

I am also indebted to Professor Armstrong for his invaluable advice and assistance in the execution of the work.

G. H. ROBERTSON.

Digitized by Google

From the mean results of the preceding analysis carried out by Mr. Robertson, we have drawn the curves seen in the lower part of Figs. 1 and 2, and which show the percentage of $Pb\,O_2$ found in the plugs of the positive plate at all stages of the charge and discharge. In the $Pb\,O_2$ curve for charge the first point is obtained from the analysis of the plugs at the end of the normal discharge—that is, when the terminal potential difference had fallen to 1·85 volts, indicated by the point C′ in Fig. 2. The percentage of $Pb\,O_2$ actually found in the positive plugs at the point indicated by A (Fig. 1) does not lie on the $Pb\,O_2$ curve as drawn, but, as already indicated, this arises from the specimens removed from the plugs at experiment A being only scrapings off the surface, and therefore not representing the average constitution of the plugs. On all subsequent occasions when specimens were removed from the plates, whole plugs as already stated were detached. The analysis at the point A (Fig. 1) was, therefore, abnormal, and the percentage of $Pb\,O_2$ obtained for this point, and which is given in the table, is not indicated on the curve.

If the energy given out by the cell be produced by the conversion of $Pb\,O_2$ in the positive plugs, and of Pb in the negative, into lead sulphate, a constant value of the potential difference at the terminals of the cell when a constant current is passing through it ought to correspond with a constant rate of variation of the percentage of $Pb\,O_2$ in the positive plugs; so that for a constant current

$$\text{the terminal potential difference should} \propto \frac{d(Pb\,O_2)}{dt},$$

$t$ representing time. This connection is seen to exist fairly well in the case of the discharge where the slope of the $Pb\,O_2$

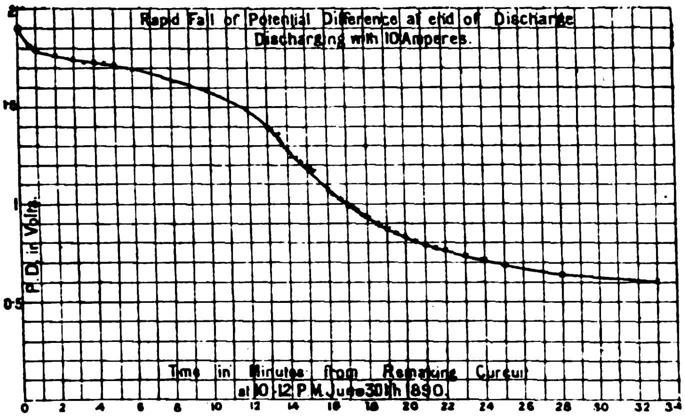

FIG. 10

The date on this curve should be June 10th.

curve is roughly constant as long as the potential difference is constant, and acquires a less inclination to the axis of time when the potential difference is rapidly falling. In the case of the charge, the connection between the value of the potential difference and the slope of the $Pb\,O_2$ curve is not so easily seen; but this arises from the fact that towards the end of the charging there is a rapid rise in the resistance of a cell, and therefore in the potential difference required to send a constant current through it; further, the back E.M.F. steadily increases during charging on account of the polarisation, which grows larger and larger from the continuous evolution of gas at the surface of the plates.

As already explained, the constant discharge-current of 10 amperes was, by the employment of some auxiliary cells, left flowing through the accumulator under test, even when its E.M.F. became very small. Towards the end of the discharge the fall of potential difference at the terminals of the cell under test became extremely rapid, so that, for example, on closing the circuit after the removal of the plugs at D′ (Fig. 2) the potential difference fell from 1·9 to 0·6 volts in 33 minutes, as seen from Fig. 10. This rapid fall is probably due to lead peroxide being formed on the negative plates more rapidly than it could be removed by local action, since the chemical analysis showed decided evidences of lead peroxide on the plugs removed at D′ from the negative plates. At E′ (Fig. 2) the E.M.F. of the accumulator under test became reversed, but rapidly recovered its original direction on stopping the discharge currents, as seen from Fig. 11.

It is a very striking example of the recuperative action of a secondary cell that you can completely discharge it as you think, and then even charge it in the wrong direction, but it will, on being insulated, rapidly recover an E.M.F. in the original direction. Indeed, we were told of a curious case some time back: after the removal of the laboratory, employed for testing ammeters, from one part of a well known London factory to another, it was found that the E.P.S. accumulators always ran down very rapidly whenever an attempt was made to use them, in spite of their having been charged in the intervals. As the E.M.F. was always in the right direction it was supposed that the cells had become partially short-circuited in the removal, and it was not for some time that the true explanation of the refusal of the cells to do their work was discovered. The real fact was that in fitting up the new laboratory the leads from the dynamo to the switch had been reversed, so that the unfortunate cells were charged in the wrong direction every time the dynamo was turned on.

The preceding incident also forcibly illustrates the sort of attention that secondary cells may receive in practice, and shows the necessity for the potential difference and specific gravity being occasionally measured, even in places where the

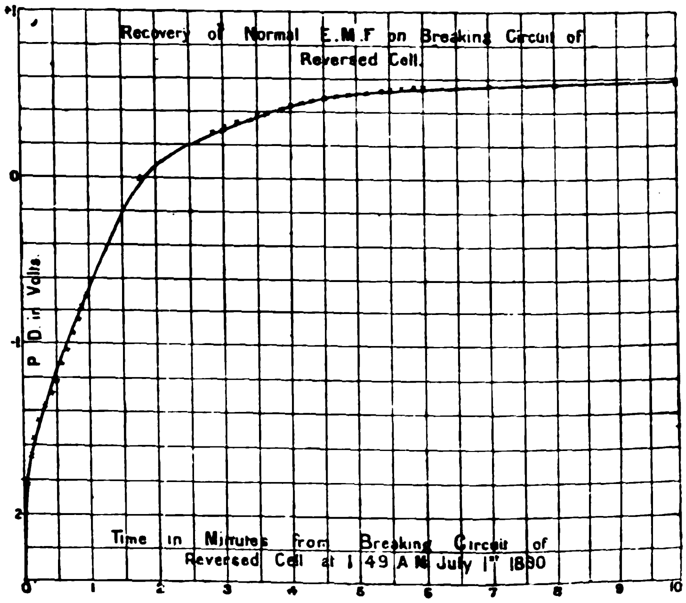

FIG. 11.

study of the behaviour of cells is not the main business of the factory.

One of the great defects of the earlier specimens of the E.P.S. cells lay in the buckling of the plates. Mr. Capito tells us that it was Mr. Collet who noticed that all the plates generally curved in one direction, and who suspected that this arose from the unequal chemical action on the two sides of the last positive plate of the cell. Mr. Collet therefore proposed putting a negative plate at each end of this cell, and this plan—which has been always followed since—of using one more negative than positive plate, has had much to do with removal of the buckling difficulty.

### V.—Effect of Rest on Charged Accumulators.

As the result of a number of tests described in our Edinburgh paper, we found that if E.P.S. accumulators be charged with 9 amperes and discharged with 10 a number of times without intermission, between the potential difference limits of 1·8 and 2·4 volts per cell, until the cells are brought to a perfectly steady "working state," the quantity efficiency is about 97 per cent., and the energy efficiency 87; further, that if the cells be fully charged until the potential difference per cell is 2·4 volts, and then be left perfectly insulated for 16 days, the next discharge between the fixed potential difference limits only gives out about 65 per cent. of the ampere-

hours, and about 57 per cent. of the energy put in before the rest. Further, not merely is energy lost during the rest of an insulated accumulator, but for several subsequent charges and discharges between the same potential difference limits after the rest the storage capacity and the quantity and energy efficiencies are all lower than before the rest.

For the purpose of examining into what took place in an accumulator which was left charged, a small E.P.S. cell was charged until the potential difference was 2·4 volts, and then the positive plates were withdrawn and put into another vessel containing dilute acid of specific gravity 1·2, the negatives being left in the vessel in which they were charged. Both sets of plates were covered up with gutta-percha hoods, the edges of which dipped under the liquid, and to the top of each hood was fitted, gas-tight, a vertical graduated glass tube, closed at the top. The hoods and the glass tubes were first filled with liquid, and the amount of gas that came off from the two sets of plates was measured from day to day by watching the descent of the liquid in the tubes.

No gas was seen to come off from the positive plates, but in the case of the negatives gas came off very slowly at first, then more rapidly, and finally more slowly again. The following table gives a record of the amount of gas that came off from the negative plates, the gas on analysis being found to be hydrogen* :—

*Hydrogen Gas Collected from Charged Negative Plates after Removal of Positive Plates.*

| Date. | Time. H. M. | Cubic centimetres of gas collected. | Time of collecting gas, in hours. |
|---|---|---|---|
| November 15th | 11 45 | 0 | 0 |
| „ 17th | 10 0 | 2 | 46 |
| „ 20th | 12 0 | 52 | 120 |
| „ 21st | 10 0 | 72 | 142 |
| „ 22nd | 10 0 | 87 | 166 |

If the lead of the positive plate be turned into lead sulphate by local action, 87 cubic centimetre of hydrogen liberated corresponds with about 0·81 gramme of lead turned into sulphate. It is clear, then, that the lead of the negative plate is steadily being turned into some oxide or salt, and probably the loss of energy which we observed in the charged cell left insulated for many days was due to this local action at the negative plate. And further, as this action takes place apparently only at the negative plate, it is clear that in the subsequent discharge the cell will appear to be discharged before the positive plate is discharged, and charged up again without reducing all the lead sulphate on the negative plate. The local action at the negative plate while a cell is standing charged has, therefore, for the first few discharges and charges after a long rest, exactly the same effect as if a portion of the negative plate had been bodily removed out of the cell. Hence we see that the peculiarities observed by us in curves 8 to 23 in our Edinburgh paper may be explained by this defective behaviour of the negative plates.

### VI.—Construction and Formation of E.P.S. Plates.

The question arises why the E.P.S. accumulators are so constructed that the plugs in the positive plates contain some 48 per cent. more peroxide of lead than is required to be converted into sulphate in the normal discharge. Two explanations suggest themselves. One is, that since the granules of lead peroxide begin, as we find, to be coated with a protecting coating of sulphate early in the discharge, it is impossible, with the present form of plate, for the interior of each granule of lead peroxide to be converted into sulphate, and therefore it is necessary to employ nearly twice as much lead peroxide as is actually needed for the chemical action. Another reason is the fear of the positive plate crumbling to pieces if it be completely formed; and this reason Mr. Capito, who was formerly in the employ of the Electrical Power Storage Company, thinks, on the whole, is the more important.

* Since the preparation of this paper we have noticed that Dr. Gladstone and Mr. Hibbert, in their paper communicated this summer to the Physical Society, have also observed that hydrogen comes off from a charged negative plate of a secondary cell when left idle.

In the construction of the original Faure accumulators, as well as of the early E.P.S. cells, both the positive and the negative plates were pasted with red lead ($Pb_3O_4$), and formed together for a period of some 50 hours. Later on litharge ($PbO$) was used to coat the negative plate, red lead being used only for the positive one, and the plates were formed separately, the negative being much more formed at the works than the positive. Some time ago I was informed by a very competent authority that the following is the modern process of *forming* employed by the Electrical Power Storage Company:—

*Positive plates.*—8⅞in. by 7⅞in. by ¼in. Two amperes per plate, or 0·028 ampere per square inch, sent for 18 hours.

*Negative Plates.*—9in. by 9⅝in. by $\frac{3}{16}$in. One and a-half to two amperes per plate, *i.e.*, 0·017 to 0.023 amperes per square inch, for 120 hours.

The actual time of forming either set of plates depends greatly on the length of stoppages during the formation. This is especially the case with the negative plates, therefore they endeavour to form the negatives for the 120 hours without any stoppage of the current. On the receipt of a cell from the Electrical Construction Corporation, the purchaser is requested to form it for 40 hours more with the ordinary charging current used in working, which is at the rate of 0·026 ampere per square inch.

Mr. Capito tells us that, when he was at Millwall, such periods of formation as 120 hours were not used; and he thinks that this may be due to the fact that formerly the plates were not dried after pasting and before formation, as they are at present. This drying hardens the plates and produces a better cell; but he thinks that, as the paste is itself mixed with sulphuric acid, there is probably some sulphating of the negative plates during drying, and that several hours in the subsequent formation are probably spent in reducing this sulphate.

The reason, we understand, for the manufacturers only forming the positive plates for 18 hours, and leaving the purchaser to form them for the remaining 40 hours, is that if positive plates be *well formed* and then dried for carriage, the plugs become loose, which is not the case if the positive plates be only slightly formed before drying.

We were interested in learning from Mr. Capito whether, while superintending the manufacture of many thousands of accumulator plates, he had ever tried pasting the positive with lead peroxide ($PbO_2$) in order to avoid the necessity of having to form this salt electrically out of the red lead with which the positive plates are usually pasted. This idea of applying a paste of lead peroxide directly to the positive plate, he told us, he had tried, but that the method turned out a failure, from the impossibility of getting the lead peroxide paste to stick on to the grid even when some red lead was mixed with the lead peroxide. He also mentioned a very interesting fact—that whereas a paste of red lead mixed with dilute sulphuric acid of density 1·1 gives an adherent deposit on formation, on the contrary, a powdery deposit is produced if the density of the liquid used in making the red lead paste be 1·2. We understand the process that has shown itself the best is to use dilute sulphuric acid of density 1·1 for mixing the red lead paste, and dilute acid of 1·2 for mixing the litharge paste for the negative plates.

**Royal Society.**—At the anniversary meeting of the Royal Society, held on Monday last, the Rumford Medal was presented to Professor Heinrich Hertz, for his work in electro-magnetic radiation, and a Royal Medal to Dr. J. Hopkinson, for his researches in magnetism and electricity. The Society elected the officers and council for the ensuing year, and Sir William Thomson was chosen president in succession to Sir G. Stokes. In the evening Sir W. Thomson took the chair, as president, at the dinner of the Society at the Hôtel Métropole.

## THE WATER-POWER OF THE FALLS OF NIAGARA.*

For many years it has been a matter of frequent comment, that at Niagara there existed an enormous water-power not utilised, and the feasibility of usefully applying a portion of the power of the cataract has been discussed for many years by the scientists and manufacturers of America. The illustration (Fig. 1) will give an idea of the inexhaustible source of the power, unaffected by floods or droughts.

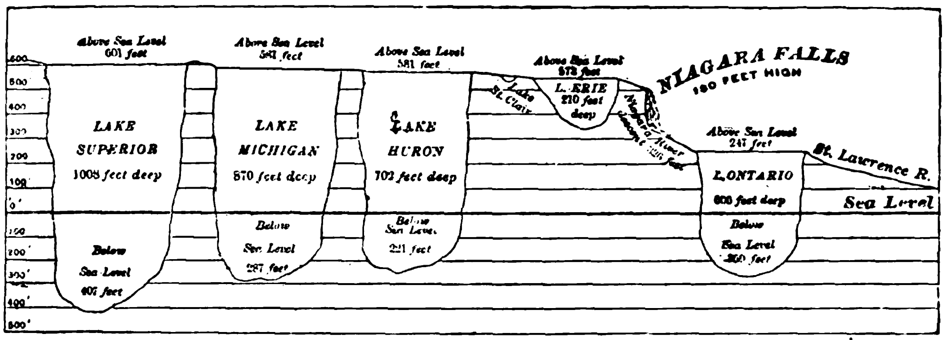

Fig. 1.—Depths and Levels of the Great Lakes supplying the Niagara Falls.

In March, 1886, the Niagara Falls Power Company was incorporated by a special act of the Legislature of the State of New York, for the purpose of constructing, maintaining, and operating the hydraulic tunnel, and for furnishing power for manufacturing purposes. The company has purchased lands extending two miles along the shore of the Niagara river adjacent to the hydraulic tunnel, which have been laid out for lots, streets, mill races, wharves and railway sidings for the purpose of forming a town composed wholly of mills, factories, and workshops. The company has also purchased an adjoining tract of one thousand acres, which has been laid out in streets and lots for homes for workmen employed. This association of prominent business men at Niagara Falls was organised for the further development of the water-power at Niagara. For this purpose, from the water level below the Falls, a subterranean tunnel will be constructed of horse-shoe shape, having capacity equal to a circle 25ft. in diameter, extending through the solid rock, to the upper river at a point about one mile above the Falls. From this point the tunnel continues parallel with the shore of the river one and one-half miles, at an average depth of 160ft. below ground, and about 400ft. distant from the navigable waters of the river, with which it is connected by means of surface conduits or canals, through which the water from the river enters, and is drawn through the shafts and wheel-pits into the great tunnel below, which forms an immense tail race for all of the mills, factories, and workshops. The plans adopted will develop 120,000 horse-power.

For convenience of construction, the work will be divided into three sections. The plan of the first section, upon which work is now begun, is shown in Fig. 2. The water falls upon turbine wheels, which will be put in by the company in a number of the pits, and the power developed thereby will be brought to the surface, from which point it will be delivered to the numerous mills and factories, or transmitted by cable, pneumatic tube, or electricity to adjacent lands, as the customers may desire. The company will also lease power to customers wishing to excavate their own wheel-pits, and put in their own water-wheels and connections.

For the construction of this great work a contract has been made, and under it operations have been commenced by the Cataract Construction Company upon the building of the tunnel and the shafts, raceways, and works to complete the undertaking.

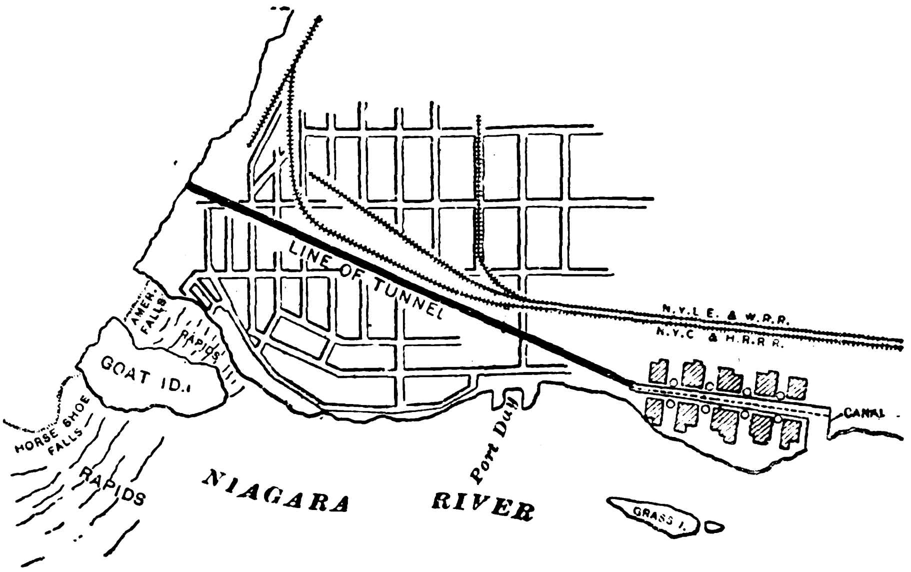

Fig. 2.—Plan of the First Portion of the Hydraulic Tunnel.

* From an illustrated Pamphlet issued by the Niagara Falls Power Co.

## THE PROTECTION OF THE ELECTRICAL INDUSTRY IN FRANCE.

A Committee of the Chambre Syndicale des Industries Électriques, appointed to investigate the question of the degree of protection required by the electrical industry in France, has just published an instructive report containing recommendations which are of considerable importance in view of the probability of their adoption by the Legislature when the treaties of commerce expire in February, 1892.

The report commences by pointing out that on the occasion of the last renewal of commercial treaties in 1881, the electrical industry was practically non-existent. Electric bells and fire alarms were the only apparatus specifically referred to, and these were subject to a duty of 15fr. per 100 kilogrammes, all other electrical apparatus being ranged under the head of

Digitized by Google

"Optical, observational, calculating, and mathematical instruments." In 1886, however, this "fantastic classification" was reformed, and the words dynamos, arc lamps, incandescent lamps, and accumulators were introduced into the customs' list and appropriate duties were levied.

"Such is the situation," the report goes on to say, "in which our industry has been placed since 1886. It corresponds neither to that of our competitors in the adjacent countries, nor to the exigencies of French labour. It leaves us completely disarmed in the face of foreign competition, and the Chambre Syndicale owes it to itself, and to the important interests which it represents, to agitate in the proper quarters, so that this state of affairs may be modified in 1892, when the commercial treaties which at present tie us will expire. Our industry is no longer a negligible quantity. It employs nearly 4,000 hands, and produces annually goods to the value of more than 30,000,000fr. For the past three or four years the electrical industry has been obliged to maintain against foreign firms a struggle which daily becomes more severe. These competitors, thanks to their protective tariffs and favourable economic conditions, have obtained a footing in our country which must be regarded with anxiety, unless the future is to be assured to us by a recasting in 1892 of the existing duties."

The report then proceeds to argue that a "compensatory," not a "protective" tariff is what is wanted, and figures are quoted showing the comparative cheapness of labour and materials in adjacent countries, and the necessity, therefore, for the imposition of import duties to maintain the equilibrium. "There is an universally held prejudice that to protect a new industry by import duties is equivalent to condemning it to stagnation, and, by reason of the suppression of foreign competition, to destroy the inevitable necessity for progress. Nothing is more specious, yet nothing can be more fatal. On the contrary, the manufacturer protected by a reasonable duty and consequently assured of a fair profit, is stimulated to improve his products in order to compete with native firms, and to impose his goods on the foreigner. The profits on home sales then suffice to cover general expenses, and he is therefore in a position to compete abroad, since any price that he obtains over and above the mere cost of labour and material is clear profit. This, in fact, is the policy of our German, Swiss, and Belgian neighbours." Figures are then brought forward to show that labour is from 40 to 100 per cent. cheaper across the French frontier, and that the cost of materials is about 10 per cent. less. The exact amount of the duties levied by adjacent countries on electrical goods is, it seems, difficult to determine exactly. The conclusion drawn from the result of all these investigations is, that the imposition of *ad valorem* duties are necessary to "defend our imperilled industry against invasion."

The committee then go *seriatim* through the different electrical articles manufactured in France, assigning to each the protective duty which they deem to be necessary.

*Telegraphic Apparatus.*—The existing duties, it seems, require no amendment, telegraphic apparatus being only purchased by Government and by the great railway companies. In the case of the former, the law prohibits the purchase of foreign apparatus, and the railway companies have always made it a point of honour to follow suit.

*Telephonic Apparatus.*—No alteration required, the State being now the only purchaser, and "French apparatus being far better than foreign."

*Measuring Instruments.*—No alteration required, since accuracy is of more importance than cheapness in this class of apparatus. Moreover, from time immemorial all States have allowed physical instruments to go duty free in the interest of scientific progress, and "France could not be the first country to give up a custom conceived in such a liberal spirit." The Committee, however, cast longing eyes on voltmeters and ammeters, but relinquish the idea of imposing a tax, owing to the difficulty of definition,

*Voltaic Batteries.*—The present duty is vague, but owing mainly to the fact that the parts of a voltaic battery are generally imported separately, no alteration is proposed.

*Electric Bells and Domestic Accessories.*—For various good and sufficient reasons, this branch of the French electrical industry can, so it appears, hold its own in spite of the fact that the present duty of 2 per cent. is "absolutely derisory."

*Electric Light Apparatus.*—This branch of the industry is, according to the report, in a very parlous state. Belgium, Switzerland, and even the United States, compete in respect of dynamos. Germany inundates the country with cheap arc and incandescent lamps, while Belgium begins to rival England and Germany in its electric light cable imports.

*Dynamos.*—Analysing the cost of production of a 45 horse-power Gramme machine, the committee find that material costs 1,600fr. and labour 600fr. in France, while across the frontier the figures are respectively about 1,440fr. and 330fr.; that is to say, a 45 horse-power Gramme machine, which can be turned out for about 1,770fr. across the French frontier, cannot be turned out for less than 2,200fr. in Paris, or sold at a fair profit for less than 3,500fr. Similar analyses lead to similar results, and the committee consequently recommend a "compensatory" *ad valorem* duty of 10 per cent. Dynamos weighing less than 10 kilogrammes are, however, to be allowed in duty free, being physical apparatus.

*Arc Lamps.*—The present duty amounts to 1·33 per cent. The average cost of an arc lamp made in France may be taken at 95fr., viz., 35fr. for material and 60fr. for labour, and the cost of production of a similar article abroad is worked out at 76fr. 50c., or 18fr. 50c. less. Since, therefore, an arc lamp is sold at about 150fr., the difference in cost of production amounts to 12 per cent. of its selling value. The French arc-lamp makers are, however, magnanimous; they only want a 10 per cent. duty.

*Incandescent Lamps.*—These lamps, which used to be sold in France at 6fr., can now be bought, the report states, for from 1·8fr. to 2·25fr. Such prices, we are assured, render profit impossible to French manufacturers. In Germany, where the manufacturers are protected by a 12 per cent. duty, and where the consumption is considerable, they are able to export lamps at a profit, so long as they fetch more than 1fr. In Paris the cost of production of an incandescent lamp is 1·4fr., and, taking other items into consideration it cannot be sold at a profit for less than 1·85fr. Taking, however, the present average selling price as 2fr., and allowing ·4fr. for the difference between the cost of German and French labour, a "compensatory" duty of 20 per cent. is deduced, the present duty being at the rate of ·15 per cent. The French Edison Company thought a 25 per cent. duty desirable, but the committee feel unable to recommend anything higher than 20 per cent.

*Arc Light Carbons.*—"The lamentations of the arc light carbon-makers are," the report states, "more sharp even than those of the lamp-makers. It is incontrovertible that German competition has rendered the fight impossible." The cost of production of a 10mm. carbon in France is placed by the committee at 35 centimes, while German carbons can be *bought* in Paris for 28 centimes. Logically applying the "compensatory" principle would mean the imposition of 30 per cent. duty, a duty, indeed, which is "energetically called for" by the carbon manufacturers. Again, however, the Committee are unable to recommend such a prohibitory tax, and propose a 20 per cent. *ad valorem* duty. Carbons from Germany, being classed as lampblack, are admitted into France practically duty free, paying only a tax of 1·25frs. per 100 kilogrammes. The German tax, on the other hand, is 37·5frs. per 100 kilogrammes, or about 15 per cent. *ad valorem.*

*Accumulators.*—Accumulators, being classed as sheet lead, pay a duty of 3frs. per 100 kilogrammes, *i.e.*, about 1·5 per cent. *ad valorem.* "In spite of the insignificance of this tax, foreign competitors have not, so far, succeeded, except by virtue of the superiority of their products . . . It would seem, therefore, as if our manufacturers are able largely to hold their own. . . . Nevertheless, the arguments which have been brought forward elsewhere with regard to the difference in the cost of labour and material in France and Belgium (the important manufacturing centre) prove the equity of imposing a tax of ·24 per kilogramme, or 10 per cent. *ad valorem*, in order to maintain

Digitized by Google

an equal balance between this apparatus and the other electric lighting appliances which we desire to protect."

*Electric Cables.*—The cost of the insulating material being so greatly in excess of any other item, and its cost being much the same in all European countries, the cost of labour becomes comparatively unimportant; as, however, this latter item amounts in France to between 8 and 10 per cent. of the selling price, and only to between 4 and 5 per cent. in Germany, a 5 per cent. *ad valorem* duty is proposed. Belgium imposes at present a 10 per cent. duty on French cables, and France a 2 or 3 per cent. duty on Belgian cables.

*Detached Pieces.*—Coming finally to the consideration of possible fraud on the part of the heavily taxed foreign competitor, the Committee propose to prevent the "tariff being turned" by the imposition of a double duty on sundry detached articles.

*Conclusion.*—This remarkable document concludes as follows:—"To resume, gentlemen, your Committee propose, after an exhaustive investigation of the electrical industrial situation, that the following *projet de taxation* should be adopted, and inserted in the general Customs list which will be promulgated on February 1, 1892, and ask you to empower your Committee to urge with energetic perseverance its acceptance by the authorities."

List of Proposed Duties.

## THE ELECTRICAL TREATMENT OF SEWAGE.*

BY W. WEBSTER, F.C.S.

In the early days of the process experiments were made with electrodes of carbon and platinum, but the high cost of the latter and the disintegration of the former in the presence of the nascent elements compelled their abandonment in favour of iron. This alteration brought other chemical reactions into play, and though the precise mechanism of the change was still somewhat obscure, a hypochlorite of iron appeared to be formed at the expense of the anode and the chlorides naturally present in sewage. The progress of the purification was attended with the production of ferrous hydrate and ferrous carbonate, the former of which acted as a precipitant. On the passage of the current the sludge began to separate as a flocculent precipitate. When this was done on a laboratory scale, the flocculent matter rose, being full of hydrogen bubbles, but in practice it went to the bottom. The method now adopted consisted essentially in passing the sewage through a brick channel contained a large number of cast-iron electrodes connected in parallel, The cast-iron plates were from ½in. to 1in. thick, and 6ft. long, and 25 pairs were connected in series, the pressure between each pair being about 1·8 volts. The plates were placed in a shoot 18in. deep, 2ft. wide, and 200ft. long. Favourable reports had been received from various well-known experts, one of whom—Sir Henry Roscoe—had had entire control of the experimental work for about a month. He found from 70 to 80 per cent. of the organic matter precipitated, as the following figures, taken at hazard from his analysis, indicate:

| | Oxygen absorbed. | Albumenoid ammonia. |
|---|---|---|
| | (Parts per 100,000.) | |
| Raw sewage | 5·64 | 0·87 |
| Unfiltered effluent | 1·92 | 0·45 |
| Raw sewage | 5·49 | 1·12 |
| Effluent | 1·48 | 0·14 |

About 20,000 gallons were treated, samples being taken every five minutes. The nature of the effluent was most satisfactory; no tendency to subsequent putrefaction was detected even under severe conditions of testing. There was a small quantity of red hydrate of iron in suspension, giving a reddish colour to the effluent; this would be an advantage when turned into a stream rather than otherwise, but it might very easily be removed by filtering through 6in. of sand if required. Besides this experimental work which had been on London sewage, the process was being tried at Salford, the sewage from that town and Pendleton being treated. Efficient purification was of particular importance here, as the effluent would pass into the Manchester Ship Canal, and must be of reasonable purity.

The quantity to be dealt with was 10,000,000 gallons per 24 hours, and for this it was calculated about 400 indicated horse-power would be requisite. The plant would consist of three boilers of 200 indicated horse-power, any two of which would suffice to do the work, and four engines, any three of which would be similarly adequate.

In the estimate of working expenses no commercial value was credited to the sludge, though after being dried and ignited it might serve as a filtering material in the event of a clear effluent being required. The current required per gallon was ·37 ampere hour, which was equivalent to 37 horse-power per million gallons. The annual cost of running the process was reckoned at £2,500, with an additional sum of £2,500 for the deterioration of 5,000 tons of iron electrodes. If a clear effluent were necessary, a further charge of £1,200 to £1,500 would have to be met.

* Abstract of a Paper read before the London Section of the Society of Cemical Industry, on Monday, December 1st. In the absence of Mr. W bster the Paper was read by Mr. Worth.

### DISCUSSION.

Mr. BISCHOFF spoke of the work of earlier experimenters on the resistance of the living organisms commonly present in sewage to the effects of electrolysis. The outcome of their investigations was that a considerable voltage and a comparatively high temperature were necessary for complete sterilisation. He doubted whether the Webster process would succeed in this particular respect.

Mr. SILLER regretted the apparent indifference of those interested in this process to the possible value of sludge obtained by various methods of purification, and instanced the success of the A. B. C. process at Kingston, where some 10,000 tons of sludge had been sold in the course of twenty-five years for £34,000, the harmlessness of the effluent to fish life must also be considered.

Mr. BIRCH joined issue with the last speaker on the question of the value of the sludge, holding that that derived from the Webster process should be at least as valuable as the A. B. C. product, there being no addition of clay, &c., and inquired the cost per head for the complete treatment of ordinary town sewage, both as proposed, and also for a higher degree of purification than had been hitherto attained.

Mr. CROSS dealt particularly with the scientific aspect of the process, asking for further information as to the reactions that took place during electrolysis. In the *precis* of the experts' reports that had been submitted to the meeting, nothing was said as to the degree of aëration of the effluent. He was of opinion that most, if not all, the dissolved oxygen —so potent a factor in water purification—was consumed to convert ferrous salts into the ferric state.

Mr. NEWLANDS remarked that electrical processes were apt to be viewed with a little suspicion if applied to products and materials having apparently little connection therewith. He could remember the commotion created by the application of an electrical process to the purification of a substance with which he had had a good deal to do, viz., sugar, and the unkind things that had been said of its promoters. A patent had been taken out about 10 years ago by Messrs. Hodge and Eastwicke for purifying sugar solution by electrolytical means, and it was worded so widely that it seemed almost to cover the case of a substance somewhat less sweet—sewage, to wit. He commended its perusal to those interested in the latter commodity.

Mr. FLETCHER endorsed the statements contained in his report, which had been referred to in the Paper.

Mr. C. E. CASSAL, having elicited that the results of the analyses given above were stated in parts per 100,000, proceeded to criticise the process on the ground that the purification was less complete than could be wished, and regretted that the meeting had been unable to listen to the whole of the reports by various eminent chemists, as much information might sometimes be gathered by reading between the lines. He welcomed any process less monstrous than the recent proposal to convey the whole of London sewage bodily to the sea—a scheme the useful effect of which appeared to be confined to the pecuniary advantage of its promoters.

Colonel JONES recalled the *furore* that the advent of the Webster process had caused at the Institution of Civil Engineers, and supposed it might be explained on the *omne ignotum pro magnifico* principle. It was remarkable that the very considerable effect of mere agitation, aëration, and subsidence upon sewage had been overlooked by most of those engaged in its purification. The result due to these simple agencies was invariably credited to each several process as it was devised. The first time attention had been directed to it appeared to be in the Blue Book of the proceedings of the Royal Commission appointed at the instance of Lord Bramwell.

Mr. DAVID HOWARD asked particularly what *time* was requisite for purification, as rapid subsidence was essential to the success of a process of this kind.

Dr. MESSEL feared that electrolytic oxygen would prove a costly oxidant, and doubted whether cast-iron plates could be used on account of their slow rate of solution.

Digitized by Google

Mr. A. P. TROTTER asked for further information as to the time required. Accepting Mr. Webster's figures, he had roughly calculated that the duration of treatment amounted to about 12 min., but should be glad of a definite statement on this point. The time necessary for subsidence of the sludge was an important factor, concerning which he should be glad to have accurate data.

Mr. C. C. HUTCHINSON attacked the figures that had been given as to the cost of treatment at Salford. According to his calculations and reckoning, the cost of one indicated horse-power at one penny an hour, and allowing for the cost of oil, labour, and maintenance, the necessary yearly expenditure for the treatment of 10,000,000 gallons per 24 hours, as at Salford, would amount to £21,000 to £24,000, which was about four times as much as the estimate Mr. Worth had given. The whole value of the process turned on this question of cost, and according to its decision it must stand or fall.

Mr. WORTH, in reply, regretted that he had to act as a substitute for Mr. Webster, owing to his less perfect familiarity with all the details of the process. Any questions which he was unable to answer would be replied to by Mr. Webster from the shorthand notes of the querist's remarks. He did not think the complete diminution of organisms referred to by Mr. Bischoff necessary or even desirable; a sterilised effluent, even if practicable, would be speedily swarming with life again. He could not, like Mr. Siller, point to a town where the process was in actual operation; but it must be remembered that the process was a young one, and had not been at work, as the A. B. C. process had, for 25 years. Still they hoped to emulate Mr. Siller's perseverance, and have a town of their own, possibly as important as Kingston, before the elapse of another quarter of a century. Though considering the sludge from the Webster process at least equal to that produced by the A. B. C. process, he did not expect to get £3. 10s. a ton for it, and congratulated Mr. Siller on his greater good fortune. It had been proved that fish would live in the effluent, though that was scarcely a criterion of its purity. The questions put by Messrs Birch and Cross would be referred to Mr. Webster, who would doubtless answer to them as stated above. He could assure Mr. Cassal that the elimination of the whole of the organic matter was unnecessary for the production of a safe effluent, and heartily endorsed his criticism of the proposed treatment of London sewage. He fearlessly challenged Col. Jones (who had unfortunately left) to shake a sample of London sewage, such as had been treated by the Webster process before the section for 20 minutes, or even longer, being convinced that such simple treatment would not suffice to effect its clarification. In reply to Mr. Howard, he stated that the Webster process undoubtedly caused more rapid subsidence, and that its inventor was alive to the necessity thereof. In reply to Mr. Trotter he could say that the maximum time of subsidence was about three hours. The figures to which Mr. Hutchinson objected were calculated on the assumption that coal at 10s. per ton could be used and give one indicated horse-power for a consumption of 2lb. per hour. It would be, perhaps, better to suspend judgment on some of the points under dispute until the report of the engineers and chemists having charge of the Salford experiment was issued, as it was to be published very shortly.

## THE ARTIFICIAL LIGHT OF THE FUTURE.*

BY PROF. EDWARD L. NICHOLS.

When we come to consider the quality of the light produced and the efficiency of the apparatus as a light-making machine, we find that the incandescent lamp of to-day produces the same quality of light which the earliest examples of its type were capable of giving. We find, however, that its light differs but little from that obtained by burning oil and gas.

It is true that the efficiency of the incandescent lamp has gradually risen from five to three watts per candle, but those who have had occasion to trace the discouraging life-curves of such lamps know how little real progress the change implies. We start a well-manufactured lamp at any temperature we please, provided that we do not pass a certain limit, beyond which the life of the lamp would be too seriously curtailed. The initial efficiency may be made as large as we please, within that limit; but it is only a question of a few days or hours when the lamp will have dropped to the dead level of mediocrity the five-watt level which seems to mark the confines of permanency in the case of incandescent carbon.

When we take a lamp and raise its electromotive force step by step, measuring the current, voltage, and candle-power at each stage of the experiment, and plot the curve which expresses the relation between the energy required and the light produced, we are gratified at the marked rise in efficiency which follows each slight increase in the temperature of the filament (Fig. 1). That rise of temperature, however, means shortening of the life of the carbon, is well known. Unfortunately, rise of temperature means much more than that. I will venture to show you a few life curves recently obtained in the laboratory of Cornell University. These curves enable us to see at a glance what happens during the curtailed existence of a lamp which is forced to undue brilliancy. I introduce them because they indicate very definitely the nature of the difficulties which confront us when we endeavour to increase the efficiency of an incandescent lamp by raising its temperature.

In the first instance a lamp was started at the candle-power indicated by the maker, and was held at constant voltage by means of the current from a storage battery. The initial candle-power was 16, which was obtained at the expenditure of 3·015 watts per candle. Measurements of electromotive force and current were made at intervals of about 10 hours during the 800 hours that the lamp lasted. The candle-power was redetermined at intervals of about 100 hours. The voltage never rose more than 0·65 volts above its initial value, and then only for a short time. The average electromotive force of the entire run was 0·40 volts below the initial

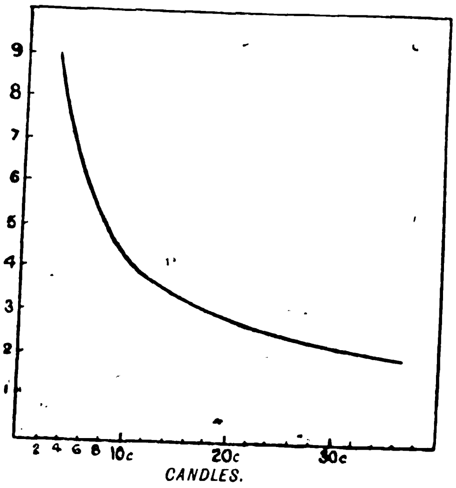

FIG. 1.—Efficiency Curves of an Incandescent Lamp.

value. The record of this lamp is contained in Fig. 2. It represents an individual case and not the average obtained from many lamps, but it is typical of the results which have been obtained with many. The characteristic features are rapid, followed by slower falling off in candle-power, the decrement amounting finally to more than 50 per cent., and rapid, followed by slower falling of efficiency, to a final value of 5·75 watts per candle. These changes were accompanied by continuous and marked increase in the resistance of the filament.

If it be asked whether this individual case represents a state of affairs common to all incandescent lamps, I can only say that in my

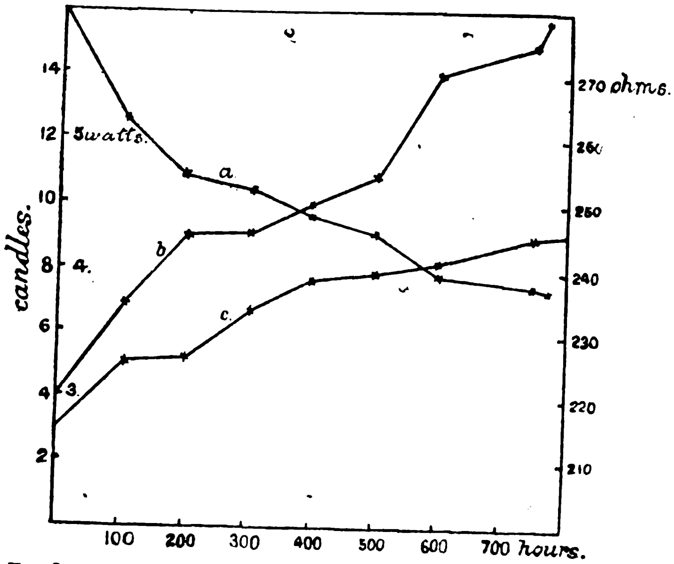

FIG. 2.—Curves showing the Changes which take place during the Life of a Lamp at Normal Voltage. *a* Candle Power, *b* Watts per Candle, *c* Resistance.

experience, which is certainly much less extensive than that of some others, I have known of no class of lamps the performance of which did not agree approximately with that indicated by these curves. Mr. W. H. Pierce, who described extended tests of the initial and average efficiency of incandescent lamps in a Paper read before the Institute of Electrical Engineers some time ago, recorded no exceptions to this rule of decreasing candle-power and efficiency with time.

The falling off in candle-power exhibited by lamps maintained at constant voltage can be met by a procedure not easily applicable, perhaps, in commercial work, but readily carried out where the

* Abstract of a Lecture before the New York Electric Club, Nov. 20, 1890.

Digitized by Google

object in view is simply to study the behaviour of the lamp under unusual conditions. The method consists in raising the electromotive force at short intervals of time by amounts sufficient to restore the candle-power to its normal value.

The results of such an experiment performed upon a lamp precisely similar to that from which the curves in Fig. 2 had been obtained are depicted graphically in Fig. 3. Under this treatment the life of the lamp in question was not quite 100 hours. The total rise in electromotive force during the test amounted to about nine volts; the efficiency decreased from 3·118 watts per candle to 3·468 watts per candle. The resistance of the filament rose from 221·6 to 234·8 ohms. During the first 50 hours the changes were slight, then occurred a sudden increase of resistance, accompanied by marked rise in electromotive force and in amount of energy consumed. The life history of the incandescent lamp at still higher temperatures does not differ essentially from that which we have just been considering, but the changes in question go on much more rapidly.

The performances were recorded of two lamps which were similar to those from which the curves in Figs. 2 and 3 had been obtained. The first of these was started at 57 candles. It was maintained at constant voltage for 11 hours and 30 minutes, when it went out. During its brief life the candle-power fell to 24·6, and the watts per candle increased from 1·58 to 3·09. The loss of candle-power during the experiment was 55 per cent., an amount which corresponds very closely with the loss suffered by the first lamp tested during the 800 hours that it lasted. In the case of the other lamp, the initial candle-power (64 candles) was maintained throughout. Its life under these circumstances was 140 minutes, during which short period it had been found necessary to raise the electromotive

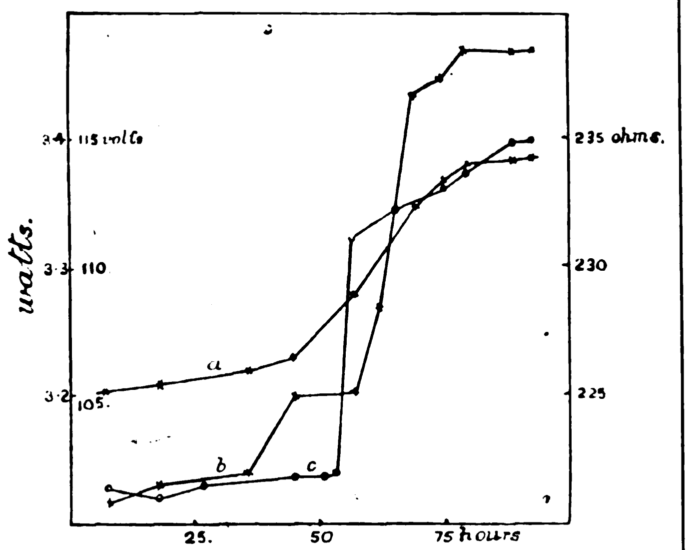

FIG. 3.—Life Curves of Incandescent Lamp at Normal Candle-power (Candle-power Constant), the Volts being Raised. *a* Volts, *b* Watts per Candle, *c* Resistance.

force from 114·08 volts to 129·53 volts. The efficiency of the lamp fell meantime from an initial value of 1·33 watts to 1·677 watts at the end of the first hour; then more and more rapidly to 1·945 watts at the end of the test.

The conclusion to be reached from these data, and from the great mass of experimental results which has accumulated since the incandescent lamp has become an object of investigation, is only too evident. The efficiency of an illuminant in which carbon is the glowing material, is a function of the temperature. It appears that the incandescent lamp is fairly stable only at temperatures, for which its efficiency does not exceed about five watts per candle. We have just seen what occurs when one attempts to maintain lamps at degrees of incandescence corresponding to a much higher temperature. It is, perhaps, not possible to point out with perfect definiteness all the causes that are at work to reduce the candle-power. The black coating which gradually forms on the interior of the lamp-bulb intercepts more and more of the light from the filament as the age of the lamp increases.

The life curves were made as a necessary part of the investigation of the loss of light due to the opaque film, and I will venture to take from the work, as yet unpublished, the results which have been obtained in the case of the lamp to which the curves in Fig. 2 refer. These results are given graphically in Fig. 4. They show the amount of light of each wave length of the visible spectrum which the coating on the interior of the bulb absorbed. The measurements were made after the lamp had been in operation 100 hours, 200 hours, 400 hours, and 800 hours. In the diagram, abscissæ are wave lengths, and ordinates show the amount of light transmittted by the lamp-bulb at the above mentioned times, in terms of the amount which the bulb allowed to pass before the coating began to form. You will see by a glance at these curves that the absorbing power of the film was very nearly uniform throughout the spectrum, so that the blackening of the lamp had no appreciable effect upon the light which it emitted; also that the absorption at the end of 200 hours was considerably more than half as great as that at the end of 800 hours, and that the total loss of candle-power due to blackening was about 22 per cent.

These measurements enable us to account for rather more than one-third of the loss of candle-power suffered by the lamp. We are not with our present knowledge in position to speak so definitely concerning the other two-thirds, but the increase in the resistance in the carbon indicates another source of diminution. That gradual failure of the vacuum, which the use of the spark-coil would unquestionably have enabled the observers to detect, may well be answerable for the rest. Now, the temperature of an incandescent lamp filament at five watts per candle is very nearly the same as that of the carbon in the light-giving flames produced by the combustion of oils and gas, and it appears that the attempt to pass this temperature introduces difficulties of such a nature as to lead to the serious question whether we have not reached a definite limit, beyond which incandescent carbon ceases to be permanent. At that limit the efficiency of the lamp is very small indeed, 95 per cent. or more of the radiant energy emitted being of wave lengths too long to afford light.

As to the arc light, no more encouraging report can be made. On the contrary, it is perfectly well established that the quality of the light, instead of increasing, has fallen off in the course of the

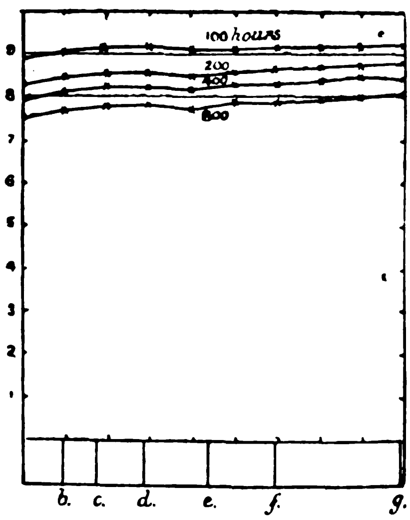

FIG. 4.—Curves of the Light at Different Parts of the Visible Spectrum. Given by a Lamp at Various Stages in its Life; Showing the Absorption by the Blackening of the Glass.

development of the lamp from the clock-work regulators of Dubosc and Foucault, with their slender carbons, to the commercial lamps of to-day.

The researches of Nakano, Marks, and others show that the efficiency of the arc is a definite function of the current density at the terminals of the carbons, increasing nearly in inverse ratio to the cross-section of the pencil. When the maximum current capacity of the latter has been reached, the efficiency is in the neighbourhood of 10 per cent., a value which is not likely to be greatly exceeded by any of the methods in vogue at the present day.

As Mr. Edward Weston says, in his discussion of Nakano's Paper on "The Efficiency of the Arc Lamp":—"The small amount of luminous energy, compared to the total energy employed, is a sad thing always." It seems only too probable that the limiting temperature at which carbon can be used for the production of light has been reached, and with it the maximum efficiency of artificial illumination.

The phenomena observed whenever we attempt to raise carbon above what may be termed its normal temperature of incandescence are significant, and they all point in one direction. We have just seen that when we raise the voltage of an incandescent lamp, we gain splendour of performance at the cost of permanence and stability. I might remind you, in this connection, that when the heat of gas flames is increased by forced draft, they become non-luminous; that the magnificent illuminating power of the arc lamp is not due to the intensely hot electric arc itself, filled, though it be, with carbon in process of transfer from the positive to the

Digitized by Google

negative pencil, but to the cooler carbon terminals. Such are the facts with which we have to deal when we consider the problem of increasing the efficiency of illumination by carbon; whether by direct combustion, by incandescence in vacuo, or by the use of the electric arc. In the face of the many unexpected things that have been accomplished through the agency of electricity, he would be rash who asserted that the possibilities of carbon had been exhausted. In view of the achievements of the time one is not permitted to declare the case hopeless; nevertheless, the outlook is not an encouraging one.

If, in what I have said thus far, I have drawn what seems to be a gloomy picture, it is not because I fail to recognise the importance of the electric light of to-day as a factor in our civilisation. Its superiority over other methods of artificial illumination is so well understood that it need not be enlarged upon here. Of its advantages we hear on every hand; of its limitations we hear less, and yet a knowledge of the latter is quite as important to those who are interested in its further development. The waste of 90 or 95 per cent. of non-luminous energy in the production of light is a matter to which we are apt to give little thought, and when the economic importance of the fact has been forced upon us by the study of the recent investigations which have been made to establish it, we find consolation in the thought that, after all, these percentages are somewhat larger than the corresponding values for candles, oil, and gas.

I have thought it not without interest, therefore, to discuss the behaviour of incandescent carbon under conditions, some of which are not "commercial," and to attempt to point out the significance of that behaviour. Now, if you will permit me, I will turn toward the future and consider the properties of some other sources of light,

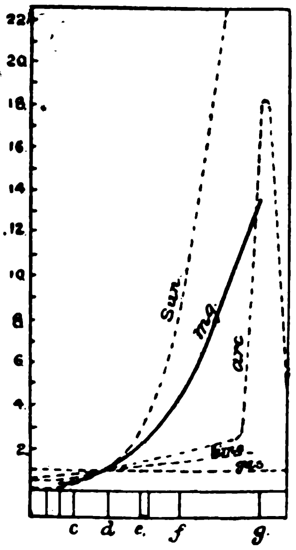

FIG. 5.—Light of the Sun, Magnesium, Arc, Lime and Gas, at Different Parts of the Spectrum.

with the view of inquiring whether they may not have a part to play in the artificial lighting of days to come.

What is to be the light of the future? From the standpoint of the engineer I will frankly say that I cannot answer that question, but abandoning the directly practical point of view, there is something to be said. I need offer no apology here for presenting facts, the application of which is at best remote, and the present importance of which is, therefore, rather scientific than utilitarian.

The number of elements and of compounds capable of sustaining a high temperature without dissociation or change of state is very large. Carbon is the only one of these, the capabilities of which as a source of light can be said to have been fully tested; and yet all the others, when heated to a proper point, emit light-giving radiation. Take for example the metallic oxides. We heat the oxide of calcium in our magic lanterns, and it gives us a light of great intensity, and but little inferior to the arc light in whiteness. The exceeding clumsiness of our method of rendering it incandescent, however, has prevented its adoption excepting for certain special purposes. We burn magnesium in fireworks and for photographic flash lights, and occasionally we indulge in the luxury of igniting a bit of the ribbon, and admiring, for an instant, the intense brilliancy of its flame. Now, magnesium is one of the most abundant elements on the face of our planet. It is a rather costly metal at present, being quoted at 50 cents an ounce in this country and at about half that price on the continent of Europe. Even under the limited demand for it which exists at present, it has fallen to about one-tenth of its price of a few years ago, and I feel sure that it lies within the power of the electrician to greatly further reduce the cost of production. Among artificial illuminants, magnesium has in one respect no equal. W. H. Pickering, who studied its spectrum in 1880, found it to approach sunlight in quality even more closely than the electric arc light does.

The precise character of the magnesium light is shown in Fig. 5. The abscissæ of the curves are wave lengths, and ordinates indicate the brightness of each portion of the spectrum of the magnesium flame in terms of that of the corresponding regions in the spectrum of gas light. The accompanying curves for the arc light and the limelight, introduced for convenience of comparison, are from measurements by Mr. W. S. Franklin and myself. These curves all refer to lights of the same candle-power. It will be seen that the magnesium flame is about 10 times brighter in the violet than a gas flame of the same power, and but little more than half as strong in the red. It will be seen, also, that it surpasses the electric arc everywhere beyond the yellow, save in a very limited region of the extreme violet. In order to appreciate fully the significance of these curves, one must have had occasion to compare the various lights to which they refer, placing them side by side and noting the effects. You are all aware that the magnesium light is very white and very powerful, but unless you have happened to see it in direct competition with our ordinary illuminants, you will be but dimly conscious of the difference between them.

A screen which is well lighted by incandescent lamps gives you the impression of a nearly uniform white surface. Its whiteness now, however, is a very different thing from that which it takes under the rays of the magnesium light. It sinks by comparison into a rather weak chocolate brown.

The proper way to compare sources of illumination is to determine their net and gross efficiencies; by which I mean, respectively, the ratio of total radiation to light giving radiation, and the ratio of the total amount of heat set free in the process of producing a candle-power of light, to the heat energy represented by the light itself. Now, the heat equivalent of a candle-power of gas, or of the light of an incandescent lamp at five watts per candle, is about 3·6 gramme-calories per minute. The total heat of combustion set free in generating a candle-power of gas light has been variously estimated at amounts ranging from 971 gramme-calories per minute (Preece) to 4,100 gramme-calories (Thomsen). Calculations based upon the theoretical heats of combination of illumiting gases give values nearer the latter than the former amount.

The amount of heat set free when a gramme of magnesium is converted into the oxide is very much less than that resulting from the combustion of a gramme of coal gas, and the light obtained is, as we have just seen, more than 32 times as great. The gross efficiency of the magnesium light must, therefore, be many times higher than that of gaslight. To be exact, we find, if we adopt the value given by Thomsen* for the heat of combination of magnesium (6,077), that the magnesium flame of one candle power should generate only 25 52 gramme-calories per minute. Taking the very low estimate of 1,000 gramme-calories per minute for gas, we find the gross efficiency of the magnesium flame to be about forty times that of gas light. The total luminosity of the arc light, for instance, may be considered fully 25 per cent. greater than that of gas.

We have seen that, weight for weight, magnesium affords more than 30 times the light obtained from gas, with the development of much less heat.

The character of the light corresponds to a temperature much above that of the electric arc, but the flame does not seem to be very hot. I have not as yet succeeded in obtaining a satisfactory measurement of the flame temperature, but the preliminary test, made at my request, gave approximately 1,400°C.

The large candle-power of the magnesium flame is due to its peculiar structure. A gas flame consists of a column of heated gases, the particles of which are rising rapidly from the jet of the burner. These carry off with them, by convection, 80 per cent. or more of the heat of combustion. The flame owes its luminosity entirely to the fact that near the base of the column a few particles of carbon, as yet unoxidised, are heated to incandescence. The total radiating surface of these particles is very insignificant, compared with the apparent superficial area of the flame; it is, indeed, not very different in extent from the radiating surface of the filament of an ordinary incandescent lamp of the same candle-power. The constitution of the magnesium flame is very different. The product of combustion is the oxide of magnesium, a white, amorphous solid of considerable density; it is, indeed, fully twice as heavy as the metal itself. The oxide remains, for the most part, in the place where it was first formed. It becomes intensely incandescent, and, having large radiating surface, it affords a large amount of light. Under such conditions, convection plays a minor part, and that which is the chief source of loss in the production of light by direct combustion of gaseous fuels is avoided. The gross efficiency is, therefore, very large.

The question of the *character* of the radiation from the magnesium flame offers greater difficulties. It is certain that neither platinum nor carbon at any temperature to which they can be sub-

* J. Thomsen: *Journal fur Praktische Chemie*, N. F., 16, p. 97.

Digitized by Google

jected in practice will give anything approximating to the quality of the magnesium light. I am convinced that we have to do here with a very different law of radiation from that which governs ordinary cases of incandescence. Taking carbon to represent the normal state of affairs, we may say that the radiation of magnesium oxides is out of all proportion to the temperature of incandescence; also that the percentage of those shorter wave lengths, which furnish green, blue, and violet light, is abnormally large.

That the radiation of the magnesium flame comes in part under the head of what Prof. E. Wiedemann has termed "Luminescence," I have little doubt. This word covers all those interesting phenomena known as phosphorescence, fluorescence, &c.

Luminescence is supposed to be due to a different class of molecular vibrations from those which cause ordinary incandescence. One of the characteristics of this class of vibrations is that it tends to produce selective radiation—that is to say, radiation in which a single wave length, or set of wave lengths, predominates. Another characteristic of luminescence is, that it is frequently, perhaps always, the result of previous treatment to which the glowing body has been subjected. This previous process may have been nothing more than the shining of the sun's rays upon the luminescent surface, as in those cases of phosphorescence, concerning which Becquerel has taught us so much.* It may have been in the course of some chemical reaction or process of crystallisation that the body received its preparation. In such cases the power lies latent until it is disengaged by the action of some external force. The immediate exciting cause may be mechanical, electrical, or thermal. In the last case, which most directly concerns us here, a certain rise of temperature is necessary to start the body into luminescence. When this critical temperature is below the red heat the phosphorescent glow attracts attention, and investigation follows. When, however, the temperature of luminescence is high, the effect, however marked it may be, is masked by the ordinary incandescence to be expected at that temperature, and it is overlooked. Luminescence by heat is perforce transient. It is due to the expenditure of energy which has been stored by previous action. If we wish to see the effect repeated, we must restore to the material the potential energy which it has lost.

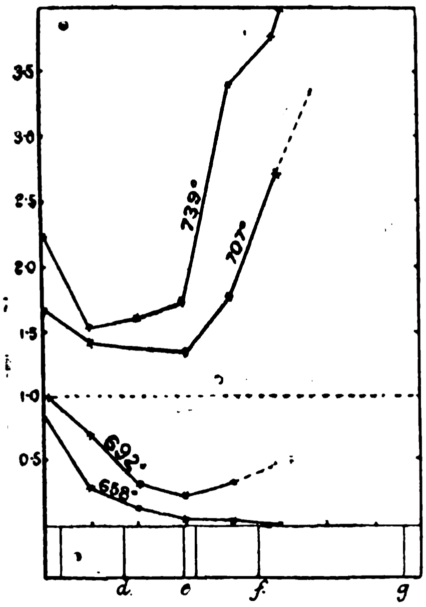

FIG. 6.—Radiation of Zinc Oxide at 658° and 692°C (First Stage), and at 707° and 739°C. (Second Stage) at Different Parts of the Visible Spectrum. Relative to Platinum.

I am not in a position to state positively that the glow of magnesium oxide is due to luminescent vibrations, but I am of the opinion that such will be found to be the case. Other metallic oxides also show peculiarities of radiation, which find their explanation most readily under that theory. While studying the distribution of energy in the visible spectrum of the lime light three years ago, Mr. Franklin and I found that a freshly ignited cylinder, under the oxy-hydrogen flame, glowed with a brilliancy equal to that of the magnesium light itself. This state of affairs lasted but a moment, however, and no amount of heating would bring out an old cylinder again into its initial splendour. It was plain that we were taking advantage of vibratory power stored in the lime at some stage in its preparation. These vibrations, disengaged by the blowpipe, gave out in a very short time, after which the performance of the lime degenerated rapidly to the level which corresponds to ordinary radiation at the temperature in question.

* Becquerel: *Annales de Chimie et de Physique* (3), 55.

You are all acquainted with the beautiful greenish-yellow light which the oxide of zinc emits under the flame of the blowpipe. It is entirely different from the light of the incandescent charcoal on which it lies, although the two cannot differ widely in temperature. The zinc oxide is luminescent; the carbon is simply incandescent, in the usual sense of the word. This is a case which lends itself readily to study, since the temperature at which the abnormal glow appears is a comparatively moderate one. Last summer I took the matter up, with the efficient co-operation of Mr. B. W. Snow, instructor in physics in Cornell University. We made a systematic comparison of the radiation from zinc oxide and from platinum, at temperatures between the red heat and 1,000°C., measuring temperatures and studying spectra by methods which I cannot dwell upon here. Since the results which we obtained are of a character to illustrate the points which seem to me most significant in this question of the radiation of the metallic oxides, I will indicate them graphically.

Zinc oxide is a rather brilliant white pigment. Its radiating power, therefore, according to the theory of exchanges, should be very small. At temperatures below 700°C. we found it to be very much lower than that from platinum throughout the spectrum, and the light from the oxide to be a duller red. Fig. 6 shows the results of the comparison. In this and the subsequent curves, platinum is taken as the standard. The curves show how the oxide of zinc compares with platinum in strength of radiation. The law according to which the visible radiation of platinum rises from zero at the extreme red heat, as the temperature rises, varies with the wave length. It had to be especially determined, for the purposes of our investigation, in each region of the spectrum to which our measurements were extended.

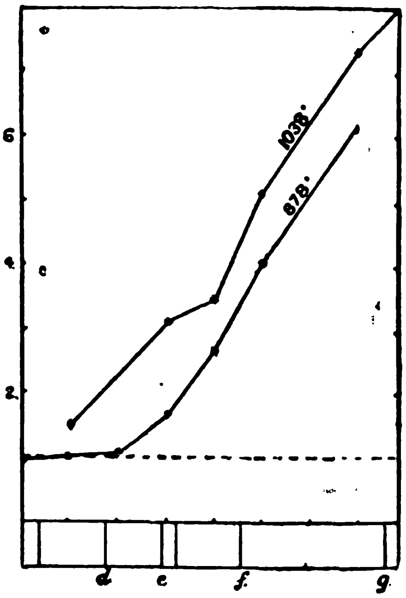

FIG. 7.—Radiation from Zinc Oxide at 878° and 1,038°C. at Different Parts of the Visible Spectrum. Relative to Platinum.

At about 700deg. a sudden change occurs in the character of the light from the oxide. It becomes brighter than the platinum of the same temperature, the increase showing itself principally at the ends of the spectrum. In Fig. 6 (707deg. and 739deg.) we have curves which represent this second phase. The emanations are selective to a marked degree, the yellow being relatively very weak. Measurements of fresh films of the oxide at still higher temperatures revealed the further development of the abnormal radiation of this substance. Fig. 7, which gives curves for 878deg. and 1,038deg., shows the transition into a third, and, apparently, a final stage. The red end of the spectrum loses its prominence, and the curve seems to be developing into a straight line, the trend of which is such as to indicate that zinc oxide, as we pass from the longer to the shorter wave lengths of its spectrum, increases in superiority over platinum at the same temperature. It soon became evident from the character of our results that the radiation at temperatures above about 800deg. was of a very evanescent sort, falling off in intensity and changing in quality from the first instant in which the oxide was heated. To follow these rapid changes proved a trying task. By taking a great many fresh films of the oxide and watching the time changes of one portion of the spectrum after another, however, we were able to obtain data from which the curves in Fig. 8 were drawn. These show the intensity of radiation and its character, relative again to that of platinum, after the oxide had been maintained 1,013deg. for a period of 30secs., of 60sec., of

Digitized by Google

300secs. and of 600secs. At the end of the 10min. the changes, although not entirely completed, were very slow.

The evidence of the existence of luminescence afforded by these measurements seems to us to be nearly conclusive. Extension of the investigation to other of the metallic oxides and to wider ranges of temperature, would, doubtless, lead to results more striking.

The application of all this to the problem of the light of the future is as follows: The fundamental question is that of efficiency. High efficiency at low temperatures means selected radiation, which appears to be a characteristic of luminescence and not of ordinary incandescence. The study of the radiation of the metallic oxides above the red heat reveals the existence of properties which lead us to regard them as being luminescent "by heat." It is from such bodies that radiation of high efficiency is to be looked for. We have in magnesium oxide a member of this particular class, and we have seen that when it is heated in the process of formation it gives us a light, the efficiency of which is unapproached by that of other artificial illuminants.

The problem is easily stated. (1) We need a body which is rendered vividly luminescent by heat. The metallic oxides would seem to offer us many such. (2) The material is to be brought to the temperature at which its luminescence is most marked. Does it not seem probable that the best method, as in the case of carbon, will not be that of direct combustion, but of heating through the agency of the electric current? (3) The material must be restored from time to time. Whether rejuvenation is to be secured through electrical, chemical, actinic, or mechanical means remains to be determined.

Luminescence "by heat" offers, however, only a partial solution of the problem of the highest efficiency. However great the efficiency of the luminescent itself, it is accompanied by incandescence of the ordinary kind. The ultimate solution is to be sought for along other lines. Incandescence is too expensive a means of exciting luminescence. There are many other ways in which it may be generated; friction, chemical action, the impact of light waves, electrical excitation, certain vital processes, are known to result in the production of light. The physics of these phenomena is, for the most part, undeveloped. I know of but two attempts to determine the efficiency of this "light without heat," as it has sometimes been called. The intensity is, as a rule, very small, and the heat has doubtless been regarded as quite below the range of even our most sensitive apparatus. One of these two cases is of especial interest to the electrician. It is that of the spark discharge in vacuo. Prof. S. P. Langley and Mr. F. W. Very, in a recent remarkable Paper, entitled, "The Cheapest Form of Light," speak of the heat generated in the Geissler tube as so minute as to seem to defy direct investigation. It has, however, been successfully measured by Dr. Staub, of the University of Zurich, by means of one of the most delicate instruments for the measurement of heat—the Bunsen ice calorimeter.*

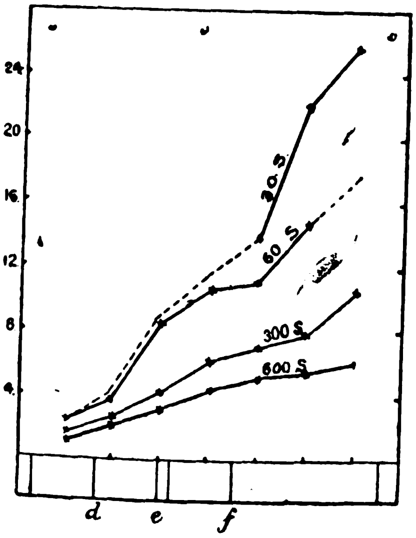

FIG. 8.—Radiation from Zinc Oxide at 1,013°C. for a period of 30, 60, 300, and 600 seconds.

In Staub's experiments the vacuum tube was smoked with lamp-black and inserted in the ice calorimeter. The ice melted in a given time afforded a measure of the total heat generated by the electric discharge through the tube. A repetition of the determination with the unsmoked tube, under which conditions the light-giving rays could escape, gave the energy of the non-luminous radiation. The efficiency was found to be 3·268 per cent. The extremely small candle-power of the light derived from the electric discharge in vacuo may seem to preclude all questions of its utilisation in practical illumination. The result is one, however, which should not be lost sight of. It suggests a field of investigation which may prove unexpectedly fruitful.

The Geissler tube effect was not the source to which Langley and Very applied the term "the cheapest form of light." The subject of their research was the light of a Cuban fire-fly. Their work cannot fail to excite the highest admiration of everyone who is able to appreciate the difficulties of such an investigation. The exploration of the heat spectrum of so insignificant a source of light is a task which very few physicists would, I think, have considered practicable, but it has been carried through by these investigators to complete success.

When we study the curve of distribution of energy in the spectrum of the fire-fly thus obtained, and compare it with the corresponding curves for gas light, the arc light and sun light, we find the expression, "the cheapest form of light," which is applied to the light of the fire-fly by Langley and Very, to be fully justified. All the energy of its spectrum is massed within the narrow limits of the visible spectrum, and what is more, by far the greatest part of it is in the form of rays which are especially important for the purposes of radiation, the particular rays which give us yellow and green light. The non-luminous radiation which accompanies the light of the fire-fly seems to be so insignificant that it was with difficulty that it could be estimated, even with the almost inconceivably delicate apparatus used by Langley and Very. They give the efficiency as about 400 times as great as that of a gas flame. It cannot fall appreciably below 100 per cent.

In what I have said I fear that I have fallen far short of what might have been expected of a lecturer on the artificial light of the future. I have endeavoured to show that the efficiency of our present methods is too low to meet the demands of the future for economical illumination, and that whether we ever succeed in approaching the perfect economy of nature's light-making processes, as exemplified in the fire-fly, or not, there are many sources of light which promise high efficiency.

## THE ELECTRO-MAGNET.*

BY PROFESSOR SILVANUS P. THOMPSON.

*(Continued from page 111.)*

The rule for calculating the intensity of the magnetic force at any point on the axis of the long tubular coil within this region where the force is uniform is:—

$$H = \frac{4}{10}\pi \times \text{the ampere-turns per cm. of length.}$$

And, as the total magnetising power of a tubular coil is proportional not only to the intensity of the magnetic force at any point, but also to the length, the integral magnetising effect on a piece of iron that is inserted into the coil may be taken as practically equal to $\frac{4}{10}\pi\times$ the total number of ampere-turns in that portion of the tubular coil which surrounds the iron. If the iron protrudes as much as three diameters at both ends, the total magnetising force is simply $\frac{4}{10}\pi\times$ the whole number of ampere-turns.

Now that case is, of course, not the one we are usually dealing with. We cannot procure steel magnets with unalterable poles of fixed strength. Even the hardest steel magnet, magnetised so as to give us a permanent pole near or at the end of it—quite close up to the end of it when you put it into a magnetising coil—becomes by that fact further magnetised. Its pole becomes strengthened as it is drawn in, so that the case of an unalterable pole is not one which can actually be realised. One does not usually work with steel; one works with soft-iron plungers which are not magnetised at all when at a distance away, but become magnetised in the act of being placed at the mouth of the coil, and which become more highly magnetised the further they go in. They tend, indeed, to settle down, with the ends protruding equally, for that is the position where they most nearly complete the magnetic circuit; where, therefore, they are most completely and highly magnetised. Accordingly, we have this fact to deal with, that whatever may be the magnetising forces all along a tube, the magnetism of the entering core will increase as it goes on. We must therefore have recourse to the following procedure. We will construct a curve in which we will plot not simply the magnetising forces of the spiral at different point, but the product of the magnetising forces into the magnetism of the core which

* A series of four Cantor Lectures delivered before the Society of Arts, January—February, 1890.

Digitized by Google

itself increases as the core moves in. The curve with a flat top to it corresponds to an ideal case of a single pole of constant strength. We wish to pass from this to a curve which shall represent a real case, with an iron core. Let us still suppose that we are using a very long core, one so long that when the front pole has entered the coil the other end is still a long way off. With an iron core of course it depends on the size and quality of the iron as to how much magnetism you get for a given amount of magnetising power. When the core has entered up to a certain point, you have all the magnetising forces up to that point acting on it; it acquires a certain amount of magnetism, so that the pull will necessarily go on increasing, and increasing although the intensity of the magnetic force from point to point along the axis of the coil remains the same, until within about two diameters from the far end. Although the magnetic force inside the long spiral remains the same, because the magnetism of the core is increasing, the pull goes on increasing and increasing (if the iron does not get saturated) at an almost uniform rate all the way up until the piece of iron has been poked pretty nearly through to the distant end. In Fig. 61, a tubular coil, B A, is represented. Suppose a long iron core is placed on the axis to the right, and that its end is gradually brought up toward B. When it arrives at X the pull becomes sensible, and increases at first rapidly, as the core enters the mouth of the tube, then gently, as the core travels along, attaining a maximum, C, about at the further end, A, of the tube. When it approaches to the other end, A, it comes to the region where the magnetising force falls off, but the magnetism is still going on increasing, because something is still being added to the total magnetising power, and these two effects nearly balance one another, so that the pull arrives at the maximum. This is the highest point, C, on the curve; the greatest pull occurring just as the end of the iron core arrives at the bottom or far end of the tubular coil; from which point there is a very rapid

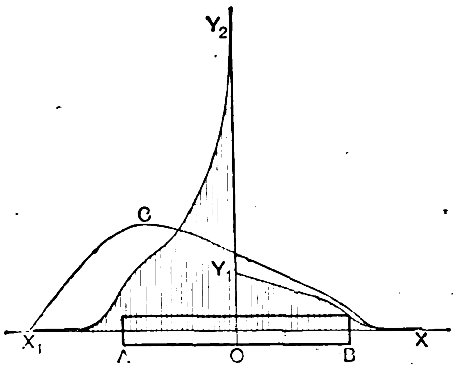

Fig. 61.—Diagram of Force and Work of Coil-and-Plunger.

falling off. The question of rapidity of descent from that point depends only on how long the core is. If the core is a very long one, so that its other pole is still very far away, you have a long, slow descent going on over some three diameters, and gradually vanishing. If, however, the other pole is coming up within measureable distance of B, then the curve will come down more rapidly to a definite point, $X_1$. To take a simple case where the iron core is twice as long as the coil, its curve will descend in pretty nearly a straight line down to a point such that the ends of the iron rod stand out equally from the ends of the tube.

Precisely similar effects will occur in all other cases where the plunger is considerably longer than (at least twice as long as) the coil surrounding it. If you take a different case, however, you will get another effect. Take the case of a plunger of the same length as the coil, then this is what necessarily happens. At first the effects are much the same, but as soon as the core has entered about half, or a little more than half its length, you begin to have the action of the other pole that is left protruding outside tending to pull the plunger back; and although the magnetising force goes on increasing the further the plunger enters, the repulsion exerted by the coil on the other pole of the plunger keeps increasing still faster as this end nears the mouth of the coil. In that case the maximum will occur at a point a little further than half-way along the coil, and from that point the curve will descend and go to zero at A; that is to say, there will be no pull when both ends of the plunger coincide with the two ends of the coil. If you take a plunger that is a little shorter than the coil, then you find that the attraction comes down to zero at an earlier period still. The maximum pull occurs earlier, and so does the reduction of the pull to zero; there being no action at all upon the short core when it lies wholly within that region of the tube within which the intensity of the magnetic force is uniform. That is to say, for any portion of this tube corresponding to the flat top of the curve of Fig. 60, if the plunger of iron is so short as to lie wholly within that region, then there is no action upon it; it is not pulled either way. Now these things can be not only predicted by the help of such a law as that, but verified by experiment. Here is a set of tubular coils which we use at the Finsbury Technical College for the purpose of verifying these laws. There is one here about 9in. long, one about half that length, another just a quarter. They are all made alike in this way, that they have exactly the same weight of copper wire, cut from the same hank, upon them. There are, of course, more turns on the long one than on the shorter, because with the shorter ones each turn requires on the average a larger amount of wire, and therefore the same weight of wire will not make the same number of windings. We use that very simple apparatus, a Salter's balance, to measure the pull exerted down to different distances on cores of various lengths. You find in every case the pull increases and becomes a maximum, then diminishes. We will now make the experiment, taking first a long plunger, roughly about twice as long as the coil. The pull increases as the plunger goes down, and the maximum pull occurs when the lower end gets to the bottom; beyond that the pull is less. Using the same plunger, with these shorter coils, one finds the same thing; in fact, more marked, for we have now a core which is more than twice the length of the coil. So we find, taking in all these cases, that the maximum pull occurs, not when the plunger is half way in, as the books say, but when the bottom end of it is just beginning to come out through the bottom of the coil that we are using. If, however, we take a shorter plunger, the result is different. Here is one just the same length as the coil. With this one the maximum pull does occur when the core is about half way in; the maximum pull is just about at the middle. Again, with a very short core—here is one about one-sixth of the length of the coil—the maximum pull occurs as it is going into the mouth of the coil; and, when both ends have gone in so far that it gets into the region of equable magnetic field, there is no more pull on one end than on the other; one end is trying to move with a certain force down the tube, and the other end is trying to move with exactly equal force up the tube, and the two balance one another. If we carry that to a still more extreme case, and employ a little round ball of iron to explore down the tube, you will find this curious result, that the only place where any pull occurs on the ball is just as it is going in at the mouth. For about half an inch in the neck of the coil there is a pull; but there is no pull down the interior of the tube at all, and there is no measurable pull outside.

Now these actions of the coil on the core are capable of being viewed from another standpoint. Every engineer knows that the work done by a force has to be measured by multiplying together the force and the distance through which its point of application moves forward. Here we have a varying force acting over a certain range. We ought, therefore, to take the amount of the force at each point, and multiply that by the adjacent little bit of range, averaging the force over that range, and then take the next value of force with the next little bit of range, and so consider in small portions the work done along the whole length of travel. If we call the length of travel $x$, the element of length must be called $dx$. Multiply that by $f$, the force. The force multiplied by the element of length gives us the work, $dw$, done in that short range. Now the whole work over the whole travel is made up of the sum of such elements all added together; that is to say, we have to take all the various values of $f$, multiply each by its own short range $dx$, and the sum of all those, writing $\int$ for the sum, would be equal to the sum of all the work; that is to say, the whole work done in putting the thing together will be written:—

$$w = \int f\,dx.$$

Now what I want you to think about is this:—Here, say, is a coil, and there is a distant core. Though there is a current in the coil it is so far away from the core that practically there is no action; bring them nearer and nearer together; presently they begin to act on one another, there is a pull, which increases as the core enters, then comes to a maximum, then dies away as the end of the core begins to protrude at the other side. There is no further pull at all when the two ends stand out equally. Now there has been a certain total amount of work done by this apparatus. Every engineer knows that if we can ascertain the force at every point along the line of travel the work done in that travel is readily expressed by the area of the force-curve. Think of the curve X C X, in Fig. 61, the ordinates of which represent the forces. The whole area underneath this curve represents the work done by the system, and therefore represents equally the work you would have to do upon it in pulling the system apart. The area under the curve represents the total work done in attracting in the iron plunger, with a pull distributed over the range X $X_1$.

Now I want you to compare that with the case of an electromagnet where, instead of having this distributed pull, you have a much stronger pull over a much shorter range. I have endeavoured to contrast the two in the other curves drawn in Fig 61. Suppose

Digitized by Google

we have our coil, and suppose the core, instead of being made of one rod such as this, were made in two parts, so that they could be put together with a screw in the middle, or fastened together in any other mechanical way. Now first treat this rod as a single plunger, screw the two parts together, and begin with the operation of allowing it to enter into the coil, the work done will be the area under the curve which we have already considered. Let us divide the iron core into two. First of all put in one end of it; it will be attracted up in a precisely similar fashion, only being a shorter bar, the maximum would be a little displaced. Let it be drawn in up to half way only: we have now a tube half filled with iron, and in doing so we shall have had a certain amount of work done by the apparatus. As the piece of iron is shorter, the force-curve, which ascends from X to $Y_1$, will lie little lower than the

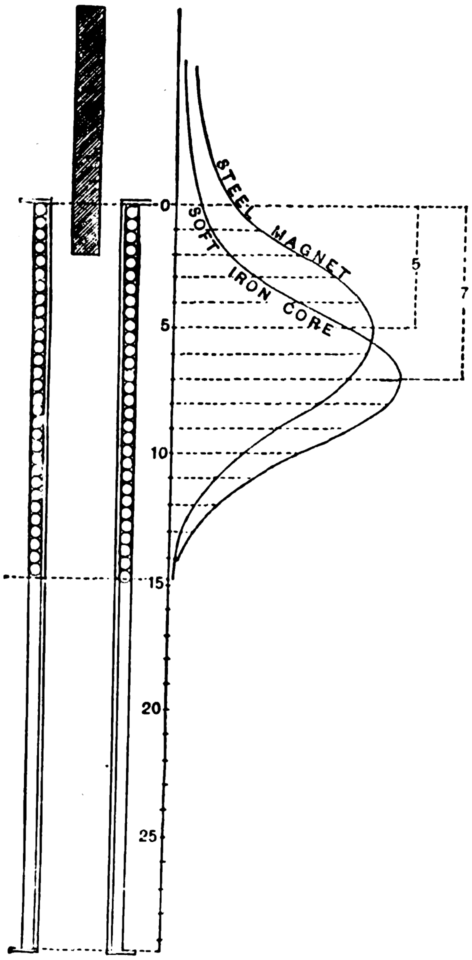

Fig. 62.—Von Feilitsch's Experiment on Plungers of Iron and Steel.

curve, $X C X_1$; but the area under that lower curve, which stops halfway, will be the work done by the attraction of this half core. Now go to the other end and put in the other half of the iron. You now have not only the attraction of the tube, but that of the piece which is already in place, acting like an electro-magnet. Beginning with a gentle attraction, it soon runs up, and draws the force-curve to a tremendously steep peak, becoming a very great force when the distance asunder is very small. We have, therefore, in this case a totally different curve made up of two parts, a part for the putting in of the first half of the core, and a steeper part for the second; but the net result is, we have the same quantity of iron magnetised in exactly the same manner by the same quantity of electric current running round the same amount of copper wire—that is to say, the total amount of work done in these two cases is necessarily equal. Whether you allow the entire plunger to come in by a gentle pull over a long range, or whether you put the core in in two pieces—one part with a gentle pull, and the other with a sudden spring up at the end—the total work must be the same; that is to say, the total area under our two new curves must be the same as the area under the old curve. The advantage, then, of this coil-and-plunger method of employing iron and copper is, not that it gets any more work out of the same expenditure of energy, but that it distributes the pull over a considerable range. It does not, however, equalise it altogether over the range of travel.

A number of experimental researches have been made from time to time to elucidate the working of the coil-and-plunger. Hankel, in 1850, examined the relation between the pull in a given portion of the plunger and the exciting power. He found that, so long as the iron core was so thick and the exciting power so small that magnetisation of the iron never approached saturation, the pull was proportional to the square of the current, and was also proportional to the square of the number of turns of wire. Putting these two facts together we get the rule—which is true only for an unsaturated core in a given position—that the pull is proportional to the square of the ampere-turns. This might have been expected, for the magnetism of the iron core will, under the assumptions made above, be proportional to the ampere-turns, and the intensity of the magnetic field in which it is placed being also proportional to the ampere-turns, the pull, which is the product of the magnetism and of the intensity of the field, ought to be proportional to the square of the ampere-turns.

Dub, who examined cores of different thicknesses, found the attraction to vary as the square root of the diameter of the core. His own experiments show that this is inexact, and that the force is quite as nearly proportional to the diameter as to its square root. There is, again, reason for this. The magnetic circuit consists largely of air-paths by which the magnetic lines flow from one end to the other. As the main part of the magnetic reluctance of the circuit is that of the air, anything which reduces the air reluctance increases the magnetisation, and, consequently, the pull. Now, in this case, the reluctance of the air-paths is mainly governed by the surface exposed by the end portions of the iron core. Increasing these diminishes the reluctance, and increases the magnetisation by a corresponding amount. Von Waltenhofen, in 1870, compared the attraction exerted by two

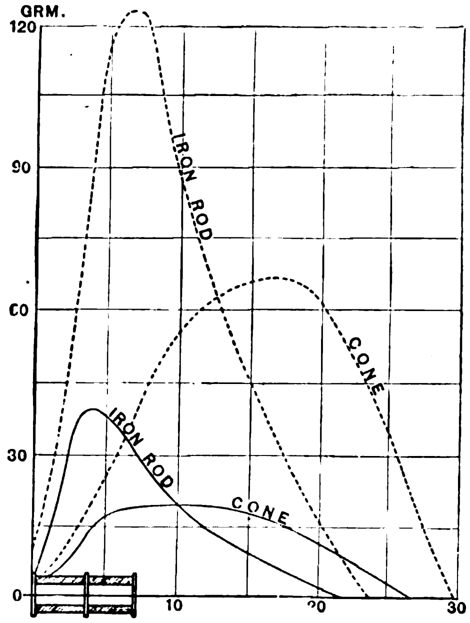

Fig. 63.—Bruger's Experiments on Coils and Plungers.

equal (short) tubular coils on two iron cores, one of which was a solid cylindrical rod, and the other a tube of equal length and weight, and found the tube to be more powerfully attracted. Doubtless the effect of the increased surface in diminishing the reluctance of the magnetic circuit explains the cause of the observation.

Von Feilitzsch compared the action of a tubular coil upon a plunger of soft iron with that exerted by the same coil upon a core of hard magnetised steel of equal dimensions. The plungers (Fig. 62) were each 10·1 centimetres long, the coil being 29·5 centimetres in length, and 4·2 in diameter. The steel magnet showed a maximum attraction when it had plunged to a depth of 5 centimetres, whilst the iron core had its maximum at a depth of 7 centimetres, doubtless because its own magnetisation went on increasing more than did that of the steel core. As the uniform field region began at a depth of about 8 centimetres, and the cores were 10·1 centimetres in length, one would expect the attracting force to come to zero when the cores had plunged into a depth of about 18 centimetres. As a matter of fact, the zero point was reached a little earlier. It will be noticed that the pull at the maximum was a little greater in the case of the iron plunger.

The most careful researches of late years are those made by Dr. Theodore Bruger, in 1886. One of his researches, in which a cylindrical iron plunger was used, is represented by two of the curves in Fig. 63. He used two coils, one 3½ centimetres long, the other 7 centimetres long. These are indicated in the bottom left-hand corner. The exciting current was a little over 8 amperes. The cylindrical plunger was 39 centimetres long. The plunger is sup-

Digitized by Google

posed in the diagram to enter on the left, and the number of grammes of pull is plotted out opposite the position of the entering end of the plunger. As the two curves show by their steep peaks, the maximum pull occurs just when the end of the plunger begins to emerge through the coil; and the pull comes down to zero when the ends of the core protrude equally. In this Figure the dotted curves relate to the use of the longer of the two coils. The height of the peak, with the coil of double length, is nearly four times as great, there being double ampere-turns of excitation. In some other experiments, which are plotted in Fig. 64, the same core was used with a tubular coil 13 centimetres long. Using currents of various strengths, 1·5 ampere, 3, 4·8, 6, or 8 amperes, the

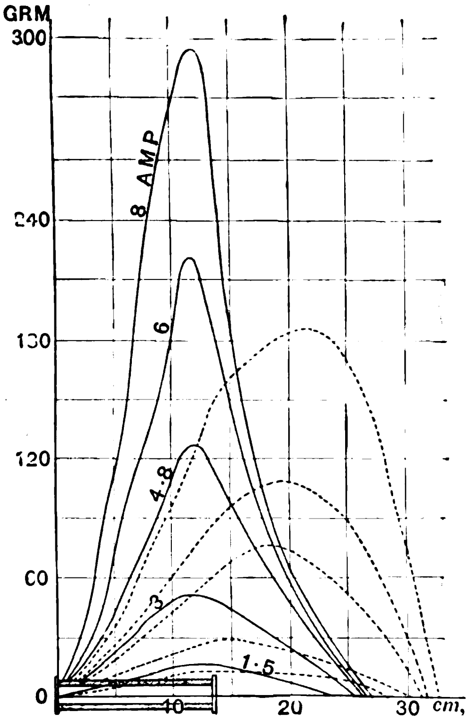

Fig. 64.—Bruger's Experiments, using Currents of Various Strength.

pull is, of course, different, but, broadly, you get the same effect, that the maximum pull occurs just where the pole begins to come out at the far end of the tubular coil. There are slight differences; with the smallest amount of current the maximum is exactly over the end of the tube, but with currents rather larger, the maximum point comes a little farther back. When the core gets well saturated the force curve does not go on rising so far; it begins to turn over at an earlier stage, and the maximum place is necessarily displaced a little way back from the end of the tube. That was also observed by Von Waltenhofen when using the steel magnet.

*(To be continued.)*

## THE PHYSICAL SOCIETY.

At the meeting of this Society, held on the 28th of November, the following communications were made:—

### "Additional Notes on Secondary Batteries."

By Dr. J. H. Gladstone, F.R.S., and W. Hibbert, F.I.C.

The authors observed that during the publication of a series of Papers by Dr. Gladstone and Mr. Tribe, in *Nature*, 1887, on "The Chemistry of the Secondary Battery," a discussion had arisen as to whether the sulphates of lead to which they ascribed so important a part in the reaction could be reduced by electrolysis. Experimental proof of the possibility of this was given at the time, even supposing the sulphate of lead to be pure, and the authors of the Papers maintained that when, as was the case in practice, the sulphate was intimately mixed with peroxide there was no difficulty whatever about the matter. ("The Chemistry of the Secondary Battery," *Nature* Series.) It was believed, however, by some, that a sub-sulphate of lead was produced on the plate, and that this was the explanation of the difficulty experienced in reducing those masses of salt which were sometimes formed in practice. Last year, however, Professor Frankland (*Royal Soc. Proceedings*, Vol. XLVI., page 304) (*Electrician*, Vol. XXIII., p. 470) published a Paper in which he described what he considered to be two definite sub-sulphates. The sub-sulphate produced from litharge has been already considered in a Paper communicated by the present authors to the Society last June (*Phil. Mag.*, Vol. XXX., p. 162). With regard to the compound formed by the action of sulphuric acid upon minium, Prof. Frankland has found its formula to be $S_2Pb_3O_{10}$, the same percentage composition as that found by Gladstone and Tribe in their Paper already quoted. They, however, considered it to be a mixture of $PbO_2$ with $2PbSO_4$. To decide as far as possible between these two views, some of the red substance was prepared by treating minium with a 10 per cent. solution of sulphuric acid in water, and treating the resulting compound with acetate of ammonium, which is known to dissolve sulphate of lead, but which would not be likely to decompose such a compound as $S_2Pb_3O_{10}$. The result of this was a residue much darker than the original in colour, and containing 82 per cent. of lead; that is to say, approximating in composition to $PbO_2$, which contains 86·6 per cent. of lead, and a colourless solution of pure $PbSO_4$. This result confirmed the view of the present authors; but, as they point out, it is, of course, impossible to affirm that a sub-sulphate is ever formed in the reaction of secondary cells; but what they have proved is, that all that we know is perfectly consistent with the old and simpler supposition that $PbSO_4$ is alternately formed and decomposed.

The other point considered was the action of sulphuric acid on lead. The authors pointed out that in their former Paper to the Society they had described a comparative experiment in which dilute sulphuric acid either alone or mixed with a small quantity of sodium sulphate was allowed to act on spongy lead. The experiment continuing for about five months. The evolution of hydrogen gas continued for such a length of time that they thought it would be of interest to analyse the resulting substance. When the lead was treated with pure sulphuric acid the residue consisted of 82 per cent. of sulphate of lead and 18 per cent. of metallic lead, while if the acid was mixed with sodium sulphate it consisted of 89 per cent. of lead sulphate and 11 per cent. of metallic lead. The authors point out that although the action of the acid on the lead was diminished in its initial stages by the presence of sodium sulphate, the final result was in the other direction. They consider that the whole of the spongy lead would have been converted into sulphate if it had not been for the large amount of insoluble salt which protected the remaining particles. They suggest that this result throws light upon the reason why a lead plate deteriorates during a long rest.

#### DISCUSSION.

Mr. G. H. ROBERTSON, who had used ammonium acetate to analyse plugs from storage cells, said he had arrived at results much the same as those stated by the authors.

Mr. SWINBURNE said Dr. Frankland was absent, but, without agreeing with him, he would suggest that Dr. Frankland might say that ammonium acetate decomposed the subsalt $Pb_3S_2O_{10}$, and then dissolved the sulphate $PbSO_4$. The question might be attacked by acting on equal quantities of the substance and the mixture $PbO_2$, $2PbSO_4$ in a calorimeter with ammonium acetate, to see if the same heat is produced. This would show whether the substance is a mixture or a compound.

Dr. S. P. THOMPSON was glad that the authors allowed a possibility of basic sulphate being formed, for it was well known that an almost irreducible sulphate resulted from leaving a cell nearly discharged. This, he thought, would point to a possible formation of a basic sulphate from $PbO$ and $PbSO_4$.

Mr. SWINBURNE did not see where the PbO came from, except in newly pasted negatives, and he knew of no evidence of an intermediate stage of oxide on the plates. They appear to change directly to sulphate.

Dr. THOMPSON said that a rapid discharge was known to produce basic salts.

This Mr. SWINBURNE thought due to deficiency of acid near the plates. Peroxide, he said, could not be formed on the negative, without the acid was heterogeneous, and gave rise to local currents.

Mr. W. HIBBERT, referring to Mr. Swinburne's statement, said he had put one plate of spongy lead into strong acid and another into weak, and from this arrangement obtained a fairly large current. As regards the basic sulphate spoken of by Dr. Thompson, he did not think there was much probability of its being formed. Time, he said, had an important influence on a partially discharged cell, and he would not expect to easily reduce the $PbSO_4$ formed by the long continued action of lead on sulphuric acid.

The PRESIDENT inquired whether Mr. Hibbert's argument would apply to a fully-charged cell.

Mr. HIBBERT, in reply, said that in this case the time required to produce sufficient sulphate to be irreducible would be very much longer, for in a partially-discharged cell much sulphate was already formed.

Dr. GLADSTONE said he had anticipated that Dr. Frankland would raise the objection referred to by Mr. Swinburne. As far as he was aware, there was no direct evidence either way; but he thought the suggested decomposition was improbable. If he acted on a mixture of $PbO_2$ and $PbSO_4$, he would expect to get the results actually obtained. Mixtures, however, were difficult to deal with, and the results not conclusive, for the physical condition of the mixture was not the same as that of the actual products. Referring to Dr. Thompson's remarks, he understood that it was the basic sulphate which he (Dr. Thompson) considered irreducible.

Digitized by Google

Dr. Frankland, however, believed this sulphate more easily reduced than $PbSO_4$.

The PRESIDENT remarked that he thought Dr. Frankland had two reasons for his belief in the existence of the basic sulphates. One of these was the difficulty in reducing normal sulphate, whilst the other was based on the rapid fall of E.M.F. at a certain part of the discharge. It was at this point that Dr. Frankland thought the new sulphate formed, and to meet this argument it was necessary to find some other explanation of the rapid fall. In this connection, he (the President) inquired whether there was sufficient peroxide formed on the negative plate to account for the drop. On this point Dr. Gladstone could not speak decisively.

## AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *November* 21, 1890.

**Compound Winding.**—At the regular monthly meeting of the American Institute of Electrical Engineers on Tuesday evening of this week a Paper was read by Dr. Louis Bell, editor of the *Electrical World*, on "The Theory of Compound Winding for Constant Potential." The Paper gave a brief *resumé* of the somewhat incomplete formulæ used by different designers in a calculation of compound winding for constant potential, and then developed a slightly different and more complete formula, which was thought to be better suited for this purpose. Starting with the plain shunt machine, the various losses which must be compensated for by the use of series turns on the field coils, were considered separately. These were, first, the fall of potential due to the resistance of the armature; second, the loss due to the decreased effect of the shunt when the series turns are added; and, third, the loss due to the demagnetising effect of the armature. In the discussion of the Paper, the interesting point was brought out by Mr. Entz that the resistance of the air space between the armature and pole pieces cannot be considered a constant, since the angle at which the lines of force cross the air gap, and consequently the length of the path which they take is variable. It was thought that in some cases the variation in the angle which the lines of force make with a line joining the centre of the pole pieces might be as much as 45 degrees.

**The Artificial Light of the Future.**—On Tuesday evening of this week Prof. Edward L. Nichols, of Cornell University, gave a very interesting lecture before the New York Electric Club. After reviewing very carefully the various results which have been obtained in efficiency tests of arc and incandescent lamps, gas flames, and other ordinary sources of artificial illumination, Prof. Nichols briefly pointed out what must be considered as the limiting efficiences which could be obtained from these sources of illumination. The lecturer then considered several other and, at present, uncommon sources of artificial light, to which he and his colleagues in the Cornell University have recently given considerable attention. The most important of these he considered to be magnesium, and he briefly reviewed some very promising results as to its efficiency which he has recently obtained. In the discussion of the Paper, Mr. Tesla called attention to some interesting experiments which he had made by the mixture of a solution of chloride of magnesia with finely powdered carbon. The resulting paste was pressed into a pencil suitable for an arc light, and gave some interesting results when burned. He had also experimented with incandescent carbon filaments, in the structure of which the same material had been intimately incorporated.

## BOOKS, &c., RECEIVED.

"Kalender für Elektrotechniker, 1891." Edited by F. Uppenborn. (Munich and Leipszig: R. Oldenburg.)

"The Electric Light Popularly Explained." By A. Bromley Holmes. (London: Bemrose and Sons.) Price 1s.

"Spinning Tops" (Romance of Science Series). By Prof. J. Perry, F.R.S. (London: Society for Promoting Christian Knowledge.) Price 2s. 6d.

"Soap Bubbles" (Romance of Science Series). By Prof. C. V. Boys, F.R.S. (London: Society for Promoting Christian Knowledge.) Price 2s. 6d.

## LEGAL INTELLIGENCE.

### Queen v. Fareham Electric Light Company and Others.

In the Queen's Bench Division on Monday last, before Mr. Justice Stephen and Mr. Justice Charles, sitting as a Divisional Court,

Mr. B. SMITH moved on behalf of the Defendants in the case of the Queen v. The Fareham Electric Light Company and Others, for a rule absolute, removing the trial of an indictment found against them at the last Winchester Summer Assizes into the Queen's Bench Division.

The learned Counsel said that as two sets of the Defendants were corporate bodies, he was entitled to a rule absolute.

Their Lordships granted the application.

### Lane Fox v. Drake and Gorham.

This was an action in the Westminster County Court by the plaintiff, Mr. Lane Fox, to recover ten shares in the Lane Fox Electrical Company, which shares, he alleged, were being wrongfully withheld by the defendants, Messrs. Drake and Gorham, electrical engineers, of Victoria-street, Westminster.

It appeared from the opening of counsel for the plaintiff, that Mr. Lane Fox gave the defendants ten shares in the Electrical Company in consideration of certain services rendered. It subsequently came to the knowledge of the plaintiff that both the defendants were, in common with other firms, infringing the very patents for the sale of which the company was formed. That being so, the plaintiff thought they were undesirable people to be directors of his company, and offered them £30 if they would transfer the shares back to him. They agreed to do so, but ultimately a disagreement arose, and they refused to part with their shares. The action was now brought for specific performance of the agreement.

At this stage of the case the learned counsel on both sides held a consultation, which resulted in the case being withdrawn from his Honour's list by consent, each party agreeing to pay their own costs.

**Re Henry Thompson.**—A receiving order was made in October against this debtor, he being described as of Gresham-street, Gray's-inn-road, and St. Peter-street, Islington, electrical case and cabinet maker. The summary of accounts has just been issued by Mr. Wildy, Official Receiver, showing unsecured debts £3,679, and assets £860. 14s. 4d. The debtor, an accountant and general business agent, in 1886, became manager of his present business, which he eventually purchased, with the assistance of a partner, who brought in about £2,800, and carried it on as the "Eclipse Cabinet Works" and the "Eclipse Electrical Case Works." The partner afterwards retired, upon terms which were not carried out. The Official Receiver reports that the debtor admits having been insolvent for the last ten years, and that he attributes his deficiency to loss on trading, owing to bad debts and falling off in business, to his household and personal expenses, to interest on borrowed moneys, and to other causes. Mr. Percy Ravencroft, accountant, 10, Cheapside, is the trustee of the estate.

## TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning.*]

TENDERS WANTED.—As will be seen by our advertisement columns, persons willing to purchase india-rubber and gutta-percha core may obtain conditions of the contract from Mr. A. Abercrombie Jopp, Director-General of Stores, India Office, Whitehall, S.W., to whom tenders must be sent not later than 2 p.m., on Tuesday, the 16th inst.

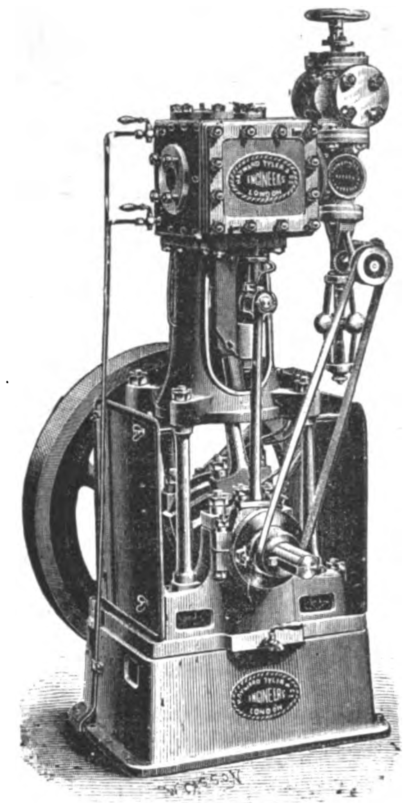
———The Corporation of Nottingham, having obtained a Provisional Order for supplying electricity in the Borough of Nottingham, and having power with the approval of the Board of Trade to transfer their powers, duties, and liabilities to any company or person, request such companies or persons as would be prepared to contract and find the necessary capital for working the order under a transfer of the powers and liabilities of the Corporation to send their names and addresses to Mr. S. G. Johnson, town clerk, Guildhall, Nottingham, on or before December 15, 1890. Further particulars will be found in our advertisement columns.

———Tenders are required by the North-Eastern Railway Company for the supply of telegraph apparatus and telegraph wire and line stores during the six months ending June 30, 1891. Forms of tender may be obtained of Mr. Graves, Telegraph Department, York, and Tenders must reach the Secretary of the Company by noon on the 9th instant.

PLANT FOR SALE.—Our advertisement columns contain particulars of an electric lighting plant for sale, comprising a 50-volt dynamo, large switch-board, 75 switches, voltmeters, Wheatstone bridge, about 100lb. of 5·2mm. platinoid wire, pulleys, leather and camel-hair driving belts, and four marine countershafts.

Digitized by Google

VERTICAL HIGH-SPEED ENGINE.—Messrs. Hayward, Tyler and Co., of London and Luton, have constructed a single-cylinder double-acting high pressure non-condensing engine, which is illustrated herewith. The cylinder is carried on a casting forming the guides, and this is supported on four mild steel columns. The cylinder is 7½in. diameter, and has a stroke of 7in. It is made of the hardest workable cast iron, and is tested to 250lb. per square inch. The piston is of cast iron, very deep, and fitted with Ramsbottom rings. The governor is of the high-speed type, acting directly on a double-beat perfect equilibrium throttle-valve, and is so constructed as to have no joints. It is adjustable whilst running. Two lubricating boxes are fitted in suitable positions, so that by means of copper pipes the oil is carried to every bearing. Special means of carrying the oil from the lower ends of the pipes to the bearings are adopted, so that the whole can be oiled while in motion, and thus



obtain constant running if necessary. Splash-plates are provided for the back and front of the engine, provided with wing nuts for easy removal, and arranged so that the whole of the oil drips into the oil channel. The crank pin in the bed-plate drains through a pipe into the general oil channel, and a gun-metal cock is provided for drawing off the oil from the channel as need be. A speed of 350 revolutions per minute is considered to be the best, but the engine will run without trouble at 450 if desired.

MESSRS. DICKINSON & CO.—This firm have just secured from Mr. Norman Forbes a contract to install the electric light throughout the Globe Theatre.

FIRE.—Shortly before three o'clock on Saturday afternoon last a fire occurred on the premises of Messrs. Gent and Co., electricians, Bede-street, Leicester. Very little damage was done, and no hindrance to business was occasioned.

REMOVALS.—Messrs. Lacombe & Co. announce that, in consequence of increase in business, they have removed to 7, Carteret-street, Queen Anne's-gate, Westminster, where a stock of carbons, &c., will be kept.——Mr. Joseph Coles, electrical engineer, announces that he has removed from 1, Barlborough-street, New Cross, London, S.E., to larger premises at 840, Old Kent-road, S.E.

KELWAY'S ELECTRIC LOG SYNDICATE (LIMITED).—The liquidator (Mr. R. Alabaster) announces that a meeting of the shareholders of this syndicate will be held at his office, Leadenhall-buildings, 1, Leadenhall-street, E.C., on December 19th, at 3 p.m., to receive his report as to the liquidation.

## PATENT RECORD.

### APPLICATIONS FOR PATENTS.

NOTE.—*The undermentioned applications are not open to public inspection until after the acceptance of the complete specification. The names within parentheses are those of communicators of inventions.*

November 21, 1890.

18,896. A. S. ELMORE. London. Improvements in the process and apparatus for manufacturing copper tubes, sheets, strips, and wires by electrolysis.

18,904. H. J. O. FRASER. London. Improvements in magneto-electric telephonic apparatus.

18,910. C. F. JOSZ. London. Improved apparatus for stopping machinery by electricity.

18,913. E. L. JOSEPH. London. An improved electrical switch.

18,916. H. ARON. Liverpool. Improvements in, or appertaining to apparatus for measuring electric currents.

18,926. F. SUISSE. London. Improvements in electric arc lamps.

November 22, 1890.

18,969. W. A. PRICE and W. E. GRAY. London. An improved apparatus for measuring the resistance and insulation of electric conductors

18,993. N. PROKHOROFF and N. FAHLBERG. London. Improvements in and relating to electric clocks.

November 24, 1890.

19,033. WOODHOUSE and RAWSON. London. Improvements applicable to switches used for electrical purposes (A. W. J. Hinde, Australia)

19,034. R. J. JONES and WOODHOUSE and RAWSON. London. Improvements in automatical electrical apparatus.

PATENT

SILICIUM BRONZE AND SILICIUM COPPER WIRE.

The best for overhead Telephone and Telegraph Lines,

AND ALL ELECTRICAL PURPOSES.

Hard Drawn High Conductivity Copper Wire.

ROLLED AND DRAWN PHOSPHOR BRONZE.

PHOSPHOR BRONZE VULCAN PHOSPHOR DURO METAL

PHOSPHOR BRONZE BEARINGS, BUSHES, AND OTHER PARTS OF ELECTRICAL MACHINERY.

*SOLE PROPRIETORS of the British, Indian and Colonial Patents,*

THE PHOSPHOR BRONZE COMPANY (Limited),

*87, Sumner Street, Southwark, London, S.E.*

WIRE AND SHEET MILLS: BAGOT STREET, BIRMINGHAM.

Digitized by Google

19,035. F. W. Dodd. London. Improvements in dynamos for firing explosive charges, or for medical purposes

19,037. J. S. Gisborne. London. Means of neutralising or controlling the polarity of iron or steel for the protection of magnetic needles from local attraction.

19,049. F. L. Muirhead. London. Improvements in electric lighting appliances for photographic and other purposes.

19,052. M. N. Mallison. London. Improved combination of ingredients constituting a compound as an illuminating medium for electric incandescent lamps.

19,057. W. P. Thompson. Liverpool. Improvements in electric arc lamps (R. H. Beach, United States).

19,068. J. E. Kingsbury. London. Improvements in telephone spring-jack switches (The Western Electric Company, United States).

19,076. W. M. Mordey. London. Improvements in electric safety fuses.

November 25, 1890.

19,079. J. Armstrong. Bilston. Electric cables.

19,097. A. M. Clark. London. Improvements in, and in the method of, manufacturing incandescent electric lamps and other exhausted receivers (A. Bornholdt and J. Glatz, United States).

19,108. C. Adams-Randall. London. Improvements in, or connected with combinations of hydraulic, pneumatic, and electric means for obtaining, transmitting, and applying motive power.

19,155. H. H. Lake. London. Improvements in electrical storage batteries or accumulators (G. E. Hatch, United States).

19,162. M. W. Dewey. London. Improvements in methods of electric welding and metal working.

19,191. M. Whelass and J. E. Wheatley. London. Improvements in and relating to underground electric tramways.

19,203. L. Hausmann. London. Improvements in the manufacture of thin metal tubes by electrolysis.

November 26, 1890.

19,234. H. C. Swindell. Birmingham. A method of and apparatus for controlling gas-lighting in cases of failure of electric light installations.

19,239. H. Barton. London. Improvements in electric switches.

19,272. C. E. Carpenter. London. Electric soldering irons. (Date applied for under Patents Act, 1883, Sec. 103, 10th May, 1890, being date of application in United States).

## SPECIFICATIONS PUBLISHED.

1890.

58. Gardner. Incandescent electric lamps. (Price 6d.)

761. Dahl. Generating electricity. (Price 8d.)

2,255. Macaulay. Cruikshank (Schwabacher). Electric switches, etc. (Price 8d.)

5,062. Depoele. Electric Railways. (Price 8d.)

14,269. Radcliffe. Electrical signalling. (Price 8d.)

15,006. Kennedy. Converting electrical energy. (Price 6d.)

15,469. Imray. (The Bethel Electric Medical Baths Company, Limited). Administering electricity to the human body. (Price 6d.)

## NEW COMPANIES REGISTERED.

**HORSHAM IRONWORKS (LIMITED).**—Registered by Waterlow Brothers and Layton (Limited), 24 and 25, Birchin-lane, E.C., with a capital of £5,000 in £5 shares. Object: To acquire the business of Steele and Dodson, of Horsham, engineers and machinery agents, &c.

**THE SOUTH INDIAN RAILWAY COMPANY (LIMITED).**—Registered by Freshfields and Williams, 5, Bank-buildings, E.C., with a capital of £1,000,000 in £10 shares. Objects: (1) to enter into and carry into effect, either with or without modification, an agreement, the form of which is set forth in the schedule to the articles of association of the Company; (2) from time to time to divide among the members of the Company any interest received from the Secretary of State for India in Council under the provisions of the said agreement; (3) to purchase, take on lease, or otherwise acquire or accept permission to use any railway, tramway, roadway, lines of telegraph and telephone, or other mode of general communication, or any interest in any of the same.

**SLEEMAN CONTROLLED TORPEDO SYNDICATE (LIMITED).**—Registered by H. Y. Dickinson, 56, Gray's Inn-road, W.C., with a capital of £12,000 in £1 shares. Object: to carry on the business of manufacturers and dealers in torpedoes.

**WEYMERSCH ELECTRIC BATTERY SYNDICATE, LIMITED.**—Registered by Harwood and Stephenson, 31, Lombard-street, E.C., with a capital of £20,000 in £5 shares. Object, to carry on in the United Kingdom and elsewhere the business of an electric light company in all its branches. The first subscribers of one share each are:—A. M. Cardwell, 29, St. James-street, Piccadilly; H. Weymersch, 17, Glengarry-road, Dulwich; W. S. T. Martin, 17, Melbourne-grove, Dulwich; E. C. de Segundo, 7, Victoria-street, S.W.; F. Fanta, 10, Moorgate-street; C. F. Jones, Inglewood, Upper Norwood; Mrs. McKenzie, 21, Talbot-road, Bayswater. There shall not be less than three nor more than five directors. The first are the first two signatures and T. H. and W. A. Cardwell. Qualification, £500. Remuneration to be determined in general meeting.

## CITY NOTES, &c.

**BRAZILIAN SUBMARINE TELEGRAPH COMPANY.**—The Directors of this Company have declared an interim dividend of 3s. per share, or at the rate of six per cent. per annum, free of income-tax, for the quarter ended September 30th last, and payable on the 23rd inst. The books of this Company will be closed from the 16th to 22nd inst., both days inclusive. The receipts of this Company for the past week amounted to £6,368.

**COMMERCIAL CABLE COMPANY.**—At a meeting of this Company, held on Wednesday, it was decided to increase the quarterly dividend, payable on January 1st, to 1¾ per cent. The Company also decided to pay £120,000 in distribution to the bondholders.

**CUBA SUBMARINE TELEGRAPH COMPANY.**—The estimated traffic receipts of this Company for the month of November were £3,100, as compared with £3,112 in the corresponding month of last year. The receipts for the month of August, estimated at £2,900, realised £2,913.

**EASTERN TELEGRAPH COMPANY, LIMITED.**—The traffic receipts of this Company for the month of November, 1890, amounted to £58,975 as against £60,578 for the corresponding period of 1889, or a decrease of £1,603.

**EASTERN EXTENSION TELEGRAPH COMPANY.**—The receipts of this Company for November amounted to £44,742, as against £44,147 in the corresponding period, showing an increase of £595.

**FOWLER-WARING CABLES COMPANY (LIMITED).**—The second ordinary general meeting of this Company will be held at Winchester House, Old Broad-street, E.C., this day (Friday) at 12 noon.

**GREAT NORTHERN TELEGRAPH COMPANY.**—The traffic returns of this Company are as follows:—Receipts in November, 1890, £23,600; 1st January to 30th November, 1890, £256,400; corresponding months, 1889, £252,400; corresponding months, 1888, £250,200.

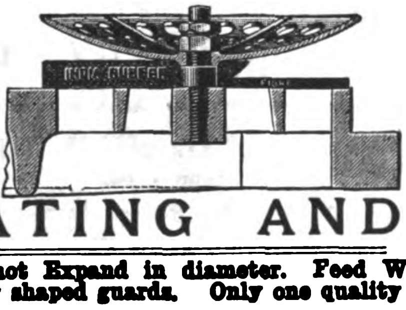
**WESTERN AND BRAZILIAN TELEGRAPH COMPANY.**—The traffic receipts of this Company for the week ending November 28, 1890, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £5,016.

**WEST COAST OF AMERICA TELEGRAPH COMPANY.**—The traffic receipts of this Company for the month ending November 30, 1890, amounted to £4,350.

**WEST INDIA AND PANAMA TELEGRAPH COMPANY (LIMITED).**—The estimated traffic receipts for the half-month ended Nov. 30th were £2,807, against £3,111 in the corresponding period of 1889, or a decrease of £304.

NEW VALVE

No Rubber, Percha, or Leather.



One-half the price of Rubber or Metal.

FOR CIRCULATING AND AIR PUMPS.

Unaffected by any Lubricating Oils. Does not Expand in diameter. Feed Water may be worked at any temperature Suitable for any shaped guards. Only one quality manufactured.

"12, John-street, Sunderland, 26th Sept. 1886.

"DEAR SIRS,—In reply to your letter of the 25th inst., the Valves I got from you have done their work well, and ARE AN UNQUALIFIED SUCCESS. I will continue to get them from you as required.—Yours faithfully, JAMES WESTOLL."

For further Testimony and Prices, apply to MOSSES & MITCHELL, 68-71, Chiswell Street, London.

# THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 656.—Vol. XXVI. FRIDAY, DECEMBER 12, 1890. Price Fourpence.

## NOTES.

A Paper of great interest and importance was read by Mr. Frank Bailey at the Society of Arts on Wednesday last, on "The Electric Lighting Progress in London." He gave a number of statistics of great value, based on a considerable experience. Mr. Bailey finds that the ratio of the maximum number of lamps lit at the time of heaviest load is about one-half of the whole number wired, and he gives the figures relating to their proportion, as experienced by the principal supply companies. Figures relating to the life of lamps of different sizes, and different voltages were given, and though some of these referred to old-fashioned lamps, we congratulate the author on having brought forward the great importance of keeping records of lamp life, and of adding to our general knowledge on this important question.

It was agreeable to find the engineer of the formidable rival to the London Electric Supply Corporation expressing his regret at the hard things that are being said against it. Mr. Bailey acknowledged frankly that we owe a debt of gratitude to the enterprise of Lord Crawford, who recommended the use of alternate current distribution at the Grosvenor Gallery, which was the first serious central station in London, and which at first gave wide satisfaction, as is amply proved by the very fact that their failures were due to the overloading of their plant when they were unhappily induced by a clamouring *clientèle* to connect them up to their overhead circuits. The resulting breakdowns have injured the Corporation to an extent which might be guessed by the shareholders, but they have injured the progress of electric lighting in this country to an extent which it is impossible to estimate.

These greatly abused overhead wires came in for a share of Mr. Bailey's sympathy. He reminded his hearers that with twenty-five miles of overhead wires in London not one single accident has happened which was directly attributable to them or the current which they carried. The prejudice, *pace* the æsthetic question, has been solely due to the accidents which have occurred, owing to the criminal carlessness of the work, in New York.

Mr. Crompton asserted at the Society of Arts on Wednesday that he designed and was ready to build central stations many years ago, the only one actually begun being that which now lights Victoria Station, and that he was then as well able to do so as he is at present. In making this rather startling statement, it must be remembered that he is alluding to low pressure distribution. Transformers were in those days as unheard of as Crompton-Howell batteries. Large dynamos were not made, and the special difficulties which have been found to arise from cross-induction were unknown. We venture to express some satisfaction that many schemes which were propounded then never reached the scale of twelve inches to the foot. The British public will stand a good deal, but it would not put up with the "pioneering" work of our American cousins.

The question raised by Mr. Richard Chamberlain in the House of Commons with reference to the Chelsea Electricity Supply Company resolves itself into the estimation of the accuracy of two assertions. He complains, in the first instance, that the light was bad. This is largely a matter of taste, some people prefer to overrun their lamps. But he refers to the indications of a voltmeter, and as the Board of Trade Standardising Laboratory is not yet open, and its volt is not yet legalised, it is obviously premature to press for any remedy. It might, indeed, be better to take the more circuitous course of a photometric determination of the candle-power of the lamp, seeing that we have a barbarous unit of light called a standard candle, but the lamps are sold under no warranty, and the lamp makers would be as powerless as is Mr. Chamberlain to come to any sound conclusion. Mr. Bailey, in the course of his most interesting Paper at the Society of Arts on Wednesday, seriously suggested that voltmeters might be calibrated by photometric measurement of glow lamps, so great is the accuracy with which they are made. The legalisation of the volt is, we believe, merely waiting for certain resistances. These are being leisurely compared with the standard coils, and we can only hope the results will be comparable with the time bestowed upon them.

It is not surprising that some complaint is made about the variation of 4 volts in 100 which is allowed by the Board of Trade, since the resulting variation of light is so considerable, but it must be observed that no other consumers in the Chelsea district are making any serious complaint—indeed, we have seen some most flattering testimonials as to the excellence of the supply—and it is evident, where batteries are used, and used so extensively as at Chelsea, that no sudden or serious fall of pressure is to be apprehended, such as might be felt on a circuit where the voltage is dependent directly on the speed of the dynamos which may be checked by a sudden demand. Mr. Richard

Digitized by Google

CHAMBERLAIN is undoubtedly very rash in adducing the evidence of a voltmeter when no legal volt exists, and his case is very ill-supported since he gives no idea of the accuracy of calibration of his instrument.

OF a different order altogether is the complaint of various firms who have suffered by the breakdown of the transformer station at the Grosvenor Gallery. Many of them imagine that the generating station from which they received their current has been destroyed; it is freely but erroneously asserted that the trouble has been due to the use of high-pressure or to the novel construction of the mains. Our readers have been informed of the exact cause, and will not be surprised to hear that so far from there being any anxiety to recommence the supply with undue haste, it has been proposed to defer it until the beginning of next month; the importance of thoroughly substantial work, the completion of which is merely a matter of time, being greater than the attempt to satisfy the immediate demands of the consumers.

THE result of the actions Watt *v* Maxim Electric Company and Maxim Electric Company *v.* Watt, a report of which is to be found in another column, will not prove pleasant reading to those who still cling to the belief that the hocus-pocus electrical finance of 1882-83 is entirely safe and highly remunerative. The one solitary good feature of the Electric Lighting Act of 1882 was that it saved the public from the rapacity of those who would have multiplied such companies as this. The electro-financial methods of that period were an unmitigated evil, and if investors still regard electrical enterprises with some suspicion, which, let us hope, has now no foundation in fact, it is due to their losses of seven years ago.

WHAT the electro-financial style of 1882-83 actually was when a Company got beyond the promotion stage, we are reminded by the lawsuits referred to above. In September, 1883, the Maxim-Weston Company obtained the services of a managing director at a salary of £600 per annum, plus 5 per cent. commission on net profits. In February, 1886, a time, be it remembered, when electric lighting in England was at its lowest ebb, this salary was increased to £1,000 per annum, with an annual increment of £100 up to £1,200 a year. Such valuable management could not obviously confine itself to ordinary modes of profit making, and the SOLICITOR-GENERAL had an easy task in proving his assertion that no genuine profits at all were earned between 1883 and 1887. Profits, however, were shown. Electrical plant was sent on sale to such active markets as Mauritius, and its invoice value was brought into the profit and loss account as cash. Patents were kept up in the books at their original values, and occasionally increased in value. Old stock was equally rejuvenescent. For example, "One clock, superior, £2," suddenly became "One clock, superior, £3 10s."; and vices, lathes, atmospheric-engines, dynamos, &c., all followed suit. With so remarkable a book-keeper is it surprising that the Maxim Electric Company has ended its existence "in liquidation" (whither are bound all similarly-conducted businesses), and that it has been found advisable for the late Managing Director to hand back £1,000 to the Company, and to pay its costs.

IT is surprising that while so much time has been devoted to rendering the dynamo highly efficient, the problem of the most economical method of distributing light for illuminating purposes has been so little studied. A difference of a few per cent. in the efficiency of two dynamos is regarded as important, while a much greater variation in the efficiencies of two electric lamps is altogether ignored. Yet it is obvious that the cheapness of a system of electric lighting is as dependent on the latter as the former. The investigation of Mr. LOPPÉ, an abstract of which we publish in another column, is interesting in connection with this subject, although it may be argued that the condition of most uniform illumination is not exactly what is wanted for practical purposes. It is no doubt, to a great extent, true for house lighting; and as in this case glow lamps are employed whose height from the ground approximates to their distance apart, the illumination is a maximum between the lights and is fairly uniform all over the room lighted. For street lighting the lamps are, however, placed much farther from each other than from the ground, and the illumination half-way between them is a minimum. Whether this minimum should be as near the average as possible is a questionable point. Mr. LOPPÉ assumes that the power required to produce a light varies as the candle-power of the light produced. This, of course, is unjustifiable, except as a simplification, but the truth of his results are not all dependent on this assumption. In determining the best height of lamp the candle-power is assumed fixed, so that the cost of the light, which depends only on the candle-power, is in this case constant, and the expression given for the height is still correct.

WE understand that the City and South London Railway will not be opened to the public on Monday next, as has been announced by a news agency.

**Society of Engineers.**—The annual dinner of this society was given at the Holborn Restaurant on Wednesday last.

**The Direct United States Cable Company.**—We have received a handsomely illustrated chart of this company's working.

**Reduction of Telephone Rentals.**—The annual subscription to the Belfast Telephone Exchange is to be reduced from £15 to £10.

**Leeds.**—The Corporate Property Committee has at last resolved to take steps to arrive as near as can be at the actual cost to the Corporation of electricity per lamp per hour.

**Electric Tanning in America.**—The American Tanning Company of New York has just been organised, and is now introducing the Worms and Balé process of electric tanning.

**Exeter.**—At a special meeting of the Exeter Town Council on Wednesday last it was decided, after nearly two hours' discussion, by 24 votes to 12, to apply for a Provisional Order.

**Newcastle.**—A special meeting of the Newcastle City Council was held on Wednesday last week for the purpose of considering whether the Council should consent to an application by the Newcastle and District Electric Lighting Company for a Provisional Order. Assent to the application of the company was refused by 37 votes to 10.

Digitized by Google

**Telephonic Communication with Lighthouses.**—Henley's Telegraph Works have recently manufactured a submarine telephone cable which has been laid between Hanzo, the most southern point of Finland, to a lighthouse 2½ miles from the coast.

**The Calais Submarine Cable Works.**—The new submarine cable works at Calais belonging to the Sociéte Générale des Téléphones are to be opened in the course of the present month in the presence of several representatives of the French Government.

**Royal Society.**—The members of the Royal Society intend raising a fund for the purpose of adding to their Gallery a portrait of Sir Gabriel Stokes, Bart., M.P. Sir John Lubbock, Bart., M.P., Sir Fred. Abel, and Sir Lyon Playfair are acting on the committee formed to arrange the preliminaries.

**The Electro Harmonic Society.**—A very agreeable evening was spent on Monday last by the members of this society and their lady friends at the St. James's Hall Restaurant, the enjoyment of the evening being more especially due to the instrumentation of Mr. T. E. Gatehouse and the singing of Mrs. Alexander Siemens, to both of whom a very hearty reception was accorded.

**Electric Traction at Southington, Conn.**—The smallest town in the United States which has an electric street railway in operation is Southington, Conn., with a population of 5,400. The cars are in service over two miles of track, and the average daily receipts are $9 per car. The power for the operation of this road is furnished by the local lighting company, and costs $1.25 per car per day.

**Lewes.**—The poll at Lewes on the electric light question was a complete failure. Only 329 ratepayers recorded their opinion. Of these the supporters of gas mustered 177, and electricity found favour in the eyes of 152 voters. The result is a majority of 25 in favour of gas, but the decision can scarcely be considered a final one, seeing that some 1,500 other persons remained neutral.

**Electric Motors in Mills.**—According to figures accredited to a New England cotton mill engineer of high reputation, says the *Electrical Engineer*, of New York, eight modern mills, with first class shafting, show that on the average 28·7 of the total horsepower is expended in driving the shafting. In one instance, to drive the shafting alone took 36·1 per cent. of the whole horsepower, and in another 39·2. The conclusion naturally arrived at by our contemporary is—why not employ electric motors?

**High Discharge Accumulators.**—The Electric Construction Corporation are now making a modified form of storage cell known as the K type, capable of giving a greatly increased rate of discharge. Taking the rate of discharge of the new K cell at 100, the comparative rates of discharge for the T (traction) and L (lighting) cells for equal plate area are respectively 70 and 47. The makers expect the new cell to have as long if not a longer life than previous types, and are of opinion that double the list rate of discharge can be maintained for short periods, say half an hour, without injury to the cell.

**The London Electric Supply Corporation and its Customers.**—Messrs. Mappin, Brothers, of Regent-street, in a letter to the *Times* of Monday, indignantly complaining of the recent electric lighting breakdowns, conclude as follows:—

"We think that you and a number of your readers will agree with us that it is a monstrous thing that any licence should be granted to a corporation professing to supply the public with what it so obviously does not possess or cannot control, and we write this in the interest of a large section of the public who might be (as we have been) put to great expense and enormous inconvenience owing to what can only be described as (to put it mildly) the utter incapacity of such electric lighting companies."

**Electrical Litigation.**—An action has been brought by the Electrical Supply Company of Chicago against the Great Western Electric Supply Company of the same city, to prevent the latter Company from using the name "Electric Supply" as a part of the title of the Corporation. The plaintiff Company alleges that it was the first Company in the United States to adopt the name "Electrical Supply," since which time it is asserted it has become popular, and a confusion which is detrimental to the Electrical Supply Company has resulted. It is stated that other actions will be commenced against other companies using the words "The Electrical Supply."

**An Electrostatic Experiment.**—At a recent meeting of the Académie des Sciences, M. Zenger described an interesting piece of apparatus devised to illustrate his theory of the electrodynamic rotation of the planetary bodies. A hollow glass globe, the inside of which is silvered, is placed midway between the poles of a Wimshurst machine, care being taken, however, that the line joining the centres of these terminals does not pass through the centre of the globe. When the Wimshurst machine is operated, the globe revolves on its axis at a speed governed by the speed of the handle of the machine. The globe must be kept several centimetres away from the discharging terminals to prevent sparking.

**Variations of Conductivity under Different Electrical Influences.**—In a paper on this subject read recently before the Académie des Sciences, M. Ed. Branly stated that if a circuit be formed with a Daniell's cell, a high-resistance galvanometer, and a very thin layer of copper deposited on a ground glass or ebonite plate, 7cm. long and 2cm. wide, only an insignificant current passes. An abrupt diminution of resistance is experienced, however, when electric discharges, from a Wimshurst machine or a Ruhmkorff's coil, are produced in the neighbourhood of the circuit. The action diminishes as the distance of the sparking apparatus increases, but it may be very easily observed, without special precautions, at several metres.

**The Bernados Welding Process.**—Sir Douglas Galton, Mr. W. H. Preece, Mr. Ashton (of the Royal Laboratory, Woolwich), and other gentlemen visited Messrs. Lloyd and Lloyds' Coombs Wood Tube Works on Friday last for the purpose of inspecting experiments in electric welding. The process used is that known as the Bernados process, which was fully described in the *Electrician* of November 25, 1887, the sole right to the use of which has been acquired by Messrs. Lloyd and Lloyd, and the welding is affected by means of an arc. Messrs. Lloyd and Lloyd have already applied the process in the manufacture of various articles in current demand, and they are also experimenting with it in other directions. The visitors expressed themselves most favourably as to the achievements and possibilities of arc welding.

**Electric Welding.**—Sir Douglas Galton, K.C.B, Mr. W. H. Preece, F.R.S., Mr. Ashton (of the Royal Laboratory, Woolwich), and other gentlemen visited Messrs. Lloyd and Lloyds' Coombes Wood Tube Works on Friday last for the purpose of inspecting their installation of electric welding. The process used is that known as the Benardos process, the sole right to the use of which has been acquired by Messrs. Lloyd and Lloyd, and the welding is effected by means of the arc. The firm have already applied the process in the manufacture of various articles in current demand, and are also experimenting with it in other directions. They have purchased the engines used for electric lighting at the French Exhibition in order to drive a larger installation which they are now completing. The visitors expressed themselves most favourably as to the possibilities of arc welding.

**Cable Extensions.**—A fourth cable has now been laid by the Eastern Telegraph Company from Suez to Aden, a distance of 1,400 miles, and by May next a third cable will be laid from Aden to Bombay, a distance of close on 2,000 miles. The Eastern Extension has duplicated its cable from Madras to Penang, which are 1,500 miles apart. There are now three cables between London and Australia. Besides these extensions, negotiations are in progress for the laying of a cable to connect Madagascar and the Mauritius with the Eastern and South African Company's cable at Zanzibar.—On the coast of South America the Western and Brazilian Company are doubling the line from Rio de Janeiro to Buenos Ayres; and nearer home we have just had 600 miles of new cable laid for the Great Northern Company between the North of England and Sweden.

**Technical Education in Manchester.**—At the recent annual meeting of the Manchester Technical School, it was resolved that its property, effects, and liabilities should be transferred to the Manchester Whitworth Institute. The Governors, says

Digitized by Google

*Industries*, wisely recognise that it is not quantity but quality which must be their chief concern. This they will be able to provide for under the scheme of incorporation. Our contemporary understands that the aim is to raise £100,000 for building purposes alone. Under the Technical Instruction Act the Town Council of Manchester has raised £4,000 for this year, and half of this has been allotted to the Technical School. The Governors are, therefore, justified in their hope that in a very short time there will be established and equipped in their city a technical school worthy of the greatest industrial centre of the world, a school which shall be made directly and readily accessible to the fit and capable of every class.

**Air Resistance at High Speeds.**—Some experiments on the resistance of trains on railways recently carried out on the State railways of France, and a brief account of which appears in the abstracts of foreign papers prepared by the Institution of Civil Engineers, bring out very clearly amongst other things the great importance at high speeds of the reaction of the surrounding atmosphere, the greater portion of which applies directly to the locomotive, the resistance of which, with high speed trains, amounts frequently to more than half the total resistance. Two engines, of which the resistance was measured separately and found to be 19·8lb. per ton at 37 miles per hour, were coupled together and again tried. The resistance fell to 14·31b. per ton; the second engine was masked by the first. It may be argued from this that by a suitable adaptation of the front of a locomotive, electrical or otherwise, a saving of from 8 to 10 per cent. of the effective power could be made.

**Electrical Cars on Heavy Gradients.**—In a Paper on "Street Railways," recently read before the Chicago Electric Club, Mr. T. P. Bailey remarks that among the numerous objections raised to the use of electricity in street car propulsion was that grades exceeding 5 per cent. could not be mounted. But experience, he says, has shown that grades as high as 14 per cent. can be ascended with safety and satisfaction. There is a grade of 13·2 per cent. on the street railway at Lynn, Mass., over which run 16ft. cars equipped with two 15 horse-power motors. At Milwaukee there is a grade of 10·3 per cent. successfully operated over by 20ft. cars, equipped with two 15 horse-power motors. A similar grade is met with at Newport, R.I., and Omaha, Neb., and numerous grades almost as heavy are seen in the electric railway systems at Des Moines and Davenport, Iowa, and Kansas City, Mo. The tendency, says Mr. Bailey, at the present time is in the direction of longer cars, double trucks, and heavier motors.

**Expiration of the Telephone Monopoly.**—On Monday night, in the House of Commons, Dr. Cameron asked the Postmaster-General whether, in view of the fact that the patent for the telephone in use by the company which possessed a practical monopoly of telephonic communication in Great Britain had now expired, and in view of the numerous complaints on the part of the public as to high rates and faulty service resulting from that monopoly, he would, with as little delay as possible, make known his decision as to applications for licenses submitted to the Post Office by proposed competitors desiring to introduce loud-speaking and long-distance telephones, and other forms of improved instruments. In reply, the Postmaster-General said he hoped to be able at an early date to announce the decision of the Government with regard to licenses for telephone exchanges. It should, however, he said, be borne in mind that the more important patents have not expired, and do not expire until July next.

**Paddington Vestry.**—At the last meeting of this Vestry, Mr. Fardell moved the following motion, "That as the draft agreement put forward by the Metropolitan Electric Supply Company under Clause 2, provides that 'either party may determine this agreement on giving three months' notice to the other,' it be referred to the Electric Lighting Committee to consider, in conjunction with the Vestry solicitor, and report to the Vestry at its next meeting, whether such agreement is in accordance with the provisions of the 'Electric Lighting Orders Confirmation (No. 12) Act, 1890,' inasmuch as that Act, while granting a monopoly to the above Company, expressly reserves the right to be supplied with electric energy to every owner and occupier, a right which the above cited agreement curtails." It was decided to leave the whole question in the hands of Colonel Barchard and Colonel Blair to write to the Company, and to report as to the result of the same.

**Electric Light Beacons.**—The United States Lighthouse Board, says *Iron*, is considering the feasibility and advisability of placing electric light beacons upon several of the new lightships to be stationed along the Atlantic coast. It was originally intended to equip these vessels with the best modern lights which could be obtained, the lenses and lamps to be of the highest order. It is thought possible, however, to obtain a better light by the use of electricity, in which case it would be desirable to equip the new lightship which is to be placed at Sandy Hook and one or two others with the electric light. In order to ascertain if the benefits which an electric beacon may possess over the regulation lamps will justify the additional expense, the Lighthouse Board will soon commence a series of experiments to be conducted at the lighthouse station on Staten Island. It is also proposed to equip two or three of the new lightships with flash lights, to be produced by means of revolving shades. The system of electric lights now in use on the buoys in Gedney's Channel, in New York Bay, is reported to give perfect satisfaction.

**Copper.**—Much satisfaction, says the *Statist*, has been expressed by persons interested in securities of copper mining undertakings at the statistics relating to the position of copper. For over eighteen months we have had a continual drain upon stocks, in consequence of the consumption exceeding the supplies. . . It is noticeable that for twelve months past to the end of November, and with consumption increasing about 30 per cent. over the corresponding twelve months, there has been no increase in supply such as might have been expected:—

| 12 months to end of Nov. | Supply. Tons. | Consumption. Tons. | Excess of supply. Tons. | Excess of deliveries. Tons. |
|---|---|---|---|---|
| 1890 | 110,664 | 145,208 | — | 34,544 |
| 1889 | 114,173 | 112,095 | 2,078 | — |
| 1888 | 123,587 | 70,802 | 52,785 | — |

According to Messrs. H. R. Merton and Co.'s statistics the copper stocks at the end of November amounted to 65,410 tons, against 99,984 tons this time last year. The supplies for November, 1890 and 1889, were respectively 8,415 and 9,859 tons, the deliveries 11,230 and 13,415 tons, and the prices £55⅜ and £50⅛ per ton.

**Aluminium Trolley Wheels.**—Aluminium trolley wheels are now being introduced in the States. Their total weight is only about two pounds, a great advantage, meaning lighter trolley poles, lighter springs, less danger of breaking down, and far less upward pressure against the wire necessary to produce good contact. Several of these trolleys (says the *Electrical World*) were exhibited at the Buffalo meeting of the American Street Railway Association last month, and scored a great hit. The construction of this trolley is in some respects peculiar. The wheel is fastened permanently upon a steel axis which revolves in the bearing. These are not metallic, but are formed of a thick lignum-vitæ bushing forced into the aperture furnished in the aluminium trolley holder. About the bushing an oil well is provided to keep up perfect lubrication. With an insulating bearing of this sort some special contact arrangement is evidently necessary to lead the current from the wheel to the holder, and this is furnished by a pair of washers, one resting on the axle against the wheel, the other pressed against it by a flat spring, which leads the current to the holder. This particular form of trolley wheel is due to a Mr. C. Lieb of New York.

**Test of a 500 Horse-power Electric Lighting Engine.**—The following results of a recent test of a 500 horse-power triple expansion engine now in service at the station of the Narragansett Electric Lighting Company at Providence, R.I., may be of interest. The engine was built by the E. P. Allis Company, of Milwaukee, Wis., and was operating arc lights. The test was conducted by Messrs. E. D. Leavitt and John T. Henthorn. The engine is of the Reynolds-Corliss condensing type, and its three cylinders are of 14, 25 and 33 inches diameter respectively, the length of the stroke being 48 inches. At the time of the test the street lights were burned to determine the load which came nearest to 500 indicated

Digitized by Google

horse-power. With 500 lights the aggregate load was 492 indicated horse-power, or 475·7 indicated horse-power, omitting the auxiliary engine working the condensers. From this it appears that ·984 indicated horse-power was required for each arc light. The test lasted 10 hours. The average speed was 99·12 revolutions, average steam pressure, 125·2lb., average aggregate indicated horse-power, 532·11; steam used per indicated horse-power per hour, 12·94lb.

**Fireproof Insulation.**—A patent has recently been taken out by Mr. Edison, says the *India Rubber Journal*, for a method of applying fireproof insulating covering to wires for electrical purposes. The material used as a basis for the compound is either balata or gutta percha; the gum is first dissolved in chloroform, and a stream of chlorine gas passed through the solution. This process eliminates the hydrogen from the material, and leaves a compound which is fireproof, and, if the chlorination is stopped at the proper time, pliable. During the passage of the chlorine, tests are made from time to time by depositing films of the composition on glass plates and igniting them; when the film refuses to ignite the proper stage has been reached and the supply of chlorine is cut off. The compound is then ready to be applied to the wire in the usual manner, by being reduced to a plastic condition and forced through a die. The process, says our contemporary, sounds more like a laboratory experiment than a practical method, and is likely to be both costly and dangerous, dangerous as regards the health of the *employés* employed. It is also questionable whether the resulting material would possess the very necessary quality of durability.

**London County Council.**—At the last meeting of the London County Council, Mr. Beresford Hope asked the chairman of the offices committee whether, in the case of the failure of the electric light, the Council had any remedy against the lighting company, as was the case when the supply of gas failed. Mr. Brereton, the chairman of the offices committee, replied that he should like to have notice of the question. He had received a letter from the London Electric Supply Company expressing their regret that their temporary measures to restore the supply of electricity had not proved effectual, and that they were consequently compelled to suspend the supply until the permanent apparatus could be replaced. The work was proceeding with all possible speed, although it might be some weeks before a full supply could be given.—Mr. Fardell, chairman of the theatres committee, stated that, at the last meeting of the Council, the theatres committee were empowered to engage the services of an electrician of eminence to report upon the danger, if any, of the various systems of electric lighting in theatres and large buildings. The committee had been in communication with Prof. John Hopkinson, and had engaged his services subject to the consent of the Council.

**The Chelsea Electricity Supply Company and its Customers.**—In the House of Commons on Monday last, Mr. R. Chamberlain asked the President of the Board of Trade whether his attention had been called to the long-continued default of the Chelsea Electricity Supply Company to furnish current at the statutory pressure of 100 volts, and to the serious loss of illuminating power sustained by consumers in consequence; and whether he would take steps to compel this company to keep faith with the public or to forfeit their concession. In reply, Sir M. Hicks-Beach said that if the Board of Trade Regulations with regard to the maintenance of a constant pressure were not complied with it was open to the consumer to proceed against the company for penalties. Mr. Chamberlain further asked whether the attention of the President of the Board of Trade had been called to the fact that the variation allowed by the Board of Trade was taken advantage of in order to supply the consumers not with an average of 100 volts, but of 97. Sir M. Hicks-Beach, in reply, said that if the company was in default the consumers had their remedy. It was not for the Board of Trade to enforce the law. Mr. R. Chamberlain then asked if he was to understand that he had no remedy unless they got below 96 volts. Sir M. Hicks-Beach replied in the affirmative.

**The De Morgan Medal.**—The following extract from an address to the London Mathematical Society by its President, on the recent occasion of the presentation of the De Morgan Medal to Lord Rayleigh, may be of interest:—"In 1869 Lord Rayleigh commenced the long series of papers and memoirs in mixed mathematics, which the Council had in view in making the award, with an article (*Philosophical Magazine*, Vol. XXXVIII., Third Series) 'On some Electro-magnetic Phenomena considered in connection with the Dynamical Theory,' founded on Clerk-Maxwell's celebrated 'Dynamical Theory of the Electro-magnetic Field' (*Phil. Trans.*, 1865), the subject being 'Examples of Electro-magnetic Problems illustrated by comparison with their Mechanical Analogues.' I may add, to complete the key-note thus struck, of Lord Rayleigh's scientific career, that these theoretical results were followed up in the next year by an account of 'An Electro-magnetic Experiment,' viz.: the magnetising effect of an induced current as dependent on the self and mutual inductions of the circuits—an early instance of the author's practice of making theory and experiment, or concrete example, illustrate one another. This combination of experimental with mathematical skill and fertility of resource has been conspicuous in Lord Rayleigh's later memoirs on the 'Determination of the Ohm and B.A. Unit of Resistance in Absolute Measure.'"

**Coral Growths on Submarine Cables.**—Submarine cables have before now rendered unexpected services to science, and the following is one of the latest:—Very little, it seems, is as yet known as to the rate of growth of corals, but some very interesting details have been published by M. Alexander Agassiz in the August number of the *Bulletin of the Museum of Comparative Zoology at Harvard College* with regard to a series of specimens which were taken in June, 1888, off the Havana and Key West cable, from a portion repaired in the summer of 1881; so that the growths could not be more than about seven years. It must be noted that this portion of the cable was laid at a depth of only from six to seven fathoms, and that the district in which it was laid was most favourably situated as regards food supply to the corals. Some of the specimens belong to species whose rates of growth have not yet been recorded. Verrill mentions that the thickness of the *Orbicella annularis* coral formed in 64 years was not more than about 8in.; the specimens from the Havana cable grew to a thickness of 2½in. in about seven years. *Manicina areolata* has grown to a thickness of 1in.; while *Isophylla dipsacea* shows a still more rapid growth, projecting 2½in. above the cable. Of course it is quite possible that these corals are of less than seven years' growth, but it is not probable that more than a short time passed before some of the swarms of pelagic coral embryos which must have floated past the cable found a place of attachment thereon.

**Obituary.**—We regret to record the decease of Hermann Gustav Erichsen, which took place in London on the 6th inst. He was born at Copenhagen on October 6, 1828, his father being a well-known Danish merchant. After having received a thorough commercial education at Copenhagen, which was completed by visits to several of the more important places on the Continent, he came to Newcastle-on-Tyne in 1848. Some few years after he established the firm of Hunter and Erichsen, which in a very short time he worked up to a position of good standing. Towards the end of the sixties Mr. Erichsen came into connection with the leading telegraph men in England, and took a large share in the formation of the Great Northern Telegraph Company, whose representative in England he remained up to the time of his death. He also participated to a great extent in the formation of other undertakings, especially in Denmark, and always took a great interest in everything relating to his native country. He was decorated by the Danish Government with the Order of Knight of Danebrog, as well as with the silver cross of the same Order, and held besides other foreign Orders. He was Chairman of the China and Japan Telephone Company, as well as a Director of the Tramways Union Company, the Central Borneo Company, and the Telephone Company of Ireland. The funeral service took place on the 10th inst., at the Tooting Graveney Parish Church, and was attended by the family, the Danish Consul, Mr. F. C. C. Nielsen, and nearly all the staff of the London office of the Great Northern Telegraph Company, Mr. W. R. Lyne, representing the Eastern Extension Telegraph Company, and some 50 other gentlemen.

## MAGNETISM IN IRON AND OTHER METALS.*—XXXVII.

BY PROF. J. A. EWING, F.R.S.

(*Continued from page 100.*)

§ 134. **Experiments showing Residual Effects of Stress.**—In the following case an iron wire† (previously hardened by permanent strain) was loaded with a weight of 18·5 kilos., or 42·5 kilos. per sq. mm. This weight was repeatedly applied and removed, then finally removed; the wire was demagnetised by reversals, and the magnetising process was then gone through, giving the magnetometer readings stated in column I. of Table XXIII. Then the wire was demagnetised: the weight of 18·5 kilos. was applied and removed, and then the process of magnetising was again gone through, giving the magnetometer readings in column II. Finally, the same thing was repeated, but with this difference, that the wire was briskly tapped after the load had been removed before beginning to magnetise; the results of this are given in column III.

TABLE XXIII.—*Magnetisation of Iron under the influence of previous loads.*

| H | Magnetometer readings. | | |
|---|---|---|---|
| | I. After demagnetisation with no load. | II. After the cycle 0 – 18½ – 0. | III. After the cycle 0 – 18½ – 0 and then vibration. |
| 0 | 0 | 0 | 0 |
| 1·15 | 5 | 8 | 5 |
| 2·01 | 11 | 19 | 10 |
| 2·87 | 19 | 40 | 17 |
| 4·31 | 44 | 73 | 35 |
| 5·75 | 78·5 | 110 | 70 |
| 8·62 | 149 | 176 | 150 |
| 11·50 | 212·5 | 230 | 214 |
| 14·37 | 267 | 278 | 268 |
| 17·25 | 314·5 | 321 | 314 |
| 20·12 | 355 | 358·5 | 354 |
| 23·00 | 390 | 394 | 388 |
| 25·87 | 420 | 420 | 422 |
| 33·12 | 472 | 472 | 471 |

Comparing the three columns, it will be clear that in the first and third case the metal is in substantially the same condition as to susceptibility. In the third case its susceptibility with respect to low magnetic forces, and even to moderately great forces has been raised, as a consequence of the molecular change brought about through application and removal of the load. The same change had occurred in the other two cases, but it had been undone by the demagnetising force in one, by vibration in the other.

Experiments of this kind lead to the conclusion that when we apply and remove stress in iron, even when the magnetic state is perfectly neutral, we cause some kind of molecular displacement in the relation of which to this applied stress there is hysteresis. When any load is applied and removed the change of molecular configuration lags behind the changes of stress. We accordingly find, if we stop at any intermediate value of the load and examine the susceptibility, that the result is not the same when the stoppage is made during the process of loading, as when it is made, at the same amount of load, during the process of unloading. Magnetic susceptibility may, of course, be thought of as a physical property of the metal, apart from the existence of any actual magnetisation. During the loading and unloading of an unmagnetised piece the susceptibility changes in a manner that involves hysteresis, just as the magnetism changes when we load and unload a magnetised piece.

In Table XXIV. four magnetisations of the same iron wire are exhibited, each pulling under a load of 3 kilos.‡ In I., the load had been previously raised to 18½ kilos., then reduced to 3 kilos. In II., the load had been directly raised to 3 kilos., after demagnetising under no load. In III. and IV. these conditions were repeated, but the wire was subjected to vibration before the magnetising process began. It will be seen that between I. and II. there is a marked difference, especially in the early portion of the curve; but in III. and IV. this difference has disappeared, the effects of hysteresis being destroyed by vibration.

TABLE XXIV.—*Magnetisation of Iron under the influence of previous loads.*

| Galvanometer readings. (To reduce to H multiply by 0·0575.) | Magnetometer readings. | | | |
|---|---|---|---|---|
| | I. Demagnetised with no load. Then 0 – 18½ – 3. Load = 3 kilos. | II. Demagnetised with no load. Then 0 – 18½ – 0 – 3. Load = 3 kilos. | III. Demagnetised with no load. Loaded to 18½, unloaded to 3 kilos., and *tapped* before magnetising. Load = 3 kilos. | IV. Demagnetised with no load. Loaded to 3 kilos. and *tapped* before magnetising. Load = 3 kilos. |
| 0 | 0 | 0 | 0 | 0 |
| 25 | 22 | 13 | 11 | 10 |
| 50 | 70 | 14 | 36 | 34 |
| 75 | 139 | 109 | 103 | 100 |
| 100 | 198 | 176 | 174 | 168 |
| 125 | 242 | 226 | 227 | 219 |
| 150 | 276 | 265 | 268 | 259 |
| 200 | 328 | 323 | 328 | 320 |
| 250 | ... | 365 | 369 | 365 |
| 300 | 398 | 398 | 403 | 400 |
| 350 | 424 | 425 | 429 | 427 |
| 450 | 461 | 462 | 467 | 466 |
| 588 | 491 | 494 | 499 | 498 |
| 0 | 274 | 275 | 277 | 276 |

Again, Fig. 113 shows two pairs of curves, two (I. and II.) taken under no load, and two (III. and IV.) taken under a load

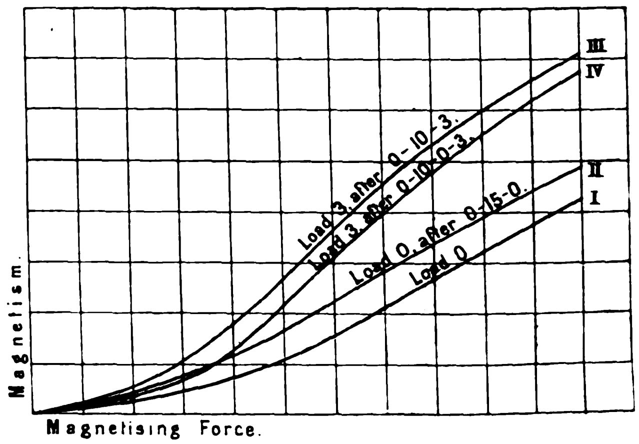

FIG. 113.—Residual Effects of Previous Loads.

of 3 kilos. In I., the wire was demagnetised immediately before the curve was taken. In II. it was demagnetised, then loaded with 15 kilos., and then completely unloaded. In III. it was loaded with 10 kilos., and unloaded down to 3 kilos. In IV. it was completely unloaded from 10 kilos., then reloaded up to 3 kilos. Very similar effects have been observed when annealed iron (not previously hardened by stretching) is tested under corresponding varieties of condition in regard to previous stress.*

The changes in molecular structure which, as these results show, are going on in iron or steel during the process of applying and removing stress sometimes result in producing a small amount of magnetism in a piece which, after being magnetised, has been brought into an apparently non-magnetic state by the application of a reversed force. There are, in such a case, superposed magnetisations which originally neutralise each other so far as external effect is concerned, but the balance is disturbed through the unequal action of the stress upon them.

* All rights are reserved.

§ 135. **Other Evidences of Hysteresis in the Effects of Stress.**—These experiments show that the structure of iron changes, under variation of stress, in a manner that exhibits hysteresis, that is to say, the changes of structure lag behind the changes of stress. We may therefore anticipate that we shall find traces of hysteresis in other physical qualities besides magnetic susceptibility when we examine the variation of these qualities under variations of stress.

A remarkable instance is furnished by the thermo-electric quality of iron. Under variations of pull the thermo-electric quality of iron varies in a manner which strikingly resembles those variations of magnetic quality which have been described in this chapter. This is not a secondary effect, resulting from changes of magnetism, for it occurs even when care is taken to keep the iron wholly free from magnetisation during the experiment. Curves drawn to represent the relation of thermo electric quality to load show a very remarkable general resemblance to the curves of Figs. 108-110, which show the relation of magnetism to load. There are also interesting points of difference, but a discussion of these would be out of place here. The main point, which was discovered by E. Cohn*, and afterwards, independently, by the writer†, is that there is much hysteresis of thermo-electric quality with respect to stress—a result, no doubt, of the irreversible changes of molecular structure to which allusion has already been made. We shall see later, in connection with molecular theories of magnetism, how these irreversible changes probably occur.

Further, but slighter, evidence of the occurrence of irreversible molecular changes during the loading and unloading of an iron wire is found when we examine the amount of the extension in relation to the load. Though the amount of load be restricted so that it lies well within the so-called limit of elasticity, it is found that there is no exact proportionality of strain to stress; and when a cyclic process of loading is repeated often enough to make the elongation and retraction become also cyclic, it is found that, at any intermediate value of the load, the wire is longer during unloading than during loading. In other words, there is hysteresis in the relation of strain to stress. The amount of this hysteresis is small; but when means are taken to magnify the extension sufficiently it may be observed without difficulty. The amount of difference in length between the length at the mean load in loading and the length at the mean load in unloading, may be $\frac{1}{300}$ of the change of the whole extension. The effect in question has to be distinguished from quasi-plastic changes of length, which depend on the time-rate at which the loads are applied. It has been observed in wires of copper and brass, as well as iron and steel.‡ One obvious consequence of it is that any process of loading and unloading involves some dissipation of energy.

*(To be continued.)*

## DRUM ARMATURE WINDING.

BY F. M. WEYMOUTH.

*(Continued from page 137.)*

We may now proceed to the consideration of another type of drum-armature winding, which, especially as regards the end connections, differs entirely from any of the foregoing. This is the arrangement of Mr. Gisbert Kapp. Here the cross connections, instead of being laid as convolutes or discs, are arranged helically, in fact like the threads of a many threaded screw. In the case of copper plate connectors, a common carpenter's wood screw, with thin, flat, and deep threads, will convey perhaps the best approximate idea. Fig. 35 represents a part longitudinal section through an armature thus wound. The thickly placed vertical lines, O O, are sections through the series of helical connectors. These will be better understood, however, from the developed plan shown, Fig. 36. The inner ends of the connectors, it will be observed, are jointed to the short parallel bars, as at *a a*, while the outer ends are jointed to the long

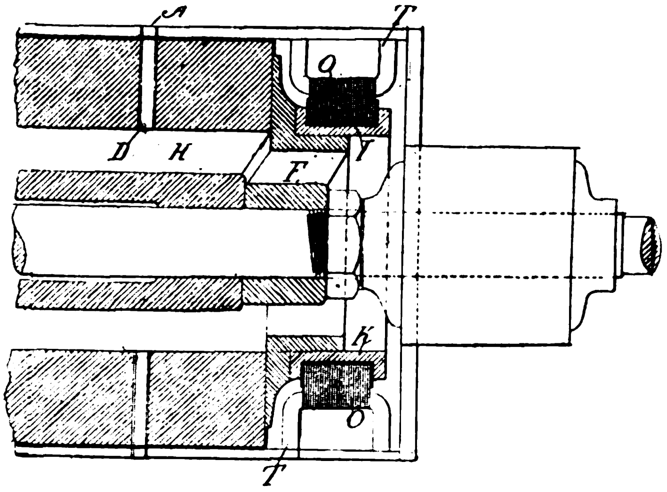

FIG. 35.—Kapp Winding. Longitudinal Section through Armature.

parallel bars at *b b*, the unions being effected by means of tags T T, Fig. 37, formed on the ends of the connectors for the purpose. A single helical connector is shown, Fig. 37. B B are the parallel conductors forming two sides of a coil,

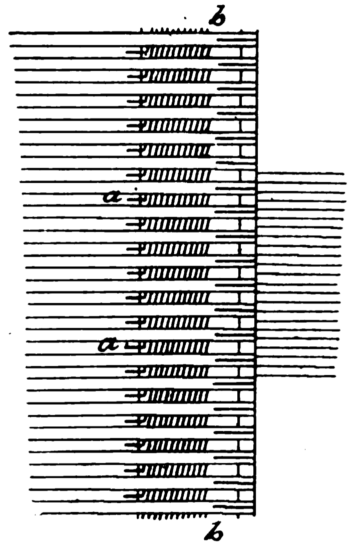

FIG. 36.—Kapp Winding. Plan of Helical End Connections.

T T the tags, and *s* the commutator lug. The dotted lines S S′ show a true segment of a circle, thus making clearer by comparison the helical or spiral form of the connector. Solid bar or wire connectors in the forms of insulated copper wire cable,

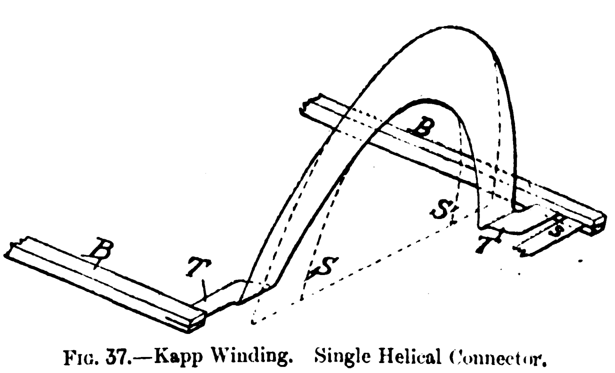

FIG. 37.—Kapp Winding. Single Helical Connector.

may also be used as shown in Fig. 38. A layer thus formed of bar or cable being of little radial thickness, other layers may be superimposed. As, however, the connectors in the outer layers must necessarily be longer than those in the inner layers,

* Cohn: Wied. *Annalen*, 1879, p. 385.

† *Proc. Roy. Soc.*, May 1881; see also a later and fuller paper in *Phil. Trans.*, 1886, p. 361 (Effect of Stress and Magnetisation on the Thermo-electric Quality of Iron), where curves are shown illustrating the hysteresis in thermo-electric quality referred to in the text.

‡ See a Paper "On Hysteresis in the Relation of Strain to Stress." Rep. Brit. Assoc., 1889, p. 502.

Digitized by Google

this latter method would appear not to have the symmetry of the helical plate arrangement.

Returning to the plate connectors, each helix, it will be observed, goes round approximately half a circle (for a two-pole machine). All the helices, insulated from each other, are laid together in an annular frame I (Fig. 35) of wood, or other insulating material, and are held there by taping or otherwise; this frame is in turn held in a metal sleeve K, which is mounted on a shoulder of the end-plate F. Thus this end-winding has the peculiarity of being quite self-contained, and so can be made up separately, and not put on the armature till complete in itself. It will be observed that as the helices are attached at their ends to *alternate* parallel bars, between which there can only be a minimum pressure, there will likewise be only a minimum pressure between adjacent helices. Only a slight amount of insulation is consequently needed between them.

An obvious advantage of this system over the convolute may be observed. If a large number of connectors are

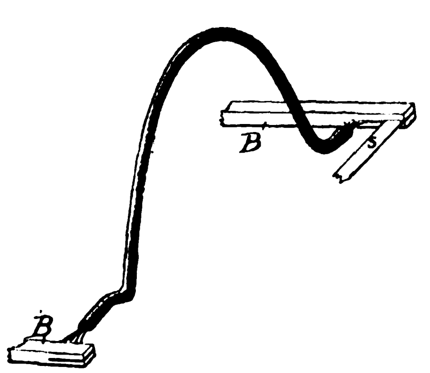

Fig. 38.—Kapp Winding. Single Helical Connector of Copper Wire Cable.

needed, it is not necessary to have two series, but merely to widen the one series in a direction parallel with the shaft. The "pitch" being thus increased, a greater number of any given thickness can be got in. As to ease of construction and replacement, it will be observed that all the joints are on the outside and accessible. In the core, at intervals, are placed metal discs with projecting horns A for driving the winding, and air spaces D at either side of these discs allow for ventilation. The core has a large central bore, admitting plenty of air, and is carried on a spider H as shown. It will be observed that, as with the Edison discs, these plate connectors require to

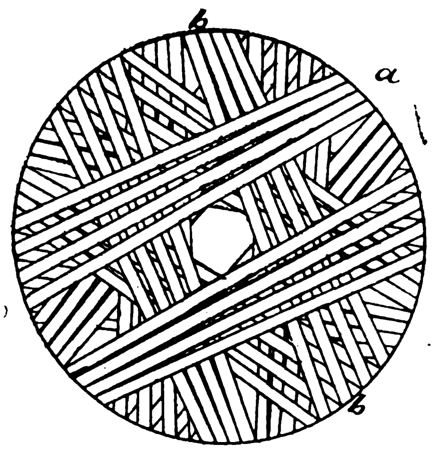

Fig. 39.—Swinburne's Chord Winding.

be stamped out of sheet: hence the same remarks as to waste of material and cost of labour, &c., will apply, the question remaining as to whether or not this is made up for by subsequent economy in labour of construction. This end-winding is very compact and symmetrical, with comparatively few joints, and these easily accessible, beside having the other advantages already mentioned, including free access for ventilation.

The next winding we come to is another of Mr. James Swinburne's. In this case the peculiarity exists that the coils, instead of being wound over diameters, are wound over chords of the circumference of the armature. An application of this principle to a wire-wound armature is shown in Fig. 39. It will here be seen that the end wrappings, lying in chords as at *a a* or *b b*, keep clear of the centre, and thus, especially when the chords subtend smaller angles at the centre than here represented, allow room for ventilation through the hollow of the core. For large low-pressure currents the method of coupling up across the ends is as shown, Figs. 40 to 43. Curved

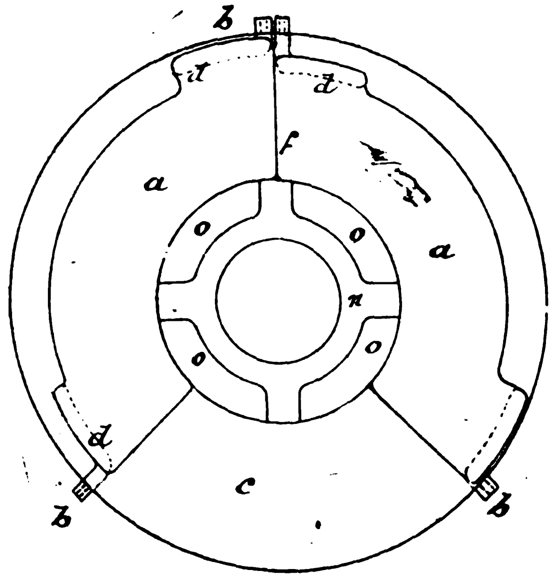

Fig. 40.—Swinburne's Chord Winding. End View of Armature, Two Connectors *in situ*.

stamped copper plates *a a* form the connectors. These are laid two in a plane normal to the axis of the armature, and with their edges butting as at *f* (Fig. 40). Connecting pieces *d d* are attached to the plates by means of which union with the bars *b b* is formed. The plates covering more than a third of a circle each, the space *c* may be kept clear for ventilation. Otherwise the plates may be laid slightly helically, and overlap one another. A spider *n* carries the core, passages *o o* being left for ventilation. Figs. 42 and 43 show separate views of one plate connector, with the addition of a tag *g* formed on the interior edge for interior union with the commutator, if such should be desired.

Foucault currents are dealt with by making each conductor bar of parallel strips or bars, and then connecting these up separately across the pulley end, as shown in Fig. 8 (*The Electrician*, November 21st, p. 72), it being borne in mind that

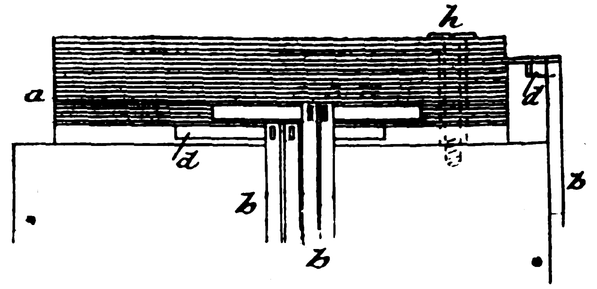

Fig. 41.—Swinburne's Chord Winding. Method of Connecting the Connector-plates to the End Plates of Armature Core by Insulating Screws *h*.

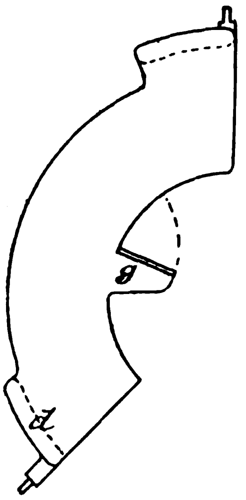
in the case before us these connectors will be taken across a chord and not a diameter.

It would appear that in this end winding, as with Edison's discs, the close proximity of connector plates of maximum and minimum volts is not avoided. It will be observed, further, that the sum of the areas enclosed by the coils is not so great as would be the case were the winding diametrical. The plates require to be stamped; while, on the other hand, the construction is simple, and all the joints are outside and accessible.

Digitized by Google

The connector plates are held in a mass to the end plates of the core by means of insulated screws, one of which is shown at *h*, Fig. 41. These screws of course also act as drivers, obviating the necessity of any special means for that purpose. Ventilation, as already intimated, is well provided for.

There are, however, some further points in connection with this winding which it may be of interest to consider. For the



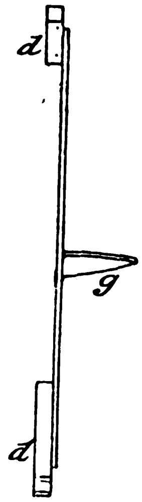


Fig. 42. Swinburne's Chord Winding. Fig. 43. Separate Views of a Connector.

better elucidation of these, a diagramatic representation of this system is appended in Fig. 44 A. The pulley end is here shown. The outer radial lines *y y* represent the commutator lugs at the further end extended on magnified diameters

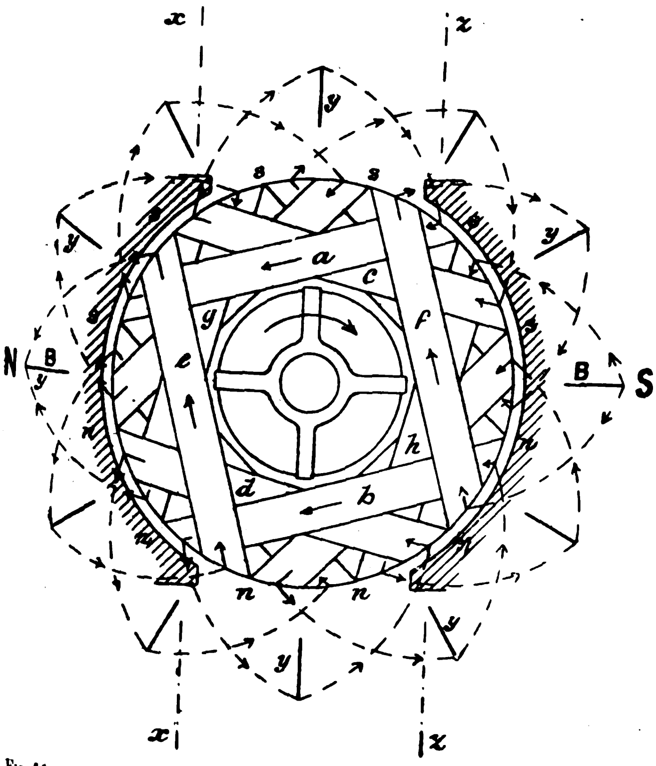

Fig. 44A.—Swinburne's Chord Winding. Diagrammatic Sketch of System.

to make them visible. The curved dotted lines indicate the connections thereto. The lugs lettered B B are those of the segments on which the brushes rest, the left-hand one being the positive brush of the machine and the right-hand the negative, while the union with the commutator is supposed to be from the middle of a connector. Inspection will make it clear that the current flow is as shown by the small arrows. The pole pieces are also indicated, **N** and **S**. The small letters *n* and *s* around outside the circumference of the armature show the polarity which each pair of parallel coils tend to produce. Thus the coils *a* and *b*, *c* and *d*, tend to produce between them a vertical polarity, each reinforcing the other, with a south pole above, and a north pole below. The pairs *e f* and *g h* tend to produce each an approximately horizontal polarity parallel with the field, but contrary to each other. These latter thus neutralise each other, with the result that the vertical polarity alone remains. In relation to the armature itself, this may be called its *primary* polarity. In relation to the field this is

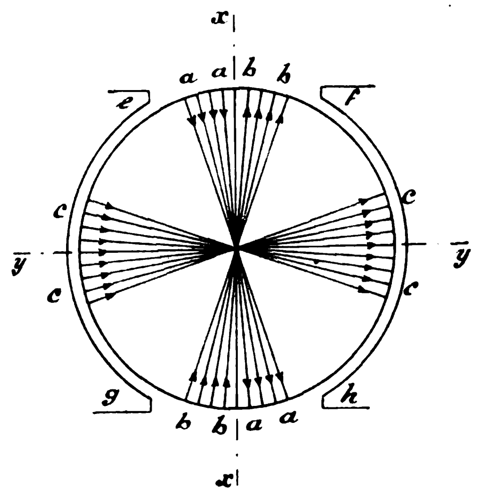

Fig. 44B.—Ordinary Diametrical Drum-winding. Diagram of Current Flow.

known as cross-magnetisation, or cross-induction, as it is at right angles to the field. Now it will be observed that on the upper and lower sides of the armature, as sketched in Fig. 44 A, the current is running in opposite directions in adjacent parallel conductors, while at the sides next the pole-pieces the current runs the same way in all on one side. It is claimed in Mr. Swinburne's patent, that by virtue of this arrangement of current direction, the cross-magnetisation is reduced.

In ordinary diametrical drum-winding, of the coils approximately parallel to the plane of commutation on either side of it, those on the one side neutralise the polarising effect of those on the other side. Thus in Fig. 44 B, where *x x* is the plane of commutation, the coils *a a* neutralise the effect of the coils

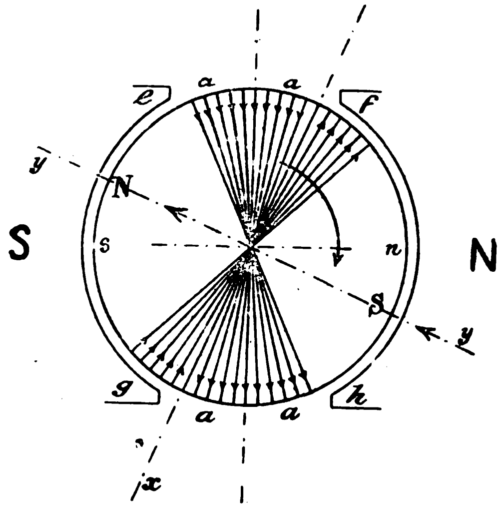

Fig. 44c.—Same as Fig. 44B. Brushes Shifted.

*b b*, in which the current is running in an opposite direction, as shown by small arrow-heads. On the other hand, the polarising effect of the horizontal coils *c c* is unopposed, and produces the vertical primary polarity of the armature coincident with the plane of commutation *x x*, which in relation to the field, as we have already mentioned, is known as cross-magnetisation.

Let us now suppose the brushes to require a lead. The plane of commutation becomes tilted as shown *x x* Fig. 44 c. Now note the effect. The coils *a a a a* are brought normal to

Digitized by Google

the field. Hence these will produce a polarity *parallel* to the field. In generating dynamos a north pole in the armature becomes opposed to the north pole-piece, and a south to the south, as indicated by small letters *n* and *s*, in direct opposition to the field. We thus find this polarity parallel with the field, termed, in the case of generators, the "back induction"; and its effect is to weaken the field. In the case of motors, wherein we may imagine the **N** and **S** pole-pieces to exchange places, the reverse holds good, and this parallel induction reinforces the field. Thus the further phenomenon arises, in the case of motors, that with an armature revolving between *non-magnetised* pole-pieces, and having a tilted plane of commutation, the south pole of this parallel induction will *induce* a north pole in the pole-piece opposed to it, and a south pole will similarly be *induced* in the other pole-piece. Thus, with induced pole-pieces only, a motor can be run in a primarily non-magnetised field, though it may not pay to do so in practice. It will thus be observed, that while a tilted plane of commutation is not on this account detrimental to a motor, but rather the contrary, it is detrimental in the case of a generating dynamo. Hence, to avoid this evil in the latter case, with its attendant consequences, the field is made so strong as to draw the primary cross polarity of the armature as nearly as possible parallel to itself. The ultimate effect is in any case a compromise between the armature polarity and the field; and in proportion as the disparity is lessened, so great is the "distortion of the field." Thus, in Fig. 44 c, the lines of force of the field, instead of running straight across through the armature from **N** to **S**, will pass through along *y y* as a centre line of their course, the angle between *y y* and the horizontal being the measure of their distortion. The peculiarity will thus be noted that the primary polarity of the armature, or cross-magnetisation, is just exactly drawn down into the line *y y*, along which there is *no* primary polarity, as already pointed out, owing to the neutralisation of the coils *a a* and *b b*. The cross-induction thus diverted does not oppose the field. Assuming the plane of commutation to have been originally vertical, but the field becoming distorted by the armature, the brushes will require to be moved over till the plane of commutation is brought perpendicular to the new direction of the field, guidance as to when the correct position has been found being obtained by the absence of sparking at the commutator.

It may be further observed, referring to Fig. 44 B and C, that the whole of the armature above the line *y y* being north, and below, south, the horns *g* and *f* are opposed, and *e* and *h* reinforced, by the armature primary polarity. It thus comes about, that whether the plane of commutation be tilted or not, the lines of force gather thick at the horns *e* and *h*, which are the "trailing" horns, while at the other horns they become comparatively sparse. The Roman letters N and S indicate the ultimate polarity of the armature. In the case of a distorted field, Fig. 44 C, the main body of the lines of force running from the lower half of the **N** pole-piece and through the upper half of the **S** pole-piece, and these two halves thereby carrying the most lines of force, this further increases the accumulation at the horns *e* and *h*. The lines being drawn away from the horns *g* and *f*, these may become magnetised the wrong way if care be not taken.

Returning now to Mr. Swinburne's chord winding, and the claim for reduction of cross-magnetisation referred to, we find it difficult to see how this is made good. Referring to Fig. 44 A, we have found the cross-magnetisation to be due to the coils *a b c d*. The mixed bars above and below have but little effect in this direction, owing to the obliquity of the coils to which they belong. The whole of the upper half of the armature is of one pole, without primary opposition, and the lower half the other pole. The coils being on chords instead of diameters, it may be convenient to speak of two planes of commutation here, as represented by *x x* and *z z*. While these planes are vertical back induction cannot arise, as pointed out. But neither does it in diametrical winding. If the planes are tilted by a lead given the brushes, then back induction immediately sets up, as, for instance, the coils *e* and *f* becoming vertical will exercise influence opposing the field. In fact, with a lead to the brushes, a preponderance of the north primary polarity of the armature will be thrown against the north pole-piece, and of the south against the south pole-piece, and all the attendant consequences will follow as in the case of the diametrical winding. Hence it is not clear how this claim is substantiated; and this failing, it follows that this chord system of winding will not compare favourably with the diametrical winding, owing to the much smaller total area enclosed by the coils; unless, indeed, there be occult reasons in its favour, which have eluded investigation.

*(To be continued.)*

## THE CAPACITY OF SUBMARINE CABLES.

BY HAROLD W. ANSELL AND JULIAN E. YOUNG.

In *The Electrician* of September 5th Dr. Muirhead published a correction for the error in the determination of electrostatic capacities, arising from unequal rates of absorption in different dielectrics. The necessity of this correction, when the time of charge exceeds a few seconds, has long been apparent; and, as the figures in the paper alluded to show, it appears to achieve its object satisfactorily. Unfortunately, there are other sources of error in such measurements which have scarcely received the attention they demand. In the case of a cable, the leakage and retardation of the charge must be taken into account, as well as the rate of absorption, before the true capacity can be arrived at.

The following table is given with a view to showing the magnitude of the error introduced by moderate leakage *alone*, the condensers compared having similar dielectrics, and therefore absorbing at the same rate. The correction applied to the result obtained by balancing the potentials of the charges according to the usual method is as follows:—

$$\text{true capacity} = \frac{\text{apparent capacity}}{k},$$

$$\text{where} \quad \log k = \frac{t}{2{\cdot}3026\,F\,R},$$

$t$ being the time of charge in seconds, F the approximate capacity to be measured in microfarads, R the resistance of the leak in megohms. This expression, based on the laws of fall of charge, has been found sufficiently correct for practical purposes, taking R, in the case of a cable, as the dielectric resistance at the fifth minute.

| Time of charge. | Leak.' | Standard condenser. | Slide reading. | Log K. | Apparent capacity. | Corrected capacity. | True capacity. |
|---|---|---|---|---|---|---|---|
| Seconds. | Megohms. | Mfs. | | | Mfs. | Mfs. | Mfs. |
| 2 | 1 | 19·2994 | 8074 | 0·011136 | 80·904 | 78·856 | 77·987 |
| 5 | 1 | " | 8127 | 0·027839 | 83 741 | 78·541 | " |
| 15 | 1 | " | 8312 | 0·083518 | 95·033 | 78·407 | " |
| 5 | 3 121 | " | 8060 | 0·008920 | 80·182 | 78·552 | " |
| 15 | 3·121 | " | 8120 | 0·026760 | 83·357 | 78 376 | " |
| 5 | 0·500 | 19·860 | 6120 | 0·217140 | 31·325 | 19 000 | 19·500 |

If the time of charge does not exceed two or three seconds, the correction for unequal rates of absorption (as Dr. Muirhead's tables prove) is so small that it may be neglected. It is questionable whether the time need ever be made to exceed three seconds, since this is all that would be required to overcome the retardation of long cables, that is, to establish a practically uniform potential throughout the entire length of the conductor. This having been done, the cable may be regarded as charged, assuming the capacity as being that for receiving electricity from the first contact, and as distinct from "electrification." On page 331 of Jenkin's "Electricity and Magnetism," fifth edition, a formula is given by which the time for any length of cable can be calculated.

Some uncertainty generally exists as to the real capacity of cables, more especially of long ones. Discrepancies are often met with between the values specified by manufacturers, those obtained immediately after submersion, and those observed at subsequent times. Since the localisation of faults not unfrequently depends on these last, the desirability of a more

Digitized by Google

rigorous definition of capacity is evident. The following suggestions present themselves:—(1) That the true capacity of a cable should always be taken as the value of the instantaneous charge of one knot of its core, multiplied by the length of the line. (2) That, after submersion, the apparent value of the capacity should be taken to a fixed standard of time and method of observation, and corrected for the observed leakage by the formula given above, to reduce it to the value assigned by the foregoing definition.

With reference to the example given in the number of *The Electrician* already referred to, viz., the Porthcurno-Gibraltar cable, assuming that line to have a dielectric resistance of about five megohms at the fifth minute, which we understand is not far from the truth, the true capacity of that section would be about four microfarads less than 458·17. This value, which is quoted as standard, was presumably the sum of sections of considerable length, each involving leakage (not deduced from the knot-charge), and consequently too high. Both the standard and the corrected results cited would thus tend to coincide, although neither would represent *true* capacity.

## NOTE ON THE PROBABLE EXPLANATION OF A PECULIAR CLASS OF FAULTS OCCURRING IN SUBMARINE CABLES.

BY J. PARRY LAWS.

Some time ago I had my attention directed first by Mr. Saunders, of the Eastern Telegraph Company, and subsequently by Mr. Herbert Taylor, of Messrs. Clarke, Forde, and Taylor, to a particular class of faults occurring in submarine cables. The distribution of these faults is decidedly limited, occurring, as they do, only in water having a moderately high mean temperature, and in positions where it is not very deep. When the core is examined, it presents, strictly speaking, an appearance of simple decay, the gutta percha having undergone some chemical change, which renders it extremely brittle, and causes it to shrink in volume. I say chemical change advisedly, as there are no signs whatever of mechanical erosion; indeed, many of these faults are taken, I am informed, from parts of the cable where the outer covering of wire remained intact; the hemp, however, at the particular spot was entirely destroyed. These faults have therefore caused considerable speculation as to their origin, and the explanation I am about to suggest seems to me, on due consideration, to be at least feasible.

Taking into consideration the high temperature of the water, and the very limited position of these faults, I have come to the conclusion that they may probably be produced by the action of putrefying organic material either in actual contact with the cable or in close proximity to it. Guided by this hypothesis, I made some experiments on a laboratory scale to determine whether organisms, such as occur in putrefying fluids, or the products of their life, would have any effect on the core of submarine cables. The few experiments I have made show conclusively that putrefaction does exert a very marked effect upon gutta percha, some classes of putrefaction producing more effect than others. The few experiments I have been able to carry out are certainly confirmatory of the above suggestion, the gutta percha being considerably eroded and pitted after remaining in a putrid fluid for some time.

I hope to make experiments in greater detail, and publish the above as a mere suggestion, in the hope that others may collect facts tending to establish or disprove it.

## ON THE ILLUMINATION OF A HORIZONTAL PLANE.*

BY F. LOPPÉ.

The writer considers the problem of lighting a horizontal plane by means of a number of similar lights arranged so that the illumination at no place on the ground shall be less than a given quantity, E, and so that the energy expended in producing the light shall be as small as possible.

Two special cases are treated. In the first a large area is supposed to be illuminated by means of many lamps placed in rows, so that the poles stand at the corners of squares of equal size. In the second a street is supposed to be illuminated by means of lamps placed alternately on each side of the road, in the manner usual in practice.

It is assumed for simplicity that the energy required for producing the light is proportional to the amount of light produced. The problem may, therefore, be stated in the following way:—Given a certain amount of light, which, with certain limitations, may be distributed in any manner, how shall this light be apportioned so that the minimum illumination of the surface may be as great as possible?

The author first considers the illumination of a square (side $2a$), lighted by four lamps (height $h$) placed at the corners. It is shown that the light at the centre of the square is

a minimum if $h < a\sqrt{3}$

and a maximum if $h > a\sqrt{3}$

As in practice the first condition always holds, since lamps are placed farther apart from each other than from the ground, the illumination at the centre of the square is a minimum; and in the problem of lighting an area in the manner stated above, the quantity E refers to the centres of the squares.

In working out the condition that the total light used to produce the minimum illumination E may be as small as possible, it is shown that $L/4a^2$ must be a minimum where L is the candle-power of each lamp, and where the relation expressed by the following equation:—

$$2a^2 = \left(\frac{4h}{E}\right)^{\frac{2}{3}} L^{\frac{2}{3}} - h^2$$

connects the three unknown quantities, $a$, $h$, and L, with the quantity E, which is supposed given. If we assume one of the former three quantities known, we can find the best relation between the other two. By assuming L, or the candle-power of the lamps used, to be known, the best value for $h$ is shown to be

$$h = 0{\cdot}87\sqrt{\frac{L}{E}}$$

where E is measured in terms of the illumination produced by a candle placed at unit distance from the surface lighted.

If, on the contrary, $h$ is assumed known, the best value for L is given by the equation

$$L = 1{\cdot}30\, E h^2.$$

The second case, that referring to street lighting, is then considered, and it is shown that if L is fixed, the best value of $h$ is

$$h = 0{\cdot}62\sqrt{\frac{L}{E}}$$

while if $h$ is known, the best value for L is

$$L = 0{\cdot}92\, E h^2.$$

* Abstract from *L'Electricien*, October 18, 1890.

## THE BUDAPEST ELECTRIC TRAMWAY SYSTEM.

From a pamphlet just issued by Messrs. Siemens and Halske, we gather the following particulars of their electric tramway on the open conduit system now in operation at Budapest.

The channel has a uniform breadth of 11·2in. The slot giving access to the conductors is placed in the groove of one of the running rails, so that there is no more metal exposed in the roadway than is the case with horse tramway lines. At intervals of 4ft. along the channel, iron chairs 7·2in. broad serve to support the running rail, and also to carry insulators, to which the conductors are attached. The bottom of the channel, which is formed of concrete, is at a depth of 22·8in. below the surface of the roadway, and the slot between the rails which form its roof is 1·3in. wide. The conductors, of which there are two (positive and negative), consist of angle iron, and are placed at the sides of the channel so as to be out of sight and out of reach. The cars carry a single motor, geared to one of the axles, and four groups of resistance frames for regulating the speed. The current is supplied at a pressure of 300 volts.

Three lines with an aggregate mileage of five and a-half miles are at present in operation on the above system. A fourth line is at present building, but on this an overhead conductor is to be used. At the central station there are at present three 100 horse-power compound engines, each driving a dynamo by means of rope belts. A speed of 9½ miles per hour is allowed, and at certain parts this may be increased to over 11, whilst at others it has to be reduced to 6 and to 3¾. The day's work ranges from 75 to 95 miles per day per car.

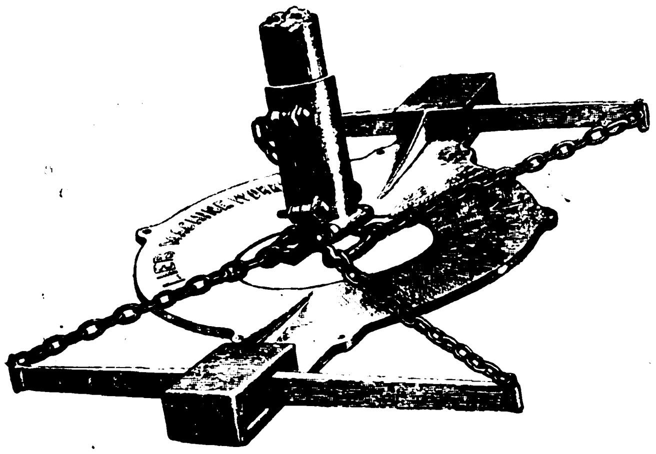
## THE LIEB TROLLEY BASE.

Since the electric railroad has come into general use (says the *Electrical World*) the ingenuity of inventors has been taxed to produce a trolley base having the combination of qualities most desirable for railway service. Flexibility in all directions without readjustment, combined with springs powerful enough to give the proper contact against the trolley wire, is, however, a hard condition to fulfil. A recent effort in this direction is that illustrated herewith. It is due to the ingenuity of Mr. Charles Lieb, of New York. The figure shows the general arrangement of springs. As will be seen, the spiral spring which has been almost universal in trolley work has been abandoned, and its place has been taken by two flat steel springs like carriage springs. These are supported on a single casting, which is bolted to the roof of the car. The socket for the trolley pole is provided at its lower end with a pair of wide links hinged upon each other; to each of these are attached two chains, one running to either spring. As a result, the socket is supported by four tense chains, and movement in any direction whatever tends to shorten these, and, consequently, gives the necessary upward pressure against the trolley arm. A special peculiarity of this form of spring is that when the pole is depressed below a certain point, the position of the links is such that it can be swung down parallel to the car roof with but little additional pressure, the maximum upward thrust being somewhere midway in the arc through which the pole can swing. This is a great convenience in passing under low bridges, and in laying up the car for the night, for this can be readily done without unshipping the pole.



Lieb Trolley Base.

The whole arrangement is singularly simple and strong, and possesses great flexibility in adapting itself to the various positions that must be taken by a trolley pole from time to time. It is usually fitted by Mr. Lieb with a wooden trolley pole supporting an aluminium trolley.

## THE PHYSICAL SOCIETY.

At the meeting of the Physical Society on Friday, November 28th, Prof. S. P. Thompson communicated a note, entitled,

### "An Illustration of Ewing's Theory of Induced Magnetism."

The author stated that he had never seen Prof. Ewing's model, illustrating the properties of a magnetic substance, and while casting about for the best means of building up such a model capable of being used for lantern demonstrations, he had found that small compass needles, already mounted in cases with glass at top and bottom, could be obtained at a very cheap rate in Clerkenwell. The model which he then exhibited to the Society simply consisted of a large number of these small compass needles, placed as close together as possible on a horizontal glass plate, through which the beam of light from a lantern was thrown. The only inconvenience attending the use of these ready-made compass needles was that owing to their shortness in comparison with the size of the cases in which they were mounted, their mutual influence was not strong enough to overcome the earth's magnetic field, which had, therefore, to be partly neutralised by means of a permanent magnet. This inconvenience, however, was more than counterbalanced by the facility with which the little needles could be arranged in various groupings, owing to their not all being attached to the same base.

The author proceeded to adjust the position of the permanent magnet until the needles showed no average set in any one direction. A magnetising coil with its axis east and west was then brought close to the model and excited by a gradually increasing current, when it was seen that successive groups of needles became unstable and assumed a definite set. The greater the distances between the needles, the more necessary it became to neutralise the earth's magnetic field; and the author thought that this might throw some light on the following phenomenon observed by him.

Magnetite or loadstone is found in two distinct forms, one consisting of a homogeneous mass of octohedral crystals, and the other being formed of heterogeneous crystalline masses. He had found that good natural magnets were always of the second kind, the regular form having little or no magnetic retentiveness. It would seem that in the former case the effective groups of particles were too far apart for their mutual forces to overcome even the weak magnetic field due to the earth.

#### DISCUSSION.

Mr. C. V. BOYS stated that a few weeks since, Prof. Rücker, who *had* seen Prof. Ewing's model, had devised an apparatus very similar to that just exhibited to the Society for the purpose of lantern demonstration; and Prof. Rücker, being unavoidably absent, had requested him to bring it before the Society. Prof. Rücker had not been aware that the small needles could be obtained already mounted, and they had therefore been prepared by cutting off a number of pieces of fine watch-spring, of equal lengths, and bending them by means of a tool into the form of the letter U. Small pieces of capillary glass tube, closed and rounded at one end, were fixed between the limbs of each of the magnets, which were then suspended upon a number of needle-points fixed with the points upwards into small leaden discs, which were cemented at a uniform distance apart, upon a circular glass plate, mounted in a wooden ring. The requisite magnetic field was produced by winding a few turns of wire across the ring in grooves cut for the purpose. This model showed very clearly that no instability is produced until the current reaches a certain strength, and that when the strength was reduced with sufficient slowness, the system remained magnetic.

Mr. SWINBURNE observed that Ewing's theory would lead to the conclusion that the magnetic susceptibility must be negative when the temperature of demagnetisation was attained, and he had written to Prof. Ewing on the point, and understood from him that he *had* observed some indications, that this might be the case. He did not see how Ewing's theory explained the great loss of energy in a rotating mass of iron such as the armature of a dynamo. He would like to see some experiments carried out to try whether any state of unstable equilibrium could be found in such a rotating mass.

Prof. AYRTON stated that some years ago he had heard from Prof. Lodge that he was trying to detect the existence of negative susceptibility. The sudden drop in the characteristic curve of a dynamo might possibly be due to this, if it existed.

Mr. H. TOMLINSON observed that it was easier to experiment in this direction with nickel than with iron, owing to its losing its magnetism at about 300°C. instead of at about 700°C. as in the case of iron. He stated that he had looked for negative susceptibility in nickel with exceedingly delicate apparatus; but though his experiments extended over a range of from 300°C. up to over 500°C., he had been unable to discover any trace of negative susceptibility.

Mr. T. H. BLAKESLEY also read a Paper on

### "The Solution of a Geometrical Problem in Magnetism."

The author proposed the following problem:—Given the two poles of a magnet, and a straight line intersecting at right angles its axis, produced at a given point, to determine at what point this line is parallel to the field. He pointed out that the solution was of some theoretical interest, because if the points were experimentally known, the distance between the virtual poles of the magnet could be determined; moreover, the question was of practical importance from its bearing upon the question of the deviation of a compass needle in certain cases.

Let A B (Fig. 1) be a long, uniformly magnetised rod, having poles at A and B. Say A is the north pole, and let O D be its equatorial plane. Then the field at P is always parallel to, and in the direction of, A B, which he calls the positive direction. Let the space C D be cut away, leaving a gap, having the same equator. Then a south pole will be formed at C, and a north pole at D; and these will produce at P a negative field parallel to D C. The resultant field will be negative or positive, according as P is near to O, or remote from it. There must, therefore, be a point at which the field will vanish, and at which, therefore, two rods, A C and D B, would produce no compass deviation, whatever the bearing of the ship carrying the system. Such a pair of permanent magnets would produce what is known as semi-circular deviation of a compass needle situated at any distance from O except the critical one, that is to say, through one semicircle the deviation would be easterly, and through the other westerly, but these would be inverted by passage through the critical point. If, however, the rods A C and D C were of soft iron, so as to be liable to magnetisation by the action of H, the horizontal component of the earth's magnetism, the general effect would be that the direction of the deviation would change sign after every quadrant, the devia-

Digitized by Google

tion being the same in opposite quadrants, the sign for any pair of opposite quadrants depending on the position of the compass relative to the critical position. The critical point is clearly one for which the field due to either magnet A C or D B alone would be entirely along O P. That is, at right angles to the axis of the magnet.

Let M and N (Fig. 2) be the positions of the poles of a magnet, and P, a point at a distance $d$ from O, O being in the axis of the magnet produced, and P O being at right angles to O M N. Let O M$=m$, and O N$=n$, and let $p$ be the numerical value of each of the poles M and N. Then the condition that the component

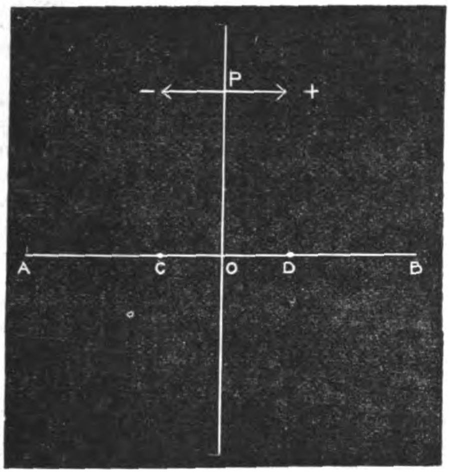


Fig. 1.

parallel to the magnet of the field produced at P by $p$ at M shall be equal and opposite to the same thing produced by $p$ at N is

$$\frac{m}{(d^2+m^2)^{\frac{3}{2}}} = \frac{n}{(d^2+n^2)^{\frac{3}{2}}} \quad . \quad . \quad . \quad . \quad . \quad . \quad (1)$$

from which $d$ can be determined.

This equation can be transformed into

$$\frac{d^3}{2mn} - \frac{3}{4} \cdot \frac{d^2}{2mn} - \frac{1}{4} \cdot \frac{m^2+n^2}{2mn} = 0 \quad . \quad . \quad . \quad . \quad (2)$$

The solution of this equation is facilitated by comparing it with the formula in hyperbolic trigonometry.

$$\cosh^3\theta - \frac{3}{4}\cosh\theta - \frac{1}{4}\cosh 3\theta = 0 \quad . \quad . \quad . \quad . \quad (3)$$

for if we make $$\frac{m^2+n^2}{2mn} = \cosh 3\theta \quad . \quad . \quad . \quad . \quad . \quad . \quad (4)$$

we have $$\frac{d^2}{2mn} = \cosh\theta \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (5)$$

So that $d$ can easily be found from the author's "Tables of Hyperbolic Sines and Cosines," recently published by the society.

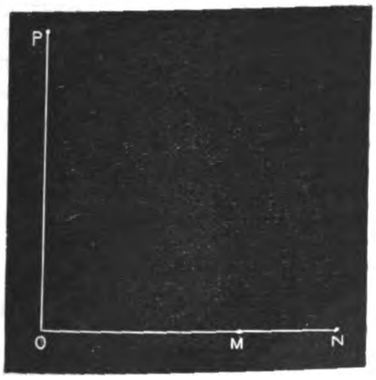

Fig. 2.

By applying the proposition inversely, the virtual distance between the poles may be determined.

To produce this state of things practically arrange a small magnetometer needle in the meridian, and find the direction of the axis of the needle by the condition that a long magnet laid in that line will not affect the position of the magnetometer needle. Then place that magnet or another one at right angles to this position, and move it in the direction of its length until the needle of the magnetometer returns to its former position. Then $d$ is known, and also $m+n$, because the distance of the middle point of the magnet perpendicularly from the axis of the magnetometer needle is $l=\frac{m+n}{2}$. The whole distance $m-n=2a$ may be obtained from equations 4 and 5, for

$$\frac{m-n}{m+n} = \frac{2a}{2l} = \frac{a}{l} = \tan h\,\frac{3\theta}{2},$$

where $$\frac{l}{d} = \sqrt{\frac{\cosh 3\theta+1}{4\cosh\theta}},$$

a function which can easily be determined by the aid of the tables.

Experiments of this kind showed that the virtual distance between the poles rapidly approached the full length of the magnet as the latter increased. The expression for the strength of the field under the circumstances is

$$\frac{4\,\text{M}}{d^3}\;\frac{\cosh^2\theta}{(4\cosh^2\theta-1)^{\frac{3}{2}}}$$

Where M is the moment $p\,(n-m)$.

This expression may be simplified by choosing $d$, so that $\cosh^2\theta = \frac{5}{4}$. Then the strength of the field is $\frac{5\,\text{M}}{8\,d^3}$; but

$$\cosh\theta = \frac{\sqrt{5}}{2}\;;\;\cosh 3\theta = \sqrt{5}.$$

$$\therefore \frac{l}{d} = \sqrt{\frac{\cosh 3\theta+1}{4\cosh\theta}} = \left(\frac{\sqrt{5}+1}{2\sqrt{5}}\right)^{\frac{1}{2}}$$
$$= \cdot 850651.$$

DISCUSSION.

Prof. PERRY did not like going back to the idea of magnetic poles in the case of actual magnets. He suggested that the problem proposed by Mr. Blakesley might easily be found by the aid of large scale diagrams of the magnetic lines of force, such as are given in Maxwell. It would only be necessary to draw through the point on the axis of the magnet produced a straight line at right angles to this axis, and to determine the point at which it touched a line of force.

In reply to this the author pointed out that it would be extremely difficult to determine the touching point with any exactness.

Prof. S. P. THOMPSON did not think there was any such thing as a definite distance between the virtual poles of a magnet, but that this distance depended upon the special circumstances of the experiment. He had been led to this result by some experiments in which he had observed the deflection of a magnetometer needle by two different sets of magnets. The result of the two sets of determinations gave different values for the distance between the virtual poles of the magnetometer needle.

Prof. AYRTON thought that the expression "pole of a magnet" was only definite when the special circumstances of the experiment were exactly defined.

Prof. S. P. THOMPSON considered that the magnetic pole must be definite in position, provided the magnet were not acted upon by any external magnetic force, because in that case the surface distribution of magnetism was definite. The distribution, however, would not be centrobaric except in the case of a long thin magnet.

Mr. BAILEY thought that the real way of looking at the question was that in the neighbourhood of one point the lines of force approximated to those which would result from a pair of poles fixed at a certain pair of points, while the field in the neighbourhood of some other point would approximate to that due to a differently situated pair of poles.

## MEETINGS OF SCIENTIFIC SOCIETIES, &c.

**FRIDAY, December 12th.**

Physical Society.

*5 p.m.* Papers to be read: "Some Experiments with Selenium Cells," by Shelford Bidwell, F.R.S.; "Note on Electrolysis," by James Swinburne; and "Alternating Current Condensers," by James Swinburne.

**MONDAY, December 15th.**

Society of Arts.

*8 p.m.* Cantor Lecture I. 4. "Gaseous Illuminants," by Prof. Vivian B. Lewes.

**TUESDAY, December 16th.**

Institution of Civil Engineers.

*8. p.m.* Ordinary Meeting. Papers to be further discussed: "The Lansdowne Bridge over the Indus at Sukkur," The New Chittravati Bridge, Madras Railway."

**WEDNESDAY, December 17th.**

Royal Meteorological Society.

*7 p.m.* Papers to be read: "Note on a Lightning Stroke presenting some features of interest," by Robert H. Scott, F.R.S.; "Note on the effect of Lightning on a Dwelling House," by Arthur Brewin, F.R.M.S.

Society of Arts.

*8 p.m.* Ordinary Meeting. Paper to be read: "Impressionism in Photography," by George Davison.

**THURSDAY, December 18th.**

Chemical Society.

*8 p.m.* Paper to be read: "The Theory of Dissociation into Ions and its consequences," by G. S. N. Pickering.

# The Electrician.

**Published every Friday, Price Fourpence; Post Free, Fourpence Halfpenny.**
**Editorial, Publishing, and Printing Offices:**
**SALISBURY COURT, FLEET ST., LONDON, E.C.**
*Telephone No.* 2714. *Telegrams:* "ELECTRICIAN NEWSPAPER, LONDON."

*All Letters relating to Subscriptions, Advertisements and other business matters should be addressed to the Publisher,* "THE ELECTRICIAN," *Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* "THE ELECTRICIAN" *Printing and Publishing Company, Limited, and be crossed* "*Coutts and Co.*" *All other letters to be addressed to the Editor.*

*All letters intended for insertion in* "THE ELECTRICIAN," *or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever will be taken of anonymous communications.*

"THE ELECTRICIAN" *is published every Friday morning, in time for the morning mails. Subscribers should receive their copies by the first post on Friday morning.*

"THE ELECTRICIAN" *is on sale at the railway bookstalls throughout the Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices as above.*

*New Volumes of* "THE ELECTRICIAN" *commence in May and November.*

## SUBSCRIPTION RATES.

The rates for Subscriptions to "THE ELECTRICIAN" are as follows:—

| | 3 months. | 6 months. | 12 months. |
|---|---|---|---|
| | s. d. | s. d. | s. d. |
| For the United Kingdom | 5 0 | 10 0 | 19 6 |
| For Foreign Parts and Colonies:— | | | |
| Within Postal Union | 6 6 | 12 6 | 24 0 |
| Aden, Borneo, Ceylon, China, India, Japan, Java, Labuan, Mozambique, New Caledonia, Persia, Philippine Islands, Siam, Transvaal, and Zanzibar | 7 6 | 14 6 | 28 0 |

## TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has by far the largest circulation of any English Electrical paper, and circulates all over the World.**

*Particulars relating to Advertisements will be promptly forwarded on application to the Offices as above.*

TRADE ADVERTISEMENTS *intended for the current issue must reach the Offices not later than First Post on Thursday morning. Renewals of expiring advertisement orders and alterations to standing advertisements should be in the Publisher's hands by Wednesday at latest. No alteration can be made in Wrapper advertisements after Wednesday evening.*

SMALL PREPAID ADVERTISEMENTS *(for Rates see page xvii.) are accepted up to 4 p.m. on Thursday.*

## TECHNICAL PRINTING.

"THE ELECTRICIAN" PRINTING AND PUBLISHING COMPANY (LIMITED) *inform Electricians, Electric Light Engineers, &c., that they make a specialty of Technical Printing, and have a large Staff thoroughly acquainted with Electro-Technology. They can, therefore, promise Accuracy and Despatch in the Printing of Electro-Technical Literature, &c.*

## "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. (Royal 8vo.)

*Early in each year is issued* "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. *The* DIRECTORY *was established in 1883, and the 1890 Edition consisted of about 850 pages of printed matter. The names and addresses of all persons engaged in the Electrical Industries at home and abroad may be relied upon as accurate. Useful Tables and Electrical Formulæ, and information specially compiled for this work are given, together with popularly-written Biographical Notices of the leading Electricians, Electrical Engineers, &c., accompanied in many cases by Portraits.*

*Orders for the 1890 issue should be forwarded* AT ONCE *to the Publishing Offices, Salisbury-court, Fleet-street, London, E.C.*

*The 1891 Edition is now preparing, and New Names, &c., can now be received.*

## ELECTRICAL BOOKS AND PUBLICATIONS.

*All Books, Newspapers, and other publications, dealing with Electrical and kindred subjects, can be ordered direct of* "THE ELECTRICIAN" *Printing and Publishing Company, who are proprietors of the well-known* "ELECTRICIAN" *Series of Standard Electrical Works, and are agents for all the leading publishing houses at home and abroad.*

## THE INSTITUTION OF ELECTRICAL ENGINEERS.

A special general meeting of the Institution of Electrical Engineers, to which members only were admitted, was held last night for the purpose of considering a resolution for the alteration of the tenth, twelfth, and twenty-second articles of association, with the intention of confirming it at a subsequent meeting. The meeting being announced for 7.45, a quarter of an hour before the general meeting, suggests that it was expected that there would be very little to say about the proposed changes. This expectation was, indeed, justified by the nature of the amendments which, considering their aim and intention, are of somewhat disappointing character. The connection between this Institution and the Institution of Civil Engineers is more intimate than appears at first sight. Not only are its ordinary meetings and its council meetings held in the home of the latter body, but a considerable portion of the audience is composed of members of the older society who, being entitled to attend the meetings of other societies, do not trouble to become members of the lesser institutions. In view of this relationship and of the immense prestige and importance of the Institution of Civil Engineers, which is due to its admirable management rather than to its mere seniority, it is not surprising that the junior societies should both recognise their shortcomings by comparing themselves with such a standard, and seek, as they grow, to introduce improvements suggested by it.

The first of these articles, according to the proposed amended form, provides that associates shall, except in the case of those transferred from the class of students, be persons of more than twenty-one years of age; the second permits a student (who may enter at an earlier age than that of eighteen, which was specified under the old rules) to be eligible for transfer from the class of students to the class of associates two years after his election, and, "if not so eligible for transfer at the

Digitized by Google

end of three years from the date of his election he shall, if he have then attained the age of twenty-one years, and otherwise on attaining that age cease to be a student of the Institution, or to be otherwise connected therewith." The profession of electrical engineering is very remarkable for the number of youths who profess to be, and indeed are, "electrical engineers." Any stranger attending the meetings is at once struck by the youthful character of the audience, and might reflect whether there can be any possible connection between a young science and the age of those who are occupied with it.

It has been stated, and with good reason, that an electrical engineer should first be a mechanical engineer, and should then take up electrical science. We cannot expect every young man who intends to be an electrical engineer to go through a three years' pupilage at a regular engineer works, and to devote his attention to the general construction of machinery, without spending much, if any, time on the study of electricity. Few can afford to lose so many years; but those that can will never regret the training. There are too many "electricians" and too few who can really be called electrical engineers; and the fact that the Institution which should do all in its power to encourage sound training, appears to assume that the stage of studentship should cease at so early a period is much to be regretted. Why should so young an electrical engineer consider himself a qualified member of his profession, which embraces both mechanical and electrical science, when the Institution of Civil Engineers orders that associate members shall be more than twenty-five years of age, and allows its students to continue in that stage until they attain the age of twenty-six years? The old Article 10, dated May, 1883, limited associates to persons of more than twenty-one years of age; the new rule does not permit men to become associates earlier than formerly, but it allows students to enter at an earlier age, in fact, no particular age is mentioned. On the other hand, it permits anyone who has begun to study electrical science or engineering at a later period in life to join the Institution. He could not do so as an associate, being without the necessary qualification, but he can be admitted as a student. If this will really benefit the Institution and its junior members, we should be among the first to welcome it.

The remaining amendments at present proposed appear to relate merely to entrance fees and minor points arising out of the alterations. The admission of students demands no severe conditions. They must be either serving a pupilage to an electrical or telegraph engineer, who need not (as with civil engineers) be a member of the Institution, or they may be merely "studying electrical science or telegraphy." Pupilage in electrical engineering is already in a very lax condition, and is in some cases neither creditable to the employer nor useful to the pupil. It is with anything but radical principles that we would hail with satisfaction some much more important reforms than this one of junior or student membership. The *members* should be individuals who are properly entitled to write the mystic letters M.I.E.E. after their name. Everyone who actually is, or who is in the process of becoming an "electrical engineer," should be allowed to participate in whatever benefits may accrue from reading the journal and listening to the debates. Members are, however, more substantially benefited, and extreme care should therefore be taken to keep this class not exclusive, but select. And we think that the time has come when something more should be asked of candidates for admission as associates than that they should be "connected with electrical or telegraphic science or engineering, either professionally or otherwise, or who are so intimately associated with electrical or telegraphic science that the Council consider their admission as associates would conduce to the interests of the society." Our friends the plumbers are useful members of society, and with commendable enterprise they are "taking up" electrical engineering, but are they as useful to the Institution as the Institution membership is to them? A versatile tradesman in Paddington calls himself "architect, builder, undertaker, gas, hot water, and electrical engineer." We know of an electrical engineer who was asked to give his advice on sanitary work; but how many associates of the Institution would not be accurately described by the graceful term "sanitary engineers." The "personal knowledge" is a very informal matter with the electrical body, while it is a somewhat important condition in election to corporate membership, whether associate or otherwise, of the Institution of Civil Engineers, since the signatures of five members are required other than those on the council.

There are two sides to this question. Some would welcome all who contribute by their work to the practice or advancement of the electrical industry, from the highest to the lowest, from the stoker, whose conscientious services are essential, to the company promoter, who is a necessary evil. Others would object, with no small reason, that neither these individuals nor the "sanitary engineer" can be said to *be* electrical engineers in any sense. Although they may be "connected with electrical . . . engineering." Selfish as it may appear to some, we would advocate the well-being of the Institution rather than that of those who seek to become members. Architects, surveyors, patent agents, and many other professions, such as dentists, have all prescribed conditions and qualifications for membership of a distinct body; chemists are talking of doing the same. We do not, at present, go as far as this. It savours rather too much of the mystery and exclusiveness of the old guilds and craftsmen. Individuals can or ought to take care of themselves. What we wish to see improved is the Institution of Electrical Engineers.

## THE INSTITUTION OF ELECTRICAL ENGINEERS.

At the annual general meeting of the Institution of Electrical Engineers held last night, the following members of council were elected for the year 1891:—

**Council for 1891.**

*President.*

W. Crookes, F.R.S., Past President Chem. Soc.

*Vice-Presidents.*

| | |
|---|---|
| Prof. W. E. Ayrton, F.R.S. | R. E. Crompton, M.Inst.C.E. |
| Alexander Siemens. | Sir David Salomons, Bart., M.A. |

*Members of Council remaining in Office.*

| | |
|---|---|
| Sir James Anderson. | Gisbert Kapp, Assoc.M.Inst.C.E. |
| Sir Albert J. L Cappel, K.C.I.E. | Sir Henry Mance, C.I.E., M.Inst.C.E. |
| Major Philip Cardew, R.E. | Prof. Silvanus P. Thompson, B.A., D.Sc., F.R.A.S. |
| Sir James Douglass, F.R.S. | |
| Colonel R. Raynsford Jackson. | |

*New Members of Council.*

| | |
|---|---|
| Major G. W. Addison, R.E. | Professor George Forbes, F.R.S.S (L. & E.). |
| Prof. J. A. Fleming, M.A., D.Sc. | W. M. Mordey. |

*Associate Members of Council.*

| | |
|---|---|
| I. Probert. | R. W. Wallace. |
| Captain A. M. Stuart, R.E. | |

It was announced in the course of the reading of the annual report that the Institution Premium had been awarded to Mr. W. B. Esson for his paper "On Some Points in Dynamo and Motor Design," the Paris Exhibition Premium being awarded to Mr. W. H. Melhuish for his paper "On Signalling Across Rivers in India," and the Fahie Premium to Mr. K. L. Murray for his Paper on "The Electric Lighting of the Melbourne Exhibition."

It was also announced that the offices of the Institution would shortly be transferred to 2, Victoria Mansions, owing to the expiration of the lease of No. 4, The Sanctuary.

## REVIEWS.

**A Treatise on Electro-Metallurgy.** By WALTER G. McMILLAN, F.I.C., F.C.S. (Charles Griffin and Co., Exeter-street, Strand.) Series: Griffin's Scientific Text-books.

It is perhaps no part of the duty of a critic to suggest to an author that he ought to have written a different class of book from that under review, provided that the author sets out clearly his object and successfully carries it out. In the present case the preface lays down the author's opinion that the subject of this book should be treated from a *technological* rather than from a *technical* standpoint, and from this point of view there is much to commend the book to the student, or as a useful work of reference. So also to the actual worker in electro-metallurgy, who perhaps desires to utilise some additional features of the art, the book will be of service; but if we consider the case of an engineer or electrician called up to carry out some electro-metallurgical operations, this work will not give him much assistance. One feels, in fact, that the author is a chemist, a metallurgist, and perhaps an electrician; but not an electro-metallurgist who knows the difficulties of the subject, and the "wrinkles which enable these to be overcome.

In the purely electrical part of the work various more or less obsolete dynamos are described, whilst many very popular forms, used much in Birmingham and other metal-working centres, are not mentioned. We wonder, by-the-way, seeing how the Brush machine with "a teazer" figured in the recent compound winding case, whether any of these machines are doing practical work in this country for electro-metallurgical purposes? There are in the course of the book many valuable tables and details as to solutions, their strengths, and the current densities required for their proper working, but these would be much improved if their specific resistances at the working temperatures, together with the volts required to overcome the action of polarisation, were stated. The author gives some interesting notes relating to the historical part of the subject, and figures, we observe, also in a prophetic *rôle*, when, on page 147, speaking of the Elmore process, he says, "the application of the principle may be expected to develop, perhaps, in other directions than those at present contemplated." So far his words have proved startlingly correct. Can he now tell us what is to follow "the Trust?"

**Impianti di Illuminazione Elettrica.** By EMILIO PIAZZOLI. (U. Hoepli, Milan, 1891.)

This manual, for those who may either have to equip or look after a central station for lighting, is intended to fill up the gap left between scientific works on electricity on the one side and popular treatises on the other. The opening chapter gives the principal points of the theory clearly and concisely, although a few sacrifices have been made for the sake of simplicity. In the chapters on the practice, the advisability of inserting makers' price lists is open to question, though, considering the object of the book, there is a great deal to be said in favour of their admission. At the same time, in the dynamo list a column giving the floor space occupied by the various machines would be of more practical use than that showing the price per kilogram. Also some of the space at present devoted to primary batteries might with advantage be occupied by particulars of some of the types of steam and water motors. In spite, however, of a few such defects in arrangement, the work on the whole is an excellent one, and is well worthy of a place amongst the books of the English as well as of the Italian engineer. The chapters on conductors in particular will be found extremely useful.

## CHARGE AND DISCHARGE CURVES OF SECONDARY CELLS.

We are indebted to Mr. Crompton and Mr. Reckenzaun for the following diagrams, referred to by them in the discussion on Prof. Ayrton's Paper on the "Chemistry of Secondary Cells."

Figure 1 is a series of discharges taken at different rates from an eleven-plate Crompton-Howell cell, the plates being approximately 8 × 8 × ½in. thick. These are the plates that have been and continue to be used for the regular batteries for central station work. The figures under each curve show the rate at which the cell was discharged, namely, from 11 amperes up to 66 amperes, or at the rates of 1, 2, 4, 5, and 6 amperes per plate. The reduction of capacity in the cell by heavy rates of discharge is very remarkable. In these experiments no attempt was made to see to what extent a second discharge, if any, could be obtained from the cell, but such second discharges can be obtained in every case, and the amount of the second discharge is in proportion to the amount which the original discharge fell short of what is known to be the capacity of the cell when discharged at low rates. It will be noted that in this case the form of the curve is very definite; the downward bend, as soon as the E.M.F. falls to 1·8, being very rapid.

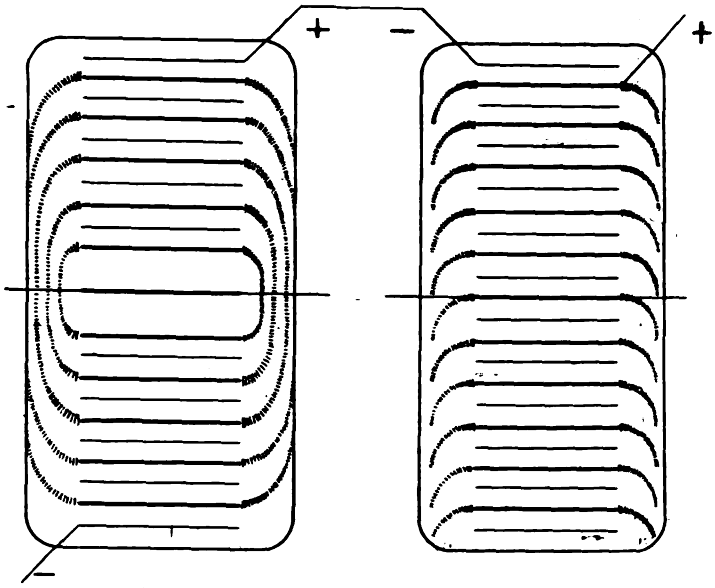

FIG. 3.—Diagram showing Colouration Curves in the Electrolyte of a Crompton-Howell Cell.

Figure 2 shows the result of a similar set of experiments applied to a cell of approximately the same capacity, but made up of only seven plates, these plates, however, being increased in thickness, so that the weight of the seven plates was exactly the same as the 11 plates of the first cell. In this case the loss of capacity is even more marked than in the former, and the shape of the curve is somewhat different. The advantage of these thicker plates is that they are mechanically very strong, and the cell is more quickly put together, and is in many respects easier to handle.

The discolouration shown in the two cells M and L (Fig. 3) is very peculiar. That in M appears to consist of a series of claret coloured bands or shells apparently extending from the surface to the bottom of the electrolyte. These bands have very sharply defined edges, and the space between them is perfectly clear and free from discolouration. The bands are shown connecting both edges of the positive plates. In cell L, where, it will be observed, the circuit is completed at one end only of the cell the positive plates showed a series of grooved horns. The edges of these horns were sharply defined, but the extremities when seen from above had the appearance of brushes. Besides the two arrangements shown this discoloration arranges itself in many other forms, sometimes in that of horizontal strata of varying thicknesses, but in all cases there is a very sharp line of demarcation between the clear liquid and the coloured liquid.

In spite of Mr. Swinburne's and other gentlemen's remarks, Mr. Crompton states that analysis shows no trace of permanganic and ferric gases, the only thing present being very minute traces of gold. Mr. Crompton is, therefore, led to believe that the phenomenon is due to very minute traces of metallic gold, suspended in the liquid in a state of almost infinitely fine division, the colour corresponds very closely with what one would expect from gold in this state.

## NOTES ON THE CHEMISTRY OF SECONDARY CELLS.*

By Professor W. E. Ayrton, Vice-President; C. G. Lamb, B.Sc., and E. W. Smith, Associates.

DISCUSSION. (Authorised Abstract.)

Dr. GLADSTONE said, in opening the discussion, he had been greatly interested in the points brought out by the authors, and in the account of the elaborate experiments described. He was rather surprised that taking out so many plugs from the cell had not greatly damaged it. The chemical results arrived at, he considered, confirmed the views put forward by himself and Mr. Tribe about nine years ago, as to the action of cells, resulting in the formation and reduction of ordinary lead sulphate. Since that time, however, many statements had been made attributing important functions to subsulphates, but so far as he and Mr. Hibbert had investigated the matter, such statements had not been confirmed. They now believed that the so-called subsulphates are probably mixtures of ordinary sulphate and peroxide. Referring to the difficulty experienced by Mr. Robertson in analysing the powdered sulphate, he pointed out that ammonium acetate could be used for dissolving out the sulphate. Results obtained by this method showed the sulphate to be the normal one, and he did not think the solvent would alter any subsulphates if such were present. In his opinion there could be no doubt but that the sulphate surrounding the granules of peroxide would act as stated in the paper, and diminish the capacity of the cell. Speaking of the gas given off by the negative plate, he said the fact had been alluded to in a paper by Mr. Hibbert and himself recently published in the *Phil. Magazine*. They, however, had not observed the great differences in the hardness of plugs at different parts of the plates. This result he considered very important, and thought it would lead to a modification in the form of plates.

Mr. CROMPTON said that for some time past he had been working on the subject of secondary cells, and had arrived at results similar to those brought forward in the paper. One great advantage, however, of the results contained in the communication under discussion, arose from the fact that they were obtained from cells of a different type from those he had experimented on, for if he himself had brought the results before the Institution, it would have been thought that the actions were peculiar to his kind of cell. As regards the gassing of cells, he had found it due in a great measure to light. Both sun-light and arc-light increased this action, and quantitative experiments were now being made. He was glad to see the statements of the advocates of secondary batteries, as regards efficiency, had been confirmed. They had, he said, been accused of exaggerating their efficiency, and not without cause, for the cells themselves behave peculiarly, as, for example, the 105 per cent. quantity efficiency mentioned in the paper. Such results seem impossible, and, showed the necessity of getting cells into what the authors had called "the steady working state." He regretted that "proof plates" had not been used in the experiments on the running down of cells. He had used them for a long time, and always found the negatives discharged first. If, however, very thick negatives were used, there was no sudden drop in the potential difference, such as indicated in Figs. 2 and 3. In endeavouring to measure the resistance of the cells with a view to determining the best proportions of plates and liquid, he had met with great difficulties, and he now believed that what is usually measured is of the nature of a back E. M. F.; this he supported by saying that the so-called resistance did not seem to vary, either with the thickness of the plates, or their distance apart, or with the density of the acid. During his investigations a rosy colouration of parts of the liquid had been noticed in some cells; the coloured portions may either appear as strata, lines, or in tree-like forms, and in some cases resemble the shapes of magnetic lines of force. These peculiarities, he hopes, may give some idea of the electric stresses and strains within the electrolyte. The recuperative power of discharged and reversed cells was very marked, for he had observed it in cells that were half charged in the reversed direction, and on cutting up the plates, layers of different materials could be seen. This fact shows how important it is to thoroughly charge cells of the Planté type during formation by reversals. Until quite recently negative plates had been considered faultless, and the positives blamed for defects which were in reality due to imperfections in the negatives. He knew of no case in which positives had gone bad when their negatives had sufficient capacity, and for this reason the negatives ought to be made thicker or larger than the positives. "Sick cells," he said, get partially sulphated and the negatives run down; when the E. M. F. falls below 1·3, heavy sulphating of the positive occurs, and so-called "irreducible sulphate" is formed. In his opinion the reducibility or irreducibility is merely a question of its position, or of its contact or want of contact with the conducting material. In conclusion, he suggested that E. P. S. cells might be improved by reducing the size of the plugs, so as to bring the active material closer to the lead backing.

The discussion was adjourned to the 27th inst.

Thursday, November 27th.

Mr. CROMPTON directed attention to three diagrams which he had prepared since last meeting. One of these showed the character of the colouration seen in the electrolyte when viewed from the top. Curved lines or shells start from the positive plates and turn away as if repelled from the cell terminals. In one cell, which had its + and − terminals at opposite ends, the lines curved towards the middle of the cell, whilst in another, where the terminals were both at the same end, they bent towards the opposite end. The second diagram exhibited the influence of the rate of discharge on the capacity of a cell having eleven 5lb. plates. When discharged at one ampere per plate, its capacity was 300 ampere hours; but at six amperes, only about half. The fall of volts was very sudden at the end of each discharge. The third diagram related to the discharge of an experimental cell containing seven 9lb. plates, and showed that, although the capacities were not very different from those of the eleven-plate cell, the fall in volts was not nearly so sudden.

Mr. RECKENZAUN said the papers under discussion were very important ones, and contained much that had never been published before; many of the facts, however, were known to those engaged in the manufacture. The question of efficiency, he thought, was not likely to be settled, since, according to the authors, it may vary between 105 and 58 per cent., depending on the previous history of the cells. In his own experiments on the effect of prolonged rest, he had found a similar loss of efficiency, and he believed this to be due to sulphating of the negatives. The negatives were always played out first, and this defect could not be got over by making them abnormally thick, or by increasing their surface; for if thickening be tried, the interior is not acted on, whilst greater surface gives no advantage on account of the material being at different distances. To test the deficiency of negative plates, he had discharged cells as low as possible, and then put the positive with a newly charged negative; from these a fair E.M.F. and discharge were obtained. He had also tried amalgamated zinc instead of a newly charged negative, and got 40 per cent. of the original capacity. These facts account for the existence of 30 per cent. of $PbO_2$ in the positive plugs when the cell was supposed to be completely discharged. In his opicion it would be better to say that the negatives discharged about 30 per cent. too soon. The negative of Planté cells, especially those formed by the nitric acid process, soon lose their virtue, and this was attributed to the difficulty in removing all the forming acid. In the course of his remarks, Mr. Reckenzaun said he had received a very interesting diagram from his brother in America, showing the E.M.F. current, density of acid, temperature of cell and of surrounding air, &c., during the charges and discharges of a secondary battery. This diagram he would place in the hands of the Secretary.

A communication from Mr. Hall was then read. This related to a pair of E.P.S. plates recently taken from the battery under his charge at the P. and O. Company's Offices, where they had been in constant use for six years. During that period the cells had supplied about 150,000 ampere hours, and were still in good condition, as was indeed evident from the appearance of the plates shown. His experience confirmed the observations of the authors on the effect of rest. In the working of the battery the density of each cell had been carefully watched, and any defect promptly removed.

Mr. W. HIBBERT, referring to the Edinburgh Paper, said he would first deal with the explanation of the high E.M.F. at the end of a charge and its rapid fall on breaking the circuit. In a communication made to the Physical Society last June, Dr. Gladstone and himself had shown reason for believing this to be due to concentration of acid about the positive plate and its subsequent rapid diffusion, and he thought the results plotted in Fig. 4 of the paper under discussion, showing the effect of making and breaking the circuit of a charged cell on its E.M.F. and P.D., were consistent with this idea. Further on in the same paper the authors say that the concentration hypothesis will not explain the rise of P.D. in a cell discharging after a long rest. On this point he, Mr. Hibbert, said that the reaction in such states were very complex; but still, he thought it would be possible to find an explanation of this phenomenon based on similar lines. Referring to the later paper, he thought the authors had rather exaggerated the effect of peroxide on the negative plate in causing the volts to fall, for, in his own experiments, only a small quantity was formed. The simultaneous weakening of the acid round the plates would tend to give a rapid fall in the E.M.F. and the effect of both these actions must be studied if the subject is to be properly understood.

Dr. E. FRANKLAND said he had read the papers with great interest and considered them most important contributions on the subject. In one place the authors deplore the lack of knowledge of the chemical actions in cells, and not without reason. He, however, thought physicists were more to blame than chemists, for the physical actions could be readily determined, whereas the chemical changes present formidable difficulties. The substances used and produced were mixtures, and it was very difficult to separate and analyse them, without producing decompositions. A valuable part of the communications was that relating to the quantity of $PbO_2$ formed and decomposed during the working of cells. On this point he thought the values put down for $PbO_2$ may be either the sesqui—or the three-quarters oxide; and, in fact, the crux of the whole subject lay in the exact nature of the compound formed. Dr. Gladstone and himself had, apparently, arrived at different conclusions, but their differences might admit of explanation, if care and time were taken in considering the matter. Another important point was the quantity of $SO_3$ absorbed during discharge, viz., 3·08 grammes per ampere-hour. If this be translated into hexabasic acid, which he believed to be present, it gives 5·71 grammes. From his own experiments on a 10-plate cell, he had found about 4·7 grammes of hexabasic acid absorbed per ampere-hour, whilst discharging

* Paper read before the Institution of Electrical Engineers on Thursday, November 13, 1890

Digitized by Google

at an E.M.F. averaging 1·9 volts; but when the cell was run down and discharged at an E.M.F. averaging 0·3 volt, he found the rate about 3·3 grammes. He did not wish to put these numbers in conflict with those obtained by the authors, but he was strongly impressed with the idea that the two different quantities, 4·7 and 3·3, pointed to the existence of two distinct chemical reactions, one resulting in an E.M.F. of about 2 volts and the other of ·3 volt.

Mr. F. KING said the results of the tests were very gratifying to the makers of cells. He commended the skill and ingenuity displayed in devising the automatic apparatus, for the labour involved in working a laboratory day and night without such apparatus is enormous. The inequality of current distribution over the surface of the plates was, he said, well known, and the hanging type of cell was devised to remedy this defect. The first form of this type was abandoned, but more recently they had made another form, one of which was exhibited at the meeting. The current is led into the positives at two points on the top and leaves the negatives at the bottom. With this cell they had doubled the normal rate of discharge without diminishing the capacity, and also obtained a longer life. Moreover, the loss of capacity for high rates of discharge, due to the shrinkage of the negative paste, and which is so marked in ordinary types, had been avoided. The positive plates somewhat resemble those of the Tudor cell, having deep horizontal grooves along each side in which the active material is placed. The negatives are made according to Sellon's invention, in which a kind of double grid is used, the parts being displaced diagonally, so that each plug on one side communicates directly with four plugs on the opposite side, and through them with every other plug in that division of the plate. This construction causes any shrinkage of the paste to bind itself more firmly on the grid. As a result of tests on the new cell it has been found that the capacity is greater after 500 or 600 discharges than at the beginning, whereas that of ordinary cells is considerably reduced by 400 discharges. The life of negative plates he believed was not well understood, but with reference to positives he said that those used on tramcars (9 plates 8in × 5¼in.) had a useful life of 70,000 ampere-hours. After one year's use their capacity is reduced 33 per cent. Speaking of the resistance of battery connections, he pointed out the advisability of burning the lugs together so as to give as complete a metallic surface as possible. Respecting the pasting and formation of E.P.S. plates referred to in the second paper, he said that the particulars there given were totally wrong.

Mr. SWINBURNE thought there had never been any valid reason for doubting the formation of normal lead sulphate. The old ideas about reduction and oxidation, &c., had obscured the subject until Dr. Gladstone and Mr. Tribe brought people to order about eight years ago. The difficulty of reducing ordinary sulphate electrically had been given as a reason why it could not be formed, but now its reduction, or non-reduction, was known to be a mere question of making contact with it. Seven years ago he had brought forward a theory that the sulphate is not a secondary product at all, and that the output of a cell is is mainly dependent on the affinity of sulphion for lead. This, together with the other chemical actions, leaves some E.M.F. to be accounted for by Peltier effects, and these effects would show in the temperature coefficient. He was not aware whether calorimetric data had been obtained for the sub-sulphates which Dr. Frankland supposed to be present, but if so, then by working backwards, evidence for or against their existence might be procured. The action of finely-divided lead on sulphuric acid had, he said, been known for years, and this limited the best strength of acid to about 1 in 4. As regards the equilibrium between the plates of a cell, he was inclined to attribute this either to the absence of $PbO_2$ from the positive, or of spongy lead from the negative, rather than to the presence of $PbO_2$ on both plates. He also thought the percentage of material really active was much less than that stated in the paper, for in some experiments of his own he had only found about five per cent. useful. Speaking of Mr. Crompton's colour observation, Mr. Swinburne said they were due to ferric acid formed by the action of $PbO_2$ on iron salts in the commercial acid. In his opinion, the virtues of sulphate of soda had been greatly exaggerated, and he believed its action to be due to its enabling bad contact sulphate to be reached more easily.

Sir D. SALOMONS said he had noticed colourations in one or two of his cells, but had attributed them to impurities. The unequal action on different plugs had been to him a subject of common remark, and he had taken steps to equalise the distribution of current by burning on strips of lead, with good results. The bending of negatives could be prevented by building up the sections rigidly. His experience with soda differed from that of Mr. Swinburne, for he had found caustic soda in the proportion of one ounce to nine gallons very advantageous. Cells supplied with this electrolyte had been left charged for six weeks without injury, and had commenced to boil freely ten minutes after the charging current was started. With ordinary acid two or three hours' charging would be required to produce the same results. In his opinion makers give extreme limits for the so-called normal working rate of cells; and if these were divided by two or three, better results would be obtained, and would be cheaper in the long run. As regards efficiency, he thought 70 per cent. to be a very fair average. The large amount of $PbO_2$ not acted on resulted from the interior of the plugs being, as it were, waterproofed by the sulphate outside. On this account thick plates possessed little or no advantage. Increasing the quantity of electrolyte, however, gives more capacity up to a certain point; but when the plates are put far apart the loss of volts becomes serious. Speaking of pasting positives with $PbO_2$, he said he had made good plates in this way by using very strong acid (nearly pure) in making the paste.

Mr. BERNARD DRAKE, whilst adding his testimony to the value of the papers, thought he ought to mention one or two points of detail which might lead to wrong conclusions. For example, the loss of efficiency, due to rest, might lead clients to suppose that their cells ought to be used even when they were away from home. This, he said, would be a great mistake, for the loss of capacity is due to the negatives, whereas the repairs were chiefly restricted to the positives, whose lives are inversely proportional to the amount of use. In a paper read before the British Association in 1886, he and Mr. Gorham had shown that the whole success of storage cells depended on whether the positives could be made to last a reasonable time, and to effect this, it had been found necessary to overcharge them. The actual plates sent by Mr. Hall from the P. and O. offices had been badly sulphated some time ago, and were condemned; he, however, recommended overcharging, with the result now known. In these cells the density of acid used to be from 1,350 to 1,400, and although he did not now recommend such a high specific greatly, yet he thought the subject required more attention than it had received. As to the proportions of the plates, he said the negatives were intentionally made to give out first, so that the positives might not be run down, for a kind of protecting coating is formed on the positives by charging, and this is removed by discharging them below a certain point. If this coating is continually re-formed, the plates expand and buckle, and the plugs eventually drop out. Speaking of the cooling action during discharge and also after charging has commenced, he did not see any explanation excepting perhaps that it might depend on the same cause as the rise of specific gravity which occurs after charging has stopped. This he had found to be due to the heavy acid, formed during charging, falling to the bottom of the cell, and afterwards diffusing into the general body of the liquid, thus affecting the hydrometer. In this connection he inquired whether the temperature was taken at the top or bottom of the cells. The rise of E.M.F. during the first part of a discharge after rest he attributed to the surface of the negatives being coated with a sulphate, which was reduced by the discharging current. In reference to the shrinkage of negatives, mentioned by Mr. King, he said, that in order to avoid blistered negatives a mixture of litharge and sulphate had been used for pasting, instead of litharge only. This method, although it prevented blistering, necessarily left the plugs of a porous nature, and was liable to permit shrinkage.

The discussion was adjourned to December 11th.

## THE ELECTRO-MAGNET.*

BY PROFESSOR SILVANUS P. THOMPSON.

*(Continued from page 154.)*

### EFFECT OF USING CONED PLUNGERS.

But now if, instead of employing a cylindrical core, you employ one that is pointed, you find this completely alters the position of the maximum pull, for now the point is insufficient to carry the whole of the magnetic lines which are formed in the iron rod. They do not come out at the point, but filter through, so to speak, along the sides of the core. The region where the magnetic lines come up through the iron into the air is no longer a definite "pole" at or near the end of the rod, but is distributed over a considerable surface; consequently when the point begins to poke its nose out, you still have a larger portion of iron up the tube, and the pull, instead of coming to a maximum at that position, is distributed over a wider range. I am now making the experiment roughly with my spring balance and a conical plunger, and I think you will be able to notice a marked difference between this case and that of the cylindrical plunger. The pull increases as the plunger enters, but the maximum is not so well defined with a pointed core as it is with one that is flat-ended. This essential difference between coned plungers and cylindrical ones was discovered by an engineer of the name of Krizik, who applied his discovery in the mechanism of the Pilsen arc lamps. Coned plungers were also examined by Bruger. In Fig. 63 are given the curves that correspond to the use of a coned iron core, as well as those corresponding to the use of the cylindrical iron rod. You will notice that, as compared with the cylindrical plunger, the coned core never gave so big a pull, and the maximum occurred not as the tip emerged, but when it got a very considerable way out on the other side. So it is with both the shorter and the longer coil. The dotted curves in Fig. 64 represent the behaviour of a coned plunger. With the longer coil represented, and with various currents, the maximum pull occurred when the tip had come a considerable way out; and the position of the maximum pull, instead of being brought nearer to the entering end with a high magnetising current, was actually caused to occur further down; the range of action became extended with large currents as compared with small ones. Bruger also investigated the case of cores of very irregular shapes, resembling, for example, the shank of a screw-driver, and found a very curious and irregular force-curve. There is a good deal more yet to be done, I fancy, in examining this question of distributing the pull on an attracted core by altering the shape of it, but Bruger has shown us the way, and we ought not to find very much difficulty in following him.

### Other Modes of Extending Range of Action.

Another way of altering the distribution of the pull is to alter the distribution of the wire on the coil. Instead of having a coned core used a coned coil, the winding being heaped up thicker at one end than at the other. Such a coil, wound in steps of increasing thickness, has been used for some years by Gaiffe, in his arc lamp; it has also been patented in Germany by Leupold. M. Tiève has made the suggestion to employ an iron wire coil, so to utilise the magnetism of the iron that is carrying the current. Tiève declares that such coils possess, for an equal current, four times the pulling power. I doubt whether that is so; but even if it were, we must remember that to drive any given current through an iron wire, instead of a copper wire of the same bulk, implies that we must force the current through six times the resistance; and, therefore, we shall have to employ six times the horse-power to drive the same current through the iron wire coil, so that there is really no gain. Again, a suggestion has been made to enclose in an iron jacket the coil employed in this way. Ironclad solenoids have been employed from time to time. But they do not increase the range of action What they do is to tend to prevent the falling off of the internal pull at the region within the mouth of the coil. It equalises the internal pull at the expense of all external action. An ironclad solenoid has practically no attraction at all on anything outside of it, not even on an iron core placed at a distance of half a diameter of the aperture: it is only when the core is inside the tube that the attraction begins; and the magnetising power is practically uniform from end to end. Last year I wished to make use of this property for some experiments on the action of magnetism on light, and for that purpose I had built, by Messrs. Paterson and Cooper, this powerful coil, which is provided with a tubular iron jacket outside, and a thick iron disc perforated by a central hole covering each end. The magnetic circuit around the exterior of the coil is practically completed with soft iron. With this coil, one may take it, there is an absolutely uniform magnetic field from one end of the tube to the other; not falling off at the ends as it would do if the magnetic circuit had simply an air return. The whole of the ampere-turns of exciting power are employed in magnetising the central space, in which, therefore, the actions are very powerful and uniform. The coil and its uses were described in my lecture last year at the Royal Institution on "Optical Torque."

### Modifications of the Coil-and-Plunger.

In one variety of the coil-and-plunger mechanism a second coil is wound on the plunger. Hjörth used this modification, and the same thing has been employed in several arc lamps. There is a series of drawings upon this wall depicting the mechanism of about a dozen different forms of arc lamp, all made by Messrs. Paterson and Cooper. In one of these there is a plunger with a coil on it drawn into a tubular coil, the current flowing successively through both coils. In another there are two separate coils in separate circuits, one of thin wire and one of thick, one being connected in series with the arc, and one in shunt.

### Differential Coil-and-Plunger.

There is a third drawing here showing the arrangement, which was originally introduced by Siemens, wherein a plunger is drawn at one end into the coil that is in the main circuit, and at the other end into a coil that is in shunt. That differential arrangement has certain peculiar properties, of which I must not now stop to speak in detail. It is obvious that where one core plunges its opposite ends into two coils, the magnetisation will depend on both coils, and the resultant pull will not be simply the difference between the pull of the two coils acting each separately. There is, however, another differential arrangement, used in the Brockie-Pell and other arc lamps, in which there are two separate plungers attached to the two ends of a *see-saw* lever. In this case the two magnetising actions are separate. In a third differential arrangement there is but one plunger and one tubular bobbin, upon which are wound the two coils, differentially, so that the action on the plunger is simply due to the difference between the ampere-turns circulating in the two separate wires.

### Coil-and-Plunger-Coil.

When one abandons iron altogether, and merely uses two tubular coils, one of wide diameter, and another of narrower diameter, capable of entering into the former, and passes electric currents through both of them, if the currents are circulating in the same fashion through both of them they will be drawing into one another. This arrangement has also been used in arc lamps. The parallel currents attract one another inversely, not as the square of the distance, but approximately as the distance. This is one of those little details about which it is as well to be clear. About once a year some kind friend from a distance writes to me pointing out a little slip that he says occurs in my book on electricity, in the passage where I am speaking about the attraction of parallel wires. I have made the terrible blunder of leaving out the word square; for I say the attraction varies inversely as the distance, and my readers are kind enough to correct me. Now when I wrote that passage I considered carefully what I had to write, and the attraction does not vary inversely as the square of the distance, because two parallel wires do not act on one another as two points. They act as two straight lines or two parallel lines, and the attraction between two parallel lines of current, or two parallel lines of magnetism, or two parallel lines of anything else that can attract, will not act inversely as the square, but simply inversely as the distance in between.

### Intermediate Forms.

Now this property of the coil-and-plunger of extending the range of action has been adopted in various ways by inventors whose object was to try and make electro-magnets with a sort of intermediate range. For certain purposes it is desirable to construct an electro-magnet which, while having the powerful pull of the electro-magnet, should have over its limited range of action a more equable pull, resembling in this respect the equalising of range of the coil and plunger. Some of these intermediate forms of apparatus are shown in the following diagrams. Here (Fig. 65) is a peculiar form of electro-magnet; it combines some of the features of the iron-clad electro-magnet with those of the movable plunger; it has a limited range of action, but it is of great power over that range, owing to its excellent magnetic circuit. It was invented, in 1870, by Stevens and Hardy, for use in an electric motor for running sewing machines.

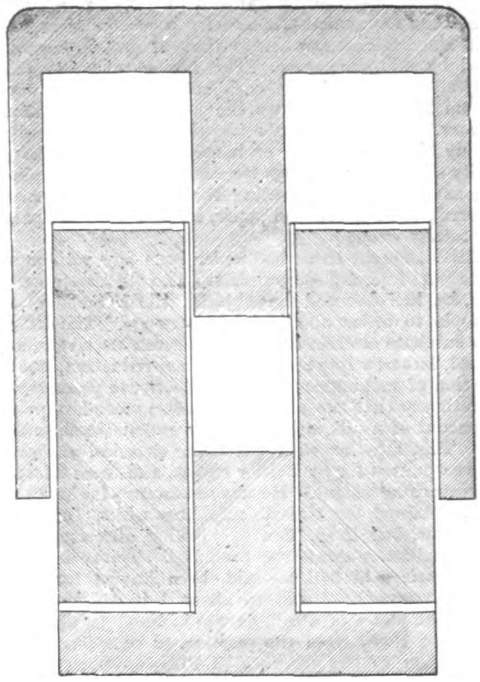

Fig. 65.—Plunger Electro-magnet of Stevens and Hardy.

A very similar form is used in Weston's arc lamp. A form of plunger electro-magnet, invented by Holroyd Smith in 1877, resembles Fig. 65 inverted; the coil being surrounded by an iron jacket, whilst a plunger, furnished at the top with an iron disc, descends down the central tube to meet the iron at the bottom.

Then there is another variety, of which I was able to show an example last week by the kindness of the Brush Company, namely, the plunger electro-magnet employed in the Brush arc lamps. A couple of tubular coils receive each an iron plunger, connected together by a yoke; whilst above, the magnetic circuit is partially completed by the sheet of iron which forms part of the enclosing box. You have here, also, the advantage of a fairly complete magnetic circuit, together with a comparatively long travel of the plunger and coil. It is a fair compromise between the two ways of working. The pull is not, however, in any of these forms, equal all along the whole range of travel; it increases as the magnetic circuit becomes more complete.

There are several other intermediate forms. For example, one inventor, Gaiser, employs a horse-shoe electro-magnet, the cores of which protrude a good distance beyond the coils, and for an armature he employs a piece of sheet-iron, bent round so as to make at its ends two tubes, which enclose the poles, and are drawn down over them. Contrast with this design one of much earlier date by an engineer, Roloff, who made his electro-magnets with iron cores not standing out, but sunk below the level of the ends of the coils, whilst the armature was furnished with little extensions that passed down into these projecting tubular ends of the coils. Some arc lamps have magnets of precisely that form, with a short plunger

Digitized by Google

entering a tubular coil, and met half-way down by a short fixed core inside the tube.

Here (Fig. 67) is one form of tubular ironclad electro-magnet that deserves a little more attention, being the one used by Messrs. Ayrton and Perry in 1882 ; a coil has an iron jacket round it, and also an annular iron disc across the top, and an annular iron disc across the bottom, there being also a short internal tube of iron extending a little way down from the top, almost meeting another short internal tube of iron coming up from the bottom. The magnetic effect of the enclosed copper coil is concentrated within an extremely short space, between the ends of the internal tubes, where there is a wonderfully strong uniform field. The range of action you can alter just as you please in the construction by shortening or lengthening the internal tubes. An iron rod inserted below is drawn with great power and equality of pull over the range from one end to the other of these internal tubes.

### Action of Magnetic Field on Small Iron Sphere.

In dealing with the action of tubular coils upon iron cores, I showed how, when a very short core is placed in a uniform magnetic field, it is not drawn in either direction. The most extreme case is where a small sphere of soft iron is employed. Such a sphere, if placed in even the most powerful magnetic field, does not tend to move in any direction if the field is truly uniform. If the field is not uniform, then the iron sphere always tends to move from the place where the field is weak to a place where the field is stronger. A ball of bismuth or one of copper tends, on the contrary, to move from a place where the field is strong to a place where the field is weaker. This is the explanation of the actions called "dia-magnetic," which were at one time erroneously attributed to a supposed dia-magnetic polarity opposite in kind to the ordinary magnetic polarity. A simple way of stating the facts is to say that a small sphere of iron tends to move up the *slope* of a magnetic field, with a force proportional to that slope ; whilst (in air) a sphere of bismuth or one of copper tends, with a feeble force, to move down that slope. Any small piece of soft iron—a short cylinder, for example—shows the same kind of behaviour as a small sphere. In some of Ayrton and Perry's coiled-ribbon amperemeters and voltmeters, and in some of Sir William Thomson's current-meters, this principle is applied.

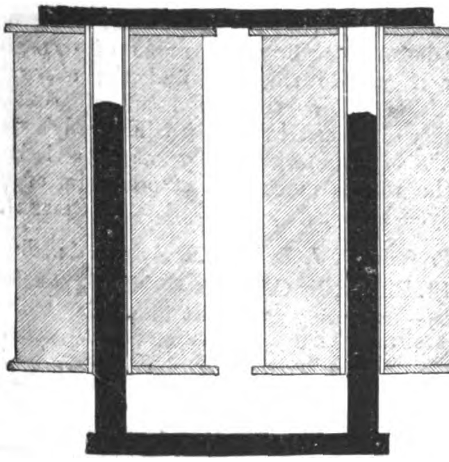

Fig. 66.—Electro-magnet of Brush Arc Lamp.

### Sectioned Coils, with Plunger.

An important suggestion was made by Page, about 1850, when he designed a form of coil-and-plunger having a travel of indefinitely long range. The coiled tude, instead of consisting merely of one coil, excited simultaneously throughout its whole length by the current, was constructed in a number of separate sections or short tubes, associated together end to end, and furnished with means for turning on the electric current into any of the sections separately. Suppose an iron core to be just entering into any section, the current is turned on in that section, and as the end of the core passes through it, the current is then turned on in the section next ahead. In this way an attraction may be kept up along a tube of indefinite length. Page constructed an electric-motor on this plan, which was later revived by Du Moncel, and again by Marcel Deprez in his electric "hammer."

### Winding of Tubular Coils and Electro-Magnets.

The mention of this mode of winding in sections leads me to say a few final words about winding in general. All ordinary coils, whether tubular or provided with fixed cores, are wound in layers of alternate right-handed and left-handed spirals. In a preceding lecture I mentioned the mistaken notion, now disproved, that there is any gain in making all the spirals right-handed or all left-handed. For one particular case there is an advantage in winding a coil in sections ; that is to say, in placing partitions or *cloisons* at intervals along the bobbin, and winding the wire so as to fill up each of the successive spaces between the partitions before passing on from one space to the next. The case in which this construction is advantageous is the unusual case of coils that are to be used with currents supplied at very high potentials. For when currents are supplied at very high potentials there is a very great tension* exerted on the insulating material, tending to pierce it with a spark. By winding a coil in *cloisons*, however, there is never so great a difference of potentials between the windings on two adjacent layers as there would be if the layers were wound from end to end of the whole length of coil. Consequently, there is never so great a tension on the insulating material between the layers, and a coil so wound is less likely to be injured by the occurrence of a spark.

Another variety of winding has been suggested, namely, to employ in the coils a wire of graduated thickness. It has been shown by Sir William Thomson to be advantageous in the construction of the coils of galvanometers to use for the inner coils of small diameter a thin wire ; then, as the diameter of the windings increase, a thicker wire ; the thickest wire being used on the outermost layers ; the gauge being thus proportioned to the diameter of the windings. But it by no means follows that the plan of using *graded wire*, which is satisfactory for galvanometer coils, is necessarily good for electro-magnets. In designing electro-magnets it is necessary to consider the means of getting rid of heat ; and it is obvious that the outer layers are those which are in the most favourable position for getting rid of this heat. Experience shows that the under layers of coils of electro-magnets always attain a higher temperature than those at the surface. If, therefore, the inner layers were to be wound with finer wire, offering higher resistance, and generating more heat than the outer layers, this tendency to overheating would be still more accentuated. Indeed, it would seem wise rather to reverse the galvanometer plan, and wind electro-magnets with wires that are stouter on the inner layers, and finer on the outer layers.

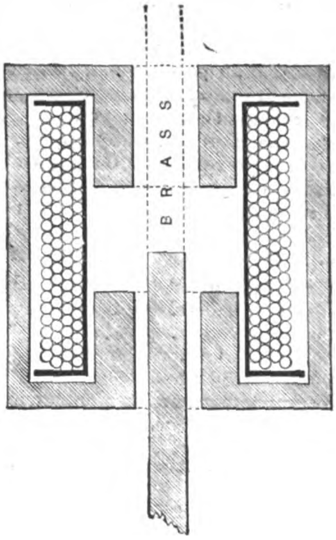

Fig. 67.—Ayrton and Perry's Tubular Ironclad Electro-Magnet.

Yet another mode of winding is to employ several wires united in parallel, a separate wire being used for each layer, their anterior extremities being all soldered together at one end of the coil, and their posterior extremities being all soldered together at the other. Magnetically, this mode of winding presents not the slightest advantage over winding with a single stout wire of equivalent section. But it has lately been discovered that this mode of winding with *multiple wire* possesses one incidental advantage, namely, that its use diminishes the tendency to sparking which occurs at break of circuit.

### Extension of Range by Oblique Approach.

I now pass to the means which have been suggested for extending the range of motion, or of modifying its amount at different parts of the range, so as to equalise the very unequable pull. There are several such devices, some electrical, others purely mechanical, others electro-mechanical. First, there is an electrical method. André proposed that as soon as the armature has begun

* The tension on the insulating material, tending to pierce it with a spark, is proportional to the square of the difference of potentials (per unit thickness) to which the insulating material is subject. It is incorrect to talk about the tension of the conductor or about the tension of the current ; for the tension or electric stress is always an action affecting the di-electric or insulating material.

Digitized by Google

to move nearer, and comes to the place where it is attracted more strongly, it is automatically to make a contact, which will shunt off part of the current and make the magnetism less powerful. Burnett proposed another means; a number of separate electro-magnets acting on one armature, but as the latter approached these electro-magnets were one after the other cut out of the circuit. I need not say the advantages of that method are very hypothetical. Then there is another method which has been used many times with very great success, the method of allowing the motion of the armature to occur obliquely, it being mechanically constrained so as to move past, instead of towards the pole. When the armature is pulled thus obliquely, the pull will be distributed over a definite wider range. Here is a little motor made on that very plan. A number of pieces of iron set on the periphery of a wheel are successively attracted up sideways. An automatic device breaks the circuit as every piece of iron comes near, just at the moment when it gets over the poles, and the current being cut off, it flies on beyond and another piece comes up, is also attracted in the same way, and then allowed to pass. A large number of toy motors have been made from time to time on this plan. I believe Wheatstone was the first to devise the method of oblique approach about the year 1841. He made many little electro-magnetic motors, the armatures of which were in some cases solid rims of iron arranged as a sort of wheel, with two or more zig-zag internal teeth, offering oblique surfaces to the attraction of an electro-magnet. Such little motors are often now used for spinning Geissler's vacuum tubes. In these motors the iron rim is fixed, and the electro-magnet rotates. The pole of the electro-magnet finds itself a certain distance away from the iron ring, it tries to get nearer. The only way it can get nearer is by swinging round, and so it gradually approaches, and as it approaches the place where it is nearest to the internal projection of the rim the current is cut off, and it swings further. This mode may be likened to a cam in a mechanical movement. It is, in fact, nothing else than an *electro-magnetic cam*. There are other devices, too, which are more like electro-magnetic *linkages*. If you curve the poles or shape them out you may obtain actions which are like that of a wedge on an inclined plane. There is an electro-magnet in one of Paterson and Cooper's arc lamps wherein the pole-piece, coming out below the magnet, has a very peculiar shape, and the armature is so pivotted with respect to the magnet, that as the armature approaches the core as a whole, its surface recedes from that of the pole-piece, the effect being that the pull is equalised over a considerable range of motion. There is a somewhat similar device in De Puydt's pattern of arc lamp.

*(To be continued.)*

## AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *November* 28, 1890.

**The Edison Company.**—This company has recently taken the aggressive by cutting prices of all its apparatus to a point far below anything that has previously been reached. This will undoubtedly have the double tendency of increasing its sales and making it very lively for small competitors. Some few of the new Edison arc machines have already been put into use, but it is too early yet to say very much as to the results that have been obtained.

**Electrical Railways.**—Much interest has been excited in this country by the reports of the opening of the City and South London Railway. It will probably not be very long before active efforts are made to adopt the motor for more severe service than street cars in this country. The proposed elevated railroad of the West End Company in Boston will undoubtedly be operated electrically; and the same is probably true of one of the new elevated railroads in Chicago. Now that the way has been pointed it is more than likely that further progress will be comparatively rapid.

**Electrical Execution.**—Next week there will, in all probability, be another electrical execution, this time at Sing Sing Prison. The greatest care has been exercised to avoid the possibility of difficulties like those that attended the Kemmler execution. There will be far less publicity than in the former case, and in allprobability very much less public excitement. The daily papers are taking comparatively little notice of this second execution.

**Railway Headlight.**—I recently saw the electrical headlight, of which much has been heard recently, in operation on a western road. The result of its use is very striking. The light is of the most intense brilliancy, and the track is made almost as bright as day for a long distance in front of the locomotive. The use of this piece of apparatus is extending rapidly, and bids fair to become an important adjunct in railway operation.

## CORRESPONDENCE.

### FORCES BETWEEN CURRENTS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR,—The enclosed letter, which I received a few months ago, but did not then read, you may perhaps choose to insert in your journal, as an attempt to press further some of the analogies between electric and hydraulic currents.

It may, however, be useful if I remark that the stresses and strains mentioned by Mr. Erskine-Murray as existing in an elastic medium through which a liquid is flowing have their analogues in the electro-static actions of currents, and are not immediately and obviously connected with a current's electro-kinetic actions, which depend on a distribution of kinetic energy in the medium, and appear to require something corresponding to spinning wheels for their complete mechanical representation.

May I also take the opportunity of saying that, although in a letter on page 83 of your issue of November 21, I emphasised once more the mode of transmission of energy by cog-wheels as on the average radial, I did not mean to enter into detail regarding the mode of engagement of the teeth; for if we do this, we find the energy-path to be a special form of curve, the locus of contact of pairs of teeth, fully discussed in Professor Kennedy's "Mechanics of Machinery." My remarks apply more strictly to friction gearing—the wheels in contact at one point of their circumference only.—Yours, &c., OLIVER J. LODGE.

*To Professor O. J. Lodge, F.R.S., &c., &c., Liverpool.*

St. Fillans, by Crieff, Perthshire, September 17, 1890.

DEAR SIR,—In reading your most interesting book on "Modern Views of Electricity," I noticed that on page 91, article 40, you say that a certain series of facts about electric currents must be considered *suorum generum*, not having any hydraulic analogue.

Now, there are some things concerning the motion of fluid through cavities in a solid, which, though they may not be strictly analogous, yet appear, to me at least, helpful towards understanding movements of electricity. (Fig. 1).

First and foremost, the phenomena connected with the flow of water do not occur solely *inside* the pipe.

(1.) Consider an indiarubber tube lying on a level surface, and attached at one end to a supply of water at a high pressure, produced, say, by compressing a large elastic reservoir, in which sufficient water is stored. If there be a current of liquid in the pipe, the tension in the walls of it will be greater at a point near the reservoir than at a point near the open end. But this is not quite analogous to the electric case, partly because the electric current is in almost all cases (except submarine cables) surrounded by dielectric, which fills the entire space inside the contour of the current, while the tube is surrounded by air which is dikinetic (transmits energy by diffusion of motion) like an electric conductor.

(2.) Now consider a block of incompressible elastic solid traversed by a straight tunnel of circular section through which a current of incompressible but viscous (in any degree) fluid is made to flow.

First then, the normal pressure on the sides of the tunnel, and consequently the stress in the surrounding solid, will decrease in the direction of flow; also the diameter of the tunnel will be increased by an amount depending on the elasticity of the solid and the normal pressure at the point. The solid will be slightly displaced in directions normal to the surface of the tunnel, and perpendicular (very nearly) to its central axis.

Secondly, since the liquid is viscous, there will be a tangential force on the surface of the tunnel, causing a shear in the surrounding solid. This stress will be the same per unit surface all along the tunnel if the tunnel be not appreciably conical.

Consider now the effect of this shear on the solid medium, and through it on any other tunnels or cavities containing fluid that may exist in the block. Suppose the block infinite in size.

Digitized by Google

Let A B (Fig. 2) represent a tunnel conveying a current. Let P Q R S be a small cube of the unstrained solid at some distance, say $a$, from the tunnel A B. Let $p\ q\ r\ s$ represent its form and position when the solid is sheared by the action of the current.

Draw $p\,r'$ & $q\,s'$ parallel to P R & Q S.

Then $rr'/pr' = \sigma$ represents the shear produced by the current A B at the distance $a$.

Now let there be another tunnel, conveying a fluid current, in the block. Examining all the positions it may have while a point of it is kept at a fixed distance from A B, we see that the stress in the intervening solid caused by the combination of the shears due to both currents is *least* when the currents are parallel and in the same direction. We see, further, that the *nearer* the parallel currents are to one another the less will be the average stress in the intervening solid, since the shears due to each more and more counteract one another. There will be a small displacement of the whole intervening solid in the direction of the currents.

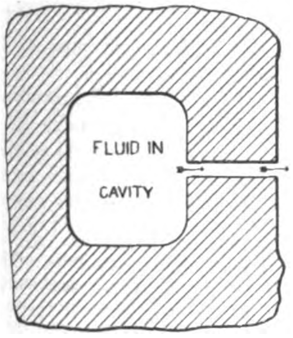

Fig. 1.

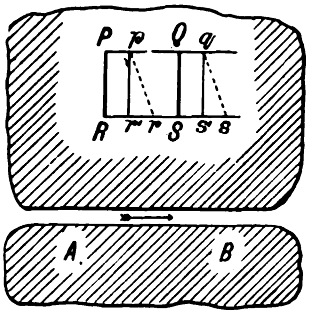

Fig. 2.

In this case, unless the currents be separated by an infinite distance, the average potential energy stored in unit volume of the solid is *less between the currents* than outside them.

But suppose the currents to be in one plane, parallel to one another, and contrary in direction. The farther apart they are the less will be the stress per unit volume in the intervening solid. But unless they be at an infinite distance apart it will always be greater than the stress outside. They will therefore repel one another.

Do not these cases seem to some extent analogous to the attraction and repulsion of electric currents? [Mentioned in (2) art. 40 of your "Modern Views of Electricity."]

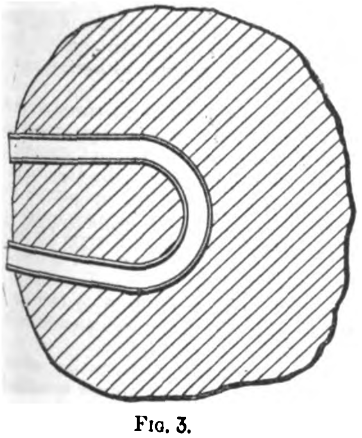

Fig. 3.

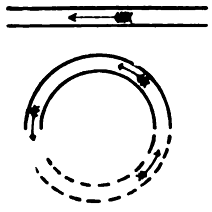

Fig. 4.

The difference is that the electric stress appears to be applied by a medium in which the conductor is free to move; while the current of liquid in the tunnel can get no farther than a mere ineffectual repulsion: unless it be actually true that a current flowing, say, in a thin indiarubber tube buried in cobbler's wax would really become circular in time. (Fig. 3).

You will see that the same principle of considering the form of current which produces minimum average stress in the solid provides an analogue for (3) article 40.

Also the starting, stopping, or varying of a current in one tunnel will certainly disturb the equilibrium of fluid in any other tunnel in the same block.

Take, also, the case of a current flowing in a tunnel shaped as a ring or helix. (Fig. 4). If there be another tunnel conveying a current, in the same block of solid, it will tend to turn so as to lie in the plane of the ring, or in a plane perpendicular to the axis of the helix. This, of course, corresponds to the action of a solenoid.

The mistake which you notice on page 166 as to the effect of a current of fluid on the form of a pipe seems rather to be due to an omission in the analogy.

Would not the following do?

| | |
|---|---|
| A tunnel in *a block of* elastic solid, conveying a fluid current, tends to become a circle; or, . . . is in the position of minimum potential energy when a circle. | A wire surrounded by dielectric, and conveying a current of electricity, tends to form a circle. |

The comparison of the cable and electric tramcars shows well the contrast of circumstances in which we are usually placed in comparing electric and mechanical phenomena. On page 96 of "Modern Views of Electricity" you have . . . "energy reaches the [cable] car viâ the rope and connector" (which transmit energy by static stress: not viâ the air which transmits energy by diffusion of motion with loss through heating). Again, "energy reaches the [electric] car . . . through the general insulating medium between cable and earth."

The only difference seems to be that the car in the one case is surrounded by fluid (a *conductor* of motion) and connected to the motive power by a rope of solid, which transmits the energy; in the other case the car is surrounded by dielectric (solid to *electricity*), and has only a rope of *conductor* (fluid to electricity).

I hope I have not annoyed you by writing so long a letter; my only excuse is that I am deeply interested in the subject, and I felt that it was a pity not to point out the amplification by which, I believe, your analogy between fluid and electric flow is made good. It had been my original intention merely to write a short note to tell you of it, but finding that the consideration of the flow of fluids in tunnels leads to the apparently useful results and analogies which I give above, I determined to include them. Hoping you will excuse the liberty I have taken, I remain

Your obedient servant,

Jas. Erskine-Murray.

Stud. Nat. Phil., Glasgow University.

## MR. RICHARD CHAMBERLAIN AND THE CHELSEA ELECTRICITY SUPPLY COMPANY.

**TO THE EDITOR OF THE ELECTRICIAN.**

Sir: On behalf of my Company may I ask you to kindly publish this letter in reply to Mr. Richard Chamberlain's very unfair attack upon the Company in the House of Commons on the 9th inst., an attack which Sir M. Hicks-Beach's reply showed was based by Mr. Chamberlain on complete ignorance of facts.

Mr. Chamberlain's question was whether the attention of the President of the Board of Trade had been "called to the long-continued default of the Chelsea Electric Supply Company to furnish the statutory current of 100 volts, and to the serious loss of illuminating power sustained by consumers in consequence," and he finished up his question by also asking whether the Board of Trade would take steps to compel the Company "to keep faith with the public or forfeit their concession."

Now, on behalf of my Company, I have to state specifically: 1. The Chelsea Company has not failed to keep faith with the public. 2. The pressure for this year has averaged over 100 volts (the statutory standard); but the regulations of the Board of Trade necessarily and specifically allow a variation of pressure of 4 per cent. above and below 100 volts, a variation, I may add, which of necessity takes place, and which is imperceptible to the consumer without the use of a delicate instrument. 3. There has never been a failure of light, and hardly any complaints (except from Mr. R. Chamberlain) have been received from customers, and these few have been remedied at once.

Why Mr. R. Chamberlain should use his position as a Member of Parliament to the detriment of a trading concern honestly doing its best, I am at a loss to understand; and if his remarks were made outside instead of inside the assembly to whom they were addressed, he would be brought to account for them. It is true my Company has not used Messrs. Chamberlain and Hookham's meter; but Mr. R. Chamberlain, I believe, possesses a "voltmeter," and, being a gentleman of leisure, studies this instrument with a view, if they fall below the statutory pressure, of pouncing upon the Company, he being ignorant of the standard. Whatever Mr. Richard Chamberlain's motives may be, my Board protests most emphatically against his attack (based upon an absolutely

Digitized by Google

erroneous view of the statutory rights and obligations) upon a Company which has not broken faith with the public, but which has, under great difficulties, successfully given a good and constant supply of electric light to a large and important district—a supply, I believe, more perfect than any other in the United Kingdom.—Yours, &c.,

J. IRVING COURTENAY, Chairman,
Chelsea Electricity Supply Company (Limited).
Draycott-place, Chelsea, S.W., December 10, 1890.

## THE TOMMASSI MULTITUBULAR ACCUMULATOR.

TO THE EDITOR OF THE ELECTRICIAN.

SIR,—My attention has been called to a note on the Tommasi secondary battery, which appeared on p. 130 of your last issue. This leads one to believe that this new battery is the invention of M. Donato Tommasi. This is not so. It is an exact description of Dr. Woodward's new battery, patent No. 6176, of 1890, a description of which I will supply you for publication at an early date, also a list of Dr. Woodward's many inventions taken out in connection with the electrical industry since 1874, which, I may say, include the first patent for an incandescent lamp, the sub-division of electricity, the multiple arc distribution of light, the modern storage battery, and numerous other inventions, many of which are worked and believed to be the inventions of others, probably without a knowledge of previous work actually done by Dr. Woodward. However, I believe in giving credit to those to whom credit is due.—Yours truly, ARTHUR SHIPPEY.

London, December 11, 1890.

# LEGAL INTELLIGENCE.

### Watt v. Maxim Electric Company—Maxim Electric Company v. Watt.

These two cases came before Mr. Justice Romer on Thursday last week. Mr. Rigby, Q.C., Mr. Sidney Woolf, Q.C., and Mr. G. F. Hart appeared for Mr. Watt; the Solicitor-General, Mr. Haldane, Q.C., and Mr. Marten for the Company. In the first action Mr. Watt claimed a large sum for salary due to him as managing-director, commission, rent of offices, money paid, and damages for wrongful dismissal from his office of managing-director, and for royalties on certain patents. In the second action, the Company claimed an account against Mr. Watt and damages on the ground of alleged improper dealing on his part, in taking commissions not really earned, for profits made by him on transactions in the shares of the Company, for neglecting to keep on foot certain patents, and for expenses of experimenting in connection with the patents which Mr. Watt now asserted to be his property.

Mr. WOOLF opened the plaintiff's case in the first action. He said the Company was originally known as the Electric Light and Power Generator Company, and some time in 1882 or 1883 Mr. Watt joined the Board. The Company was then in a low state, and by Mr. Watt's exertions it was put on a sound basis, and he altered its name to that of the Maxim Electric Company. In September, 1883, an agreement was entered into by which Mr. Watt became managing-director for three years, at a salary of £600 a year, and a commission of 5 per cent. on the net profits for each year. That agreement was acted on for three years, and on February 1, 1885, by endorsement, it was extended for another three years from Jan., 1886, but with this variation—that his salary was to be £1,000, £1 100, and £1,200, subject to six months' notice on either side. The plaintiff received his salary down to the end of 1886, and £1,000 for 1887, leaving £100 due to him, which formed the first head of claim. Then he claimed £70. 16s. 6d. commission on the profits for 1887. The plaintiff continued to act as managing-director to August 1, 1888, and the next claim was for seven months' salary, at the rate of £1,200 a-year. The next claim was for wrongful dismissal. The next item of claim was for money paid to clerks between August and October, 1888. The next claim was for a share of the Directors' fees, and the next for rent. An arrangement was made under which Mr. Watt's offices, 78, Queen Victoria-street, were to be used as the Company's offices, at a rent of £200, which was paid up to the end of 1887, and the books, &c., having been removed in June, 1888, plaintiff claimed six months' rent, and another nine months' in lieu of notice up to March, 1889, which would have been the earliest time when the Company could have properly determined the tenancy. The next claim was for royalties on certain patents for dynamos and lamps, in respect of which the defendant Company claimed to charge plaintiff for wages, and materials expended thereon in experimenting. Lastly, he claimed damages for the non-registration of transfers of shares executed by him, and that was now limited to 5,416 shares, though originally the number was put at 7,376.

The SOLICITOR-GENERAL opened the case for the Company, as above summarised.

Mr. HUGH WATT, M.P., was then called by Mr. WOOLF, and gave evidence in support of his own case.

The hearing was then adjourned.

FRIDAY, DECEMBER 5TH.

On the resumed hearing of this case Mr. HUGH WATT continued his evidence in support of the various claims he set up.

The item first dealt with was the royalties claimed by Mr. Watt on patents for the Watt dynamo and arc lamp, and the cross-claim by the Company for the expenses of experimenting with these patents. The minutes of the Board were referred to, authorising an arrangement for working the patents. Without using the patents the Company could not have carried on its operations. The patent for the dynamo was in his name, and he undertook to defray all charges in connection with it; the other patent was in Mr. Lee's name, and he had an assignment of it in August, 1888, but had arranged to purchase it previously. The Company could not find the money to purchase the patents, and he agreed to accept a royalty instead. The Company had all the machines and lamps which were manufactured under these patents to the value of £1,500. As settled by himself and the works manager, they had sold all their assets to a new company. He never concealed from the Company that he was the owner of these patents. He told the Board of his negotiations with Mr. Farquharson, the inventor of the dynamo, and that he would buy it and let the Company have the benefit. He did not recollect when he sent in his claim for the royalties, but he explained the whole circumstances to a general meeting.

The next item gone into was the claim for damages for non-registration, and the counter-claim by the Company for 5s. a share on 2,710 shares.

Mr. Watt was then examined as to the claim by the Company for excess commission overpaid in the years 1884 and 1885. The balance-sheet for 1884 was put in. It was submitted to the shareholders' meeting on February 18, 1885, and adopted. He believed it showed the true state of affairs, and his commission was paid accordingly, viz., £248. 15s. 6d., after the general meeting. On February 8, 1886, a Board meeting was held, when the accounts for 1885 were adopted and ordered to be circulated. There was a letter from the auditor accompanying his certificate, in which he said the balance-sheet was of an exceptional character. There was a general meeting on February 19th, when the balance-sheet was presented. The report and accounts were adopted. The profit shown for that year was £5,284, on which he received his commission, after deducting the balance brought forward of £2,430 and adding £3,606. 5s., which was carried to a reserve fund, being premiums on new shares. He received his cheque for £323 commission on February 2nd.

The SOLICITOR-GENERAL pointed out that this was before the balance-sheet had been adopted.

His LORDSHIP said the plaintiff was clearly liable to refund 5 per cent. on £3,606.

Mr. WATT, continuing, said he considered he had a right to treat the book debts appearing in the balance-sheets for 1884 and 1885 as good; the articles sent abroad were invoiced at prices fixed by the Board. In some cases the arrangement was that they should be paid for in six months; in others they were to be paid for when sold. The Company had a large stock, and the Board desired to realise it. The goods sent to the Mauritius he considered were sold out and out; the others were merely consignments. Including these accounts did not increase his commission; they would otherwise have appeared as stock, and the result on profit and loss would have been the same. With regard to the alleged profit made on the sale of shares in the Company, there was no truth in the allegation. With regard to allowing the patents to lapse, it was the duty of the secretary to see to those matters on the report of the patent agent. Those which lapsed were useless; they were all early patents, with one exception, which expired after he left the Company.

Mr. WATT was then cross-examined by the Solicitor-General as to the number of companies whose offices were at 32, Queen Victoria-street, as to the clerks employed by him on behalf of the Maxim-Weston Company, and as to the appointment of Mr. Howell as Director. Mr. Dever, in his letter of March 21, 1888, drew attention to the fact that the patents stood at a much higher figure than in the previous year, the increase being made up by transfers from the working expenses account of charges for experiments on the Watt dynamo and arc lamp. Witness at first denied that this was the case, but on being pressed admitted it. One item was £750, proportion of managing-director's salary; that was held to increase the value of the patents by that amount, and so to bring out a profit balance on which he was entitled to commission.

The remainder of the afternoon was occupied with questions as to the goods sent abroad on sale, the invoice prices of which were brought into the profit and loss account, and commission charged accordingly. Mr. Watt said he believed the accounts would have stood exactly the same if these goods had not been sent out.

The case was then adjourned.

SATURDAY, DECEMBER 6TH.

On Saturday Mr. WATT again took his place in the witness box for further cross-examination by the Solicitor-General.

Mr. WOOLF said he had had an opportunity of consulting his leader, Mr. Rigby, and he did not propose to contend further that Mr. Watt was entitled to commission on the £3,600 which was brought into the balance-sheet for 1885, and reckoned as profit, though it consisted mainly of premiums on shares. He also gave up the claim for nine months' rent of offices in lieu of notice, and to £70. 17s. 6d. commission on the profits for 1887, the balance-sheet for that year not having been duly certified, as it was evident now that Mr. Howell was not properly appointed a Director.

The SOLICITOR-GENERAL then continued his cross-examination with regard to the goods sent abroad, the invoice prices of which were brought into the account as cash; but after a few questions Mr. Watt said he had looked into the books and was willing to concede £100 on that head (the total amount claimed by the Company being £137), and the Solicitor-General said he would accept that rather than incur the expense of a minute inquiry into the exact figures. He then went into

Digitized by Google

the claim of £100 balance of salary for 1887. The Solicitor-General read out a list of twelve cheques to Mr. Watt during 1887, one in each month, of £100 each, and they were all entered in the books as for salary. Mr. Watt examined the cheques and admitted they were correct. The Solicitor-General pointed out that, instead of Mr. Watt being entitled to £100 more, he had been overpaid £100. The Solicitor-General next dealt with the claim for salary for the year 1888. Being an annual engagement, he thought he might contend that nothing was due for an uncompleted year.

After a little discussion, Mr. Woolf gave up the claim to the seventh month, the claim being admitted to the extent of £600, or six months.

The SOLICITOR-GENERAL said the next point he wished to establish was that no profits whatever were made from 1883 to 1888, and that none of the £323 paid to Mr. Watt as commission on profit ought to have been paid; £18C had already been struck off, and he would now show that the balance must also go.

One item put was Ralli Brothers, £42. 10s., for goods supplied in July, 1884, for which a cheque for £8. 11s. was accepted in settlement in October, 1884, but the full amount appeared in the accounts for 1885. Mr. Watt said he did not recollect the particulars of this case. Several other cases of a similar character were put, and the same answer given. The estimate of bad debts for 1885 in the report was £600, but it was not deducted in the balance-sheet. He admitted he was not entitled to commission on that £600, and that that allowance afterwards turned out to have been insufficient. In 1883, 1884, 1885, and 1886 he assisted Mr. Tough, the works manager, in valuing the stock. The value was held up at the original cost. Dynamos did not deteriorate by standing; they might get obsolete. He stated the facts to the shareholders at each general meeting; they followed the practice of their predecessors in this respect. In the year 1886 he directed those who prepared the balance-sheet to put up the price of some things in the stock-sheet, which had been at a lower price the previous year. Some dynamos had been unwound, and were afterwards rewound. He did not direct a Pooley's weighing machine, which had been previously valued at £5, to be put at £10. 10s. He should take the value of all such matters from Mr. Tough. The same answer applied to five vices taken in 1885 at £10, then increased to £13. The same with regard to a drilling-machine increased from £12 to £30, and subsequently in 1887 reduced again to £12. He knew nothing about the value of these things. He certainly did not suggest the over-valuing of stock in order to increase the apparent profit. The other Directors had a contingent interest in the profits, having a commission over 6 per cent. Several other items of a similar character were put. If he had noticed any such remarkable cases of increased value in the same machines he should have asked for some explanation from the works manager. A list of articles alleged to have been over-valued in this way was put in, and also the stock lists for 1835 and 1856, signed by Mr. Watt and the works manager. These books, when signed, were put before the auditors. Rough books or sheets were prepared beforehand. The rough book for 1887 was next shown to the witness, who was asked why the amounts therein were altered in pencil. He said they were not altered by him. Asked to read one of the alterations, he read, "One clock, superior, £2;" altered to £3. 10s. He thought that was in the writing of Mr. Wright, the secretary. Another entry to which his attention was called was "25cwt. steel, £20;" altered, in pencil, to 75cwt., £55; and then, again, altered to £60. The last figure was not his writing. He saw no figures in the book in his writing. He should make no alteration from interested motives. The only interest of anyone connected with the Company was to have the figures correct. He knew nothing about an atmospheric engine, put down first at £50, then altered in pencil to £100. It was not an engine which he referred to in a letter as having had at his own house, and ordered to be taken away as it was no good; that was a gas engine.

The SOLICITOR-GENERAL said his clients did not possess the signed stock sheet for 1887, but from the balance-sheet for that year it was evident that the signed list put before the auditors was made from the rough list now put in, and according to the increased figures.

Cross-examination continued: Electrical patents were constantly diminishing in value. From 1883 to 1887 the only reduction in the value was in 1885, when they were reduced one-half, and they were afterwards put up to about £40,000. They were entitled to any improvements made by the Maxim-Weston patentees. He did not know what the value of those American improvements would be. There was never any real valuation of the patents—he did not see how it could have been done; no depreciation was written off them. The auditor drew attention to the matter, but when it was brought before the shareholders they took the opposite view, and objected to reducing the value. The Solicitor-General said that on February 6, 1885, there was a meeting of the Directors, when the report and balance-sheet were ordered to be printed. Mr. Dever's letter was also read, in which he drew attention to the fact of the patents being held up at the previous valuation, and said he had the assurance of the chairman that that was justified. The general meeting was held on February 18th, and no notice appeared in the report of the meeting of Mr. Dever's letter being read. The Solicitor-General read an extract from Mr. Watt's speech at this meeting, in which he said that the new patents acquired by the Company within the previous 20 or 21 months were intrinsically worth the whole amount charged against the patents account, independent of all the others, and the improvements of the American Company to which they would be entitled up to 1887. At that time the patents stood at £70,000, but at the end of the year they were suddenly reduced to £35,0C0.

Mr. WATT, in answer to questions, said he could not remember what the new patents were to which he referred. Several patents were allowed to lapse, and by March, 1888, only three remained out of 14, besides the Watt dynamo and arc lamp patents. The Board decided in each case, as to allowing the patents to lapse, after consultation with the works manager. These things ought to be recorded in the minutes, but they might not always have been entered. Patents were allowed to lapse from 1883 onwards. Those which were abandoned were of no value. The three patents which remained were the principal ones on which the Company worked. He considered that the Company had made profits. Two dividends were paid. When he left the Company there was a very small cash balance; there were £10,000 outstanding accounts which could not be collected, owing to the disputes. The three patents remaining were not separately valued. They were judged of commercially, according to the amount of business they enabled the Company to do.

A considerable time was spent in endeavouring to obtain from Mr. Watt an explanation of the manner in which the value of the patents was arrived at, but without much light being thrown upon the question. Ultimately, in answer to his Lordship, he said that at the time he left the Company the three remaining patents were practically valueless, the only ones of importance being the Watt dynamo and arc lamp patents, which he acquired in order to enable the Company to compete with other manufacturers.

The case was then adjourned.

MONDAY, DECEMBER 8TH.

On the resumption of the case on Monday, the Solicitor-General gave a summary of the claims he still had against Mr. Watt.

After some discussion, Mr. Justice ROMER suggested that it might save a deal of time and trouble if, without going through all the items one by one, some general settlement could be arrived at between the parties. If there were a likelihood of this being done, he would rise for a short time to allow the parties to consider it.

Counsel on both sides expressed the hope that a settlement might be arrived at, and thanked his lordship for the suggestion. The Solicitor-General added that, as he appeared for official liquidators, he could only accept a settlement which received the sanction of the Court.

Mr. Justice Romer then left the Court.

The parties having consulted for about an hour, his lordship returned into Court.

Mr. RIGBY stated that a settlement had been arrived at. The settlement was to include all questions as between the Company and Mr. Watt, whether properly raised in this action or not. Mr. Watt would pay the liquidators a certain sum standing to his credit in respect of shares purchased by the liquidators. That sum, which had been put down at £330 14s., was standing to the joint account. The other money standing to the joint account would also be paid to the Company. Mr. Watt would, in addition, pay a sum of £669 6s. to make up, with the previous sum, £1,000. Then, as the actions had got so mixed up together, he had agreed, though there might have been some argument raised about it, to pay the taxed costs as between party and party of both actions. Further, it had been concluded, in order to make a settlement of all matters, that Mr. Watt should not pay any costs in reference to the winding-up petition, but in the costs proper of both actions those of the motion to rectify the register would be included.

The SOLICITOR-GENERAL, on behalf of the Company, merely added that the liquidators were anxious, as he had stated previously, to obtain his Lordship's approval of any terms at which they might arrive. He trusted the Court would consider, having regard to what had taken place, that the settlement stated was a proper one.

His LORDSHIP said he thought so, and that the parties had acted very wisely in the matter.

## SMITHFIELD CLUB SHOW.

The ninety-third annual show of the Smithfield Club has been held during the current week, and closes this day (Friday). The exhibitors include a number of well-known engineering firms, amongst whom may be mentioned Messrs. W. Allchin, the Atlas Engine Company, Brown and May, C. Burrell and Sons, Clayton and Shuttleworth, W. Foster and Co., John Fowler and Co., Garrett and Sons, Gibbons and Robinson, E. S. Hindley, Richard Hornsby and Sons, E. Humphreys, Marshall, Sons, and Co., Priestman Brothers, Ransomes, Sims, and Jefferies, Robey and Co., Ruston and Proctor, W. Tasker and Sons, E. R. and J. Turner, Wallace and Stevens, Weyman and Co., Woods and Co., Barford and Perkins, Blackstone and Co., and A. Dodman. A large display of machine belting was also shown, the principal stands being those of Messrs. Willcox and Co., W. W. Cobbett, J. Dawson and Son, the Gandy Belting Manufacturing Company, D. B. Hooke, Rands and Jeckel, J. Walker and Co., W. Eddington, T. H. Haagen, Son and Co., S. E. Norris and Co., Sheaf Brothers, and G. Thurlow.

Messrs. MARSHALL, SONS, and Co. are represented by a 10 horse-power nominal compound stationary steam-engine, erected underneath a locomotive multitubular boiler, fitted with Hartnell's patent automatic expansion gear, automatic sight-feed lubricator, and a steam-trap for draining the cylinder jackets, the engines being specially adapted for electric lighting purposes. This firm also show a 7 horse-power nominal portable engine, mounted on wrought iron travelling wheels with shafts; a 6 horse-power traction engine of great strength, with two speeds of crucible cast steel driving gear arranged inside the frame. The chief features of interest to our readers in Messrs. Marshall's exhibits are:—(1) A new pattern class "M" independent vertical engine cylinder, 6¼" × 10", fitted with Moore's crankshaft governor and automatic cut-off balanced slide valve, and a patent automatic sight-feed lubricator,

Digitized by Google

&c. This engine is specially adapted for electric lighting, ample provision being made for thorough lubrication, and the governor controls the engine, so that there is practically no variation in the speed with a shifting load. (2) A self-contained engine of the horizontal type, with cylinder 10″×14″. This engine has a force pump added; and Messrs. Marshall claim for it that it will be found a perfect engine for electric lighting or other machinery requiring very steady running.

Messrs. ROBEY and Co.'s exhibit includes a Compound "Robey" Engine and Locomotive Boiler combined, largely used for electric light installations, and for driving machinery where perfectly steady running is necessary, for which work it is specially adapted. This engine is extremely economical in fuel, consuming under 2lb. of best Welsh coal per indicated horse-power per hour. A High-speed Vertical engine is also shown, which has been specially designed for driving electric light machines on board ship, in flour mills, and where great power is required in a small space. It works with a high steam pressure, and may be arranged to run at various speeds. It is self-lubricating. When used for electric lighting it is mounted on a cast iron bed-plate, the other end of which carries the dynamo. The base-plate is provided with lugs and adjusting screws, so that the driving belt can be tightened without stopping the machinery, and forms a strong, durable, and compact motor. Messrs. Robey also show a long-stroke horizontal fixed engine, and several of their well-known portable and vertical engines.

As is usual at these shows, the electric light was conspicuous by its absence.

## TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning.*]

PRIMARY BATTERY INSTALLATION FOR SALE.—Our advertisement columns contain a notice of a sale by tender of a complete electric primary battery installation, comprising battery cables, volt and ampere meters, switches, and 36 hanging lamps with shades and holders. For further particulars application should be made to Messrs. C. Wallington and Co., Chartered Accountants, 4, Tokenhouse-buildings, London, E.C., to whom tenders are to be sent on or before Thursday, December, 18, 1890, at 3 o'clock.

TENDERS RECEIVED.—The request for tenders for installing the electric light at the Mullingar District Lunatic Asylum, Co. Westmeath, resulted in the following being sent in:—Siemens Bros. and Co., London, £3,713; Latimer Clark, Muirhead, and Co., London, £3,067; Rashleigh, Phipps, and Dawson, London, £3,064; W. T. Goolden and Co., London, £2,904; Edmundson, Dublin, £2,805; Fowler, Lancaster, and Co., Limited, Birmingham, £2,400; Crompton, Limited, Chelmsford, £2,310; Mather and Platt, Manchester, £2,310; Sharp and Kent, London, £2,277; Drake and Gorham, London, £2,261; B. Verity and Sons, London, £2,259; Manchester Edison-Swan Co., Limited, £2,205; Electric Engineering Co. of Ireland, £2,090; Gülcher Electric Light Co., Limited, London, £2,045; J. D. F. Andrews and Co., London, £1,950; J. E. H. Gordon, London, £1,850; Woodhouse and Rawson United, Limited, London, £1,790; Electric Engineering Corporation, West Drayton, £1,755.

BRISTÖL'S PORTABLE LAMPS.—Mr. Bristöl was recently awarded the diploma and gold medal at the International Exhibition of Mining and Metallurgy held at the Crystal Palace. This was, we are informed, the highest and only award given for electric safety lamps at the exhibition.

MR. JAMES JOHNSTONE.—Mr. James Johnstone, iron and metal agent, 51, St. Vincent-street, Glasgow, has been appointed agent for the Northern Electric Wire and Cable Manufacturing Company, Halifax, and for Messrs. V. George-Frère, Charleroi, Belgium.

THE LIGHTING OF THE GLOBE THEATRE.—In our note of last week we incorrectly stated that the contract for lighting the Globe Theatre had been given to Messrs. Dickenson and Co. The firm who have secured the contract are Messrs. C. E. Gilbert and Co., of 16, Hanway-street, Oxford-street, W.

MESSRS. GIRDLESTONE, TATHAM, AND CO. The members of the cricket and football club in connection with this firm held a smoking concert on Friday evening last, December 5th, at the Horse Shoe Hotel, Tottenham Court-road. The chair was occupied by Mr. Tatham, and there was a good attendance of the members and their friends.

MESSRS. A. AND E. ROBINSON.—We have received from this firm illustrated price lists and particulars of their patent air engine. Accompanying the price lists are testimonials from users of the engine, for which Messrs. Robinson claim several advantages, and more particularly its usefulness where room and attention are not available.

## PATENT RECORD.

### APPLICATIONS FOR PATENTS.

**NOTE.—*The undermentioned applications are not open to public inspection until after the acceptance of the complete specification. The names within parentheses are those of communicators of inventions.***

November 27, 1890.

19,308. J. S. SWINBURNE. Teddington. Improvements in and connected with electrical distribution of power by alternating currents, and their measurement.

19,315. H. NUNNS. London. Improvements in electric arc lamps.

19,344. E. PLACET and J. BONNET. London. Improvements in electrolysis in general, and particularly in electrolysis of metals.

19,345. A. J. BOULT. London. Improvements in suspension devices for incandescent lamps. (H. Rentzsch, Germany.)

19,355. S. BACON. London. An improved electrical connection or plug.

November 28, 1890.

19,406. E. HARTMANN and W. BRAUN. London. Improvements in electric current meters.

19,418. G. HANNAH. London. Improvement in electrical tell-tales for twin-screw steamers.

19,423. E. A. DUCRETET. London. Improvements n apparatus for the electrolytic production of gases.

November 29, 1890.

19,467. J. P. BAYLY. London. Improved electric arc lamp. (A. Wagnière, U.S.A.)

19,485. H. E. G. EARLE. Southampton. Automatic railway signalling by electricity.

19,486. A. R. BENNETT. Manchester. Improvements in telephonic switching apparatus.

19,496. J. F. MUNSIE. London. Improvements in insulators.

19,505. A. WYLIE. London. Improvements in the method of, and in the machinery for the manufacture of lead or metallic boxes and plates for electric accumulators, and other kinds of lead or metallic boxes, plates, tubes, rods, and strips of irregular section, or plain, ribbed, corrugated, and fluted by hydraulic pressure.

December 1, 1890.'

19,509. W. H. PIKE. London. Electric sewing needles, knitting needles, pins, pens, and the like.

19,555. F. A. OETZMANN. London. A portable room for telephone.

### SPECIFICATIONS PUBLISHED.

1889.

18,361. DE FERRANTI. Electric meters. (Price 6d.)

19,285. CAMPBELL. Ships' electrical signalling apparatus. (Price 8d.)

20,645. DEARLOVE. Telegraph cables. (Price 4d.)

20,955. WOOD. Dynamo electric machines. (Price 1s. 5d.)

1890.

16,124. FAIRGRIEVE. Electric clocks. (Price 8d.)

16,322. CURRIE. Electric batteries. (Price 8d.)

16,324. LLOYD. Battery plates. (Price 8d.)

## COMPANIES' MEETINGS & REPORTS.

### Montevidean and Brazilian Telegraph Company (Limited).

An extraordinary general meeting of this Company was held at the offices, Langthorn House, Copthall-avenue, on the 10th inst., Dr. Cameron, M.P., presiding, when the subjoined resolutions, which were passed at the extraordinary general meeting of the Company, held on the 25th ult., were submitted for confirmation as special resolutions.

1. *That the Company be wound up voluntarily under the provisions of the Companies' Acts.*

2. *That George Fraser, F.C.A., be and he is hereby appointed the liquidator to conduct such winding up.*

3. *That the agreement submitted to this meeting, dated November 3, 1890, and expressed to be made between this Company, of the one part, and the Western and Brazilian Telegraph Company (Limited), of the other part (being an agreement for the sale and transfer to the Western Company of the whole of this Company's undertaking), be and the same is hereby approved. And that the liquidator be and he is hereby authorised, in pursuance of Section 161 of the Companies' Act, 1862, and of all other powers enabling him in that behalf to carry said agreement into effect with such modifications (if any) as he may think expedient.*

4. *That the liquidator be and he is hereby authorised to receive, and when received to distribute amongst the holders of Preferred shares in this Company the rent accruing to this Company from the Western and*

Digitized by Google

*Brazilian Telegraph Company (Limited) for the year ending December 31, 1890.*

5. *That the shares in the Western and Brazilian Telegraph Company Limited), to be received as the consideration for the sale and transfer to them of this Company's undertaking, shall be appropriated as follows:—*

*To the shareholders in this Company in exchange for their shares at the rate of one share in the Western and Brazilian Telegraph Company (Limited) for each two shares in this Company.*

*To the holders of Debentures of this Company in exchange for such Debentures at the rate of ten shares for each £100 of Debentures.*

*To the liquidator in satisfaction of his remuneration, and to the Directors and officers of this Company, as compensation for the loss of their offices, 155 shares.*

*The remaining shares to be sold, and the proceeds after payment thereout of the expenses of the liquidation, other than the liquidator remuneration, to be distributed amongst the shareholders in this Company pro rata, according to the number of shares held by them respectively.*

The SECRETARY (Mr. James Fraser) read the notice convening the meeting.

The CHAIRMAN said that the only business was the confirmation of the resolutions passed at the late meeting.

Mr. POTTER (the only shareholder, as such, who attended the present meeting) was at the former meeting, of which the shareholders had been furnished with a full report. He had nothing to add to what he then said, except that they had received as emphatic approval, in the shape of proxies, for the confirmatory meeting as they received for the recent meeting. They had, on the present occasion, received proxies for 7,613 shares. He concluded by proposing the confirmation of the resolutions.

Colonel MACAULEY seconded the motion, expressing the opinion that the shareholders had got very well out of the affair. The property was depreciating every day.

The CHAIRMAN put the motion, and it was unanimously agreed to.

Mr. POTTER proposed a vote of thanks to the Chairman, adding that he thoroughly appreciated what had been done by the Directors, as, no doubt, did the other shareholders.

Mr. CRISP (the solicitor) seconded the motion. If Dr. Cameron had not come into the concern when he did, and taken the helm of affairs, he was sure that the whole thing would have gone to pieces.

The CHAIRMAN, in reply, said that since he had been in the Company he had had the most cordial relations with the shareholders.

The meeting then separated.

## The Fowler-Waring Cables Company (Limited).

The second ordinary general meeting of the Fowler-Waring Cables Company (Limited) was held at Winchester House, Old Broad-street, London, on Friday, December 5, 1890, under the presidency of William Fowler, Esq.

The SECRETARY (Mr. George Neill) having read the notice convening the meeting,

The CHAIRMAN said: Gentlemen, I have to move "that the report and accounts, as delivered to the shareholders, be received and adopted." When I met you here almost to a day a year ago, I certainly anticipated that we should have made rather further progress than we have during that time. We have had, as stated in the report, unexpected delays, and the consequence has been that we have not been as far forward as we expected to have been a year ago; but I am glad to tell you that we have now obtained that which we always intended to have, namely, a factory in most excellent order, and ready to do a very large and, I think, hope, and believe, a very profitable business in the future. You will all agree with me, I am sure, that these delays are almost a matter of course in all industrial undertakings. They certainly have been greater than we expected; but it is of no use troubling ourselves about that if we are now in the position we desired to be in: and in reference to that there is one very important observation that is, the question of management. Now, for some months past we have had a manager who, I believe, will prove to be—as I think he has proved to be—a most excellent manager. I do not think I ever met a man who impressed me more favourably in his position, and I am thoroughly satisfied that we have now got the management we wished to have; and that, I need hardly say, is the most important question we have to consider. If we have good management, I do not think there is the smallest doubt that we shall have a profitable business; but if we have not good management, no business of this kind—or, in fact, of any kind—can be profitable. I wish also, with reference to that, to say that the manager is not merely a man who goes down from London and looks at the place, and comes back again, but he resides in the factory, and is therefore able to maintain a continual supervision, which is of the utmost importance, as I think you will all agree. Now I should very much like for any shareholder who feels any doubt about the present position of the Company to go down and make an arrangement with Mr. Mavor to look over the place. I think he will then agree with me in the feeling which I had when I was last there—a few days ago—that the position of the factory is a remarkable one—not only the position as regards the place where it is, but the excellence of the supervision and the most superior quality of the work. If anyone desires to see what the work is, an inspection of the samples made at the factory which are at the offices of the Company at 85, Queen-street, Cheapside, would satisfy anyone with the slightest knowledge of the subject that the work done is of the most excellent character. Now, the report states so clearly—combining the Directors' report and the manager's report—the exact position of the business that it is not necessary for me to enter into details. I have stated generally that we regret the delays, and we regret that we have not been able to pay you a dividend in the first year of our existence. We ought not, perhaps, ever to have expected to do so; but we had hoped we should. I have one observation to make, which is somewhat of a personal character, namely, that as we have not made any profit for you, we have taken no fees ourselves. We have, however, had very hard work, I can tell you, and a great deal to do and think about; but we have taken nothing for our work, considering that we have not made a profit for you. I wish also to make another personal observation. Leaving myself entirely out of the question, and regarding myself as a person not to be mentioned, I do not think you could find a more intelligent or diligent Board in the whole of London. I should also like to say one other word of a personal character, and that is, that I feel we are all very much indebted to Mr. Eddison for the hard personal labour which he imported into the business at a very critical period, before we obtained the manager we now have. Gentlemen, I do not think I can add anything more to what I have said which would be of interest to you. The business is a very important one, and I hope and believe, though I am a man very jealous of making promises or of expressing confident anticipations (because I know the uncertainty in all business, from long experience), I do believe that this will be a most important, and, in the end, very profitable business. I think it is a business of great interest. It is a very singular and curious business, you may say, but I think it is a business which has in it the elements of a great success, and certainly it is one which is of a very interesting character. I do not think there is anything more I can add, and I can only say that if any gentleman wishes me to give him any further particulars beyond what I have furnished, or which are not mentioned in the report, I shall be very happy to give them to the best of my ability. I now beg to propose the motion which I have submitted already.

The Hon. J. S. GATHORNE-HARDY, M.P.: I beg to second that.

The CHAIRMAN: If no gentleman has any question to ask on the motion I have put to you, you have heard it, and those who are in favour of it will please to signify the same in the usual manner. On the contrary. That is carried unanimously.

On the motion of Mr. E. J. VAUGHAN, seconded by Sir HENRY EDWARDS, the auditors, Messrs. Cooper Brothers and Co. were reappointed.

The CHAIRMAN stated, in answer to Sir Henry Edwards, who thought the auditors' remuneration too large (50 guineas), that the matter should be considered. The Chairman afterwards observed that some of his colleagues thought he ought to say that while they most cheerfully waived their fees on the present occasion, the shareholders might be inclined—supposing, as he hoped, the Company had a "rattling good year" next year—to award the Directors some remuneration for the past as well as for the current year. This, however, was a matter entirely in the hands of another meeting.

Mr. VAUGHAN intimated that at a future meeting he would feel it his duty to suggest for the consideration of the Board whether so many as seven Directors were required, seeing that they had an experienced manager.

The CHAIRMAN replied that the remuneration of the Directors was settled by the Articles of Association, and the shareholders could not alter it unless the Directors chose to waive it, or part of it. He did not think, therefore, that reducing the number of the Directors would reduce their remuneration, and, as far as he was concerned, as Chairman of the Company, he did not know which of the Directors he desired to get rid of. This question, however, was not before them now, the business of the day being concluded.

Mr. VAUGHAN said he thought they had a most capable Board, and it would be a very invidious task for him, or any one, to select any member of it whom they could dispense with. He hoped, however, that the Directors would consider his suggestion, and would not ask for the re-election of absolutely every member of the Board.

The CHAIRMAN observed that there might be legal difficulties about the point; but he thought, from the way in which the Board had acted that day, that the shareholders might rely on the Directors dealing with the question in a liberal spirit.

Mr. WELLBORE ELLIS proposed a vote of thanks to the Directors for the way in which they had managed the Company's business, and to Mr. Eddison for his services. He thought they ought not to say that they required fewer Directors, for he felt sure that all these gentlemen would more or less bring the Company business.

Mr. SMART seconded the motion, which was carried unanimously.

The CHAIRMAN, in acknowledging the vote, assured them that the one desire of the Directors was to make the Company, not only a success, but a great success, and he believed they would do so.

The proceedings then terminated.

## Electric Construction Corporation (Limited).

The first ordinary general meeting of this Corporation was held on the 8th inst., at Worcester House, Walbrook, under the presidency of Sir Henry C. Mance.

The SECRETARY (Mr. F. Walton) read the notice convening the meeting, and the auditors' report, dated November 24th, as follows:—

"To the Members of the Electric Construction Corporation (Limited).

"Gentlemen,—We have audited the accounts from the commencement of the Company, viz., June 7, 1889, up to September 30, 1890, and have examined the profit and loss account and balance-sheet with the books, vouchers, and accounts.

"The sum of £121,963. 12s. 5d. on the credit side of the profit and loss account is represented to a great extent by shares which stand in the balance-sheet at par. It is impossible to say what is the exact amount that ought to be carried to capital account in respect of the cost of patents sold and depreciation caused by the licences granted, but we think the round sum of £100,000 should be ample. In connection with these financial transactions there is a contingent liability for uncalled capital, about

Digitized by Google

£90,000, but any payment in respect of this liability should increase the assets of the Corporation.

"We are informed by the managers of the works at Wolverhampton and Millwall that the plant and machinery have been fully kept up out of revenue, but we think it advisable that a considerable sum should be placed as a reserve for depreciation, and beg to suggest that the Directors' recommendation of placing £15,000 as such reserve should be adopted.

"One of the subsidiary sets of books do not balance by the sum of £1. 18s. 5d., and so much time has been occupied in endeavouring to find this difference that the completion of the audit has been delayed.

"We believe sufficient reserves have been made to meet any error affecting profit and loss account.—Yours faithfully,

"(Signed) BROADS, PATERSON AND CO."

The CHAIRMAN: Gentlemen, I have now the pleasure of presenting to you the reports and accounts of the Company for the period ending September 30th this year, and I presume that in accordance with the usual custom you will prefer to take them as read. That being the case, I will proceed without further delay to go through the accounts, and just touch on a few of the items that seem to me to require a little extra explanation. Now, commencing at once on the credit side of the profit and loss account, the first item is £4,061, on account of the apportionment of profit. I may explain that this represents the amount which, after liberal deductions for depreciation, cost of experiments, &c., the auditors certify as profit not belonging to capital. Although we took over the benefits of the working of the Elwell-Parker Company from September, 1888, we are not allowed to count towards revenue any profits that we made before the date of the incorporation of this Company. These profits go, therefore, to increase the capital value, and do not appear in our profit and loss account. There is some little difficulty in apportioning the exact amount of the earnings for the period mentioned; but you may take it that it is roughly approximate. Probably it has been put too low, but you will understand that if you have not these earnings set out as profits, you have them in the increased value of the business which we acquired. It is simply a matter of account. The items work, sales, and expenses speak for themselves, and I have only this remark to offer—that in considering the net trading profits it would be fair to include a considerable portion of the item that follows of £14,000 charged against head office expenses. This should be deducted to arrive at the net trade results. I may also point out that the head office expenses are for a period of nearly sixteen months, not twelve months. In connection with the item of interest on temporary loans, it is desirable to mention that in order to complete our engagements with the vendor, it was necessary to obtain temporary advances from the bankers. A part of this item might, therefore, fairly have been charged to capital; we think, however, that it is of more importance to put the affairs of the Corporation on a sound financial basis than to present to you too glowing a balance-sheet, and the same principle has been applied here as in the item of preliminary expenses and the "other expenses" item—that is to say, the whole of the expenditure has been written off against the first year's working. Further, with respect to that item of "other expenses," you will, of course, easily understand that advertising must always be a serious cost, as, if it is worth doing at all, it ought to be done well. A considerable portion of that sum, £3,918, is made up by the estimated cost of goods which were sent to the Edinburgh Exhibition, which, practically, is another form of advertisement. In pursuance of our policy to be on the safe side if possible, and bearing in mind the fact that returned goods are often very much depreciated in value, we have written off the entire cost of these goods, and if anything is realised eventually from them, it will come into the accounts as net profits. Then we have cash and shares—£121,900. When the Corporation took over the businesses that we have acquired, there were foreign patents of undoubted but undeveloped value. The patent fees themselves were a heavy charge, while the income was nominal. These patent fees, I may mention, are included under the heading of head office expenses. The Directors have made it their business to realise these foreign patents by handing them over to a subsidiary company. To a great extent this item is represented by paper only, that is to say, so far as the purchase-money for patents is concerned, they having been paid for in shares. The result of the transfer has fairly justified the expectations of the Directors, for not only has a drain upon revenue been stayed, but the transfer of these foreign patents has resulted already in a most satisfactory development of business in the countries concerned. Upon paper these transactions show an extremely satisfactory profit, but the shareholders will, I am sure, support the policy of the Directors in their decision not to apply any profits of the sales of patents to the credit of revenue until the present patent account has been practically written off. While on the subject of patents, I may mention that both at Millwall and Wolverhampton we are always experimenting in order to keep up with the business of the day, and it sometimes happens that in working on one thing we discover others which are even of more value than the object originally sought for. When we took over the Elwell-Parker business one of the patents which, I may say, was lying dormant at the time, was a method of obtaining phosphorus by the assistance of electricity from phosphate of aluminium. I regret that the gale of wind which we had in November damaged our buildings there, and therefore the experiment is not sufficiently advanced to allow me to say anything certain to-day, but Mr. Parker and his co-inventor, Dr. Reedman, are very sanguine—as inventors usually are—and they have every hope of bringing it to a successful issue. You may remember that the aluminium business has been completely revolutionized by the application of electricity, and I see no reason why we should not be equally successful with the phosphorus. Be that as it may, we risk very little, and I am sure we shall gain most valuable experience by our electrical furnace, from which I believe that great applications of electricity will be made in the future. With this little digression, we will go on with the balance-sheet, which I hope you will consider is a very good one, remembering that it is for the first year that we have had to get custom together, and that we have not had the benefit of our new works. I do not think that there is much for comment, but I should have liked to see a much smaller amount under the heading of calls in arrear. We all of us know, however, that in the City of London we have passed through a very critical and trying time, and no doubt many gentlemen have found it very difficult to meet all the claims upon them. I trust that in next year's accounts this item will disappear altogether. The liability for trade accounts includes, I may tell you, a substantial sum for reserve without there being any apparent probability of our being called upon to use it. The capital liability of £17,555 has been considerably reduced—in fact, almost paid off since September; but there are still outstanding liabilities for the completion of our Bushbury Works, and other matters which are in course of adjustment and settlement. The loan on provisional debentures has also been materially reduced out of our current receipts. The item of contingent liabilities is one which the auditors have dealt with in their report. Our contract, as far as contract goes, for the equipment of the Rathbone-place and Manchester-square stations of the Metropolitan Electric Supply Company are now almost completed, although there is a responsibility attached to the running of the machinery which does not expire for some time. With regard to the liability on shares partly paid up, there is not much probability of the contingent liabilities for calls becoming actual liabilities to any great extent. The matter is practically in our own hands, and calls of this nature upon our resources would arise only in the event of such a development of business on the part of the subsidiary companies as would be a matter of congratulation for all of us. As I have already mentioned, the whole of the preliminary expenses have been written off, and will not appear again. Now turning to the credit side of the account, you will notice that the purchase-money of £397,300 has been reduced by the value of stock and book debts. This is a matter of book-keeping only—the items reappear below. But you will also observe that the purchase cost of our businesses has been reduced by the further item of £100,000 for licences and patents sold, and this, you will agree with me, is not a mere matter of book-keeping, but a matter of considerable satisfaction and congratulation, and I hope this policy and our ability to adopt it will continue in future accounts. Our capital expenditure since the acquisition of the businesses has practically been limited to the new Bushbury Works. The cost of these works has been great, much greater than was originally contemplated; but we have felt ourselves bound to meet requirements, and our action will, I am sure, be justified by the increased capacity which it gives us for turning out work. I think this policy will commend itself to the shareholders—that although it is very good to make profits by means of subsidiary companies, still we must bear in mind that we must look to the payment of our future dividends to our manufacturing profits. It is, therefore, our duty to put this Company in the foremost rank of manufacturing companies. We have endeavoured to do that. It is not enough that we should have a character for turning out good work, we have that; but you must have a reputation for turning it out promptly, punctually, and with despatch. You must be able to turn out a large amount of work in a short time. We have had to refuse orders in the past year because we could not guarantee quick delivery. I hope that that will never occur again; and I believe that we have put at your disposal a factory which can be extended so as to meet all requirements that are likely to be made upon you in the future. I think when you see these works—and we had hoped to meet you there to-day—you will agree with us that your money has been very well spent. It is, in my opinion, the finest manufactory in the world as far as I know. The freehold ground on which the Bushbury works stand has an area of 21 acres. The works themselves occupy a space of over six acres. There is access to the London and North-Western Railway adjoining by means of a siding. The canal is close to one end of the place. There is excellent water on the property, and every facility for extending the works, and I think we could dispose at a profit of ground which we are not able to use for some years, or we might utilise such part of the property for the building of workmens' cottages. The item of book debts, amounting to £104,882, includes a claim upon the vendor for liabilities of the business purchased paid by the Corporation amounting to £12,091 odd. You must not assume this to be a case of over payment to the vendor. The amount which we paid to the vendors for the business was exactly the sum which we contracted to pay, but the conditions under which the vendor acquired the business of the Electrical Power Storage Company (Limited), and the conditions upon which we acquired the business from the vendor were a little different, and that leads to this result, which is satisfactory to us if not to the vendor. The vendor purchased the business at a price sufficient to pay all liabilities and a certain sum to the shareholders, and the calculation was apparently based upon the accounts as they stood at the previous stock-taking. We purchased the property from the vendor at a fixed sum, free from liabilities. Now it happened that between the period of the stock-taking and the purchase there had been an augmentation of business, which is not always usual in the case of businesses handed over to companies, and the result is that the assets and the liabilities in respect to those assets were alike increased. We took over the assets in accordance with our contract, and it was the duty of the vendor to discharge all the liabilities. Having regard to the difficulties of such a course in a current business, provision was made in our contract that in the event of our discharging any of the liabilities the vendor would recoup us the amount. Probably the vendor may have been surprised that the amount was so large; but the matter was gone into and equitably settled, and since the date of our report the claim has been settled. I do not think I have any further remarks to make about the accounts. Looking at the numerous applications which will be made for provisional orders in the future, and seeing the steady progress that has already been made by different supply companies, I do not think we can have any doubt as to the future of the electric light; but great as the field is in this

Digitized by Google

respect, I think it is likely to be eclipsed by the demand which will be made for electricity for other purposes. There are not wanting signs in this and other countries of activity in many branches to which electricity can be applied. In America the motor industry is even greater than that of the electric light. The electric light is said to be a luxury, but the time will come when it will be considered an absolute necessity ; and in the case of electric power, we are not only better than anyone else, but also cheaper. We then come to business men who do not spend a penny without expecting to get back for it a penny farthing. That is where I have great belief in the transmission of power by electricity. I was shown over a factory the other day, and the manager said to me that every new machine he laid down he would apply electricity to. At the Bushbury Works we use electricity for the cranes, saws, lathes, and heavy machinery. There is one point on which the Directors have been a little disappointed, that is in connection with train lighting. With my failing sight I speak very feelingly on this matter. Anyone going by the 5 o'clock train from St. Pancras must be convinced at once of the beauty and superiority of this method of illuminating the trains. In dealing with directors of railway companies however, you are dealing with a very conservative body of men, who are more inclined to look at first cost than the convenience of their passengers ; but I hope if any of you are shareholders in railway companies you will at their next meeting impress upon them the desirability of introducing this beautiful illuminant into their service. We have been more fortunate with electric traction. By the assistance of Mr. Smith—than whom, perhaps, there is no greater authority on this matter—we have been able to introduce electrical tramcars at Birmingham, where they are now working, and, I believe, in a very satisfactory manner. I hope this is only the first of a long series of similar installations. Seeing that we have these developments in electricity going on, that we have important contracts, and that we have incurred a large expenditure on new works, we think the time has come when we should ask you for more capital. We should have asked for this before, but the time has not been propitious, and acting on the advice of our financial advisers we have put it off. In order to enable us to secure the full advantage of the great boon, as I believe it will prove, in electric lighting and traction, we propose to issue £150,000 in 6 per cent. debentures. We have postponed this as long as possible, but we think we should now be neglecting your interests if we did not make the issue early next year at least. We hope these debentures will be to a large extent taken up by the shareholders, and I can assure you that the Directors will be quite prepared to take more than their share if necessary. There will, of course, be a public issue, so as to enable us to obtain a Stock Exchange quotation later on for them, but our own shareholders will receive the preference. I suppose all our shareholders are aware that we have a Stock Exchange quotation for our shares. That is all I have to say, and, after hearing any questions which shareholders may have to ask, I shall put the motion for the adoption of the report and accounts.

Mr. J. SPENCER BALFOUR, M.P. (the vice-chairman), seconded the motion.

Mr. MANDER spoke of the large interest which he and his friends had taken in the Company on account of their faith in the future of electricity. He regretted, however, to see that the Directors had been promoting companies instead of confining themselves to the manufacturing business.

Dr. DRYSDALE spoke of the great use of electricity for traction purposes in America, and asked whether the Directors thought it probable that electricity would be shortly used in London as the motive power for tramcars.

Mr. HANCOCK considered that the Board ought to place more to the reserve, in order to meet the expiration of the patents. He also urged the Directors to confine their attention to manufacturing instead of to the formation of companies.

Mr. JUDD thought that the Directors ought to be congratulated on the result of the sixteen months' working, seeing that the application of electricity to many purposes was still in its infancy. He thought that the Board, in forming subsidiary companies, had had in view the object upon which the previous speakers had laid stress, of enabling them the better to confine themselves to manufacturing.

Mr. BALFOUR: There are one or two questions which have been asked that I might probably reply to more easily, as I have been Chairman of the Finance Committee of the Corporation almost since its establishment. A suggestion was made by Mr. Mander, which I am disposed to view with considerable favour—that is as regards the Millwall depot, and I hope the time will come when we shall be able to concentrate the whole of the works of the Corporation—I cannot say under one roof, but in one spot in Wolverhampton. I quite agree that that would be desirable. It is so obvious a course, that Mr. Mander ought to give the Board credit for having thought of it at first. But the displacement of a large amount of machinery, a large staff, and the transfer of works such as ours, is a serious and somewhat expensive task, and the Board have had to proceed with caution in that respect. The works, as the Chairman reminds me, have only just been finished, and I think we are indebted to everyone for the success with which we have been able to shift over from one place in Wolverhampton to another without undertaking the more serious task at present in connection with the transfer of the Millwall works. I think there has been some misapprehension about the formation of subsidiary companies, and I thank Mr. Judd for the way he put that matter, and which is the correct way exactly. We have some patents which the Board are advised are of enormous value. Patents of that sort require development. In some cases, hostile interests have to be conciliated; in other cases inventors have to be brought in to assist, and in those cases it would be absolutely impossibly for the Company to go on with its ordinary work of manufacturing if it had to run these patents too. In such cases only have the Company sought to encourage the sale of patents to any sub-company, and in all such cases the sale has been made on such terms as will secure to the Corporation a very large share—certainly its full share—of the value of these patents until they are developed. It would be impossible for us ; how can we do manufacturing simply if at the same time our attention is taken up by sending people, say to Madrid, Constantinople or Rome, to deal with our foreign patents ? These matters must be dealt with by foreign companies, and the Board is under very great obligations to Mr. Courtenay—if the remark in question is meant to apply to that gentleman—for bringing his extensive knowledge, which is probably unrivalled in Europe on questions of electricity, and putting it at the disposal of the Company. As to our hour of meeting, it is difficult to please everyone. The Chairman says he had to get up at six to attend this meeting.

Another DIRECTOR: So did I.

Mr. BALFOUR: The Board would be very glad to hold the meetings of this Company at any time that was most convenient to the shareholders, but I do not myself think that there is much grievance in our meeting at twelve o'clock. With reference to the head office expenses, I expected the criticism. As the Chairman, however, has said, the head office expenses are for sixteen and the profits for only twelve months, so the same amount of expenses will not arise again. I have urged the Board—and I am sure they will do so now—that they should have more time at their disposal to overhaul the head office expenses, to see whether economies can be effected. It is, however, extremely difficult for us to cut our expenses down to the level of those of an ordinary business. We are asked for the price of equipping a local tramway, or of a large installation in some part of the country. The man whom we send down to report on such a thing as that—who has to get out the figures, arrange the drawings, and to meet the various local authorities ; the man, in fact, who has to secure the business, must be in manner, bearing, and address a gentleman. He must be highly paid, or he would be open to bribery and so on. These expenses must be large if we are to retain some of the most profitable work that we have. I shall, however, watch the expenses. The whole business of my life is to put down expenses whenever I can, and my services are at the hands of the Corporation to secure that end here. With respect to the remarks of Mr. Hancock, I do not think that he should really have put it that we have any cause for disappointment for these figures, or the dividend which is proposed to be paid. Remember these accounts have not been got out or put together, or "cooked" by the Directors. We have made it a *sine quâ non* from the first that our accountants should give us a continual audit, that our accounts should be under supervision from week to week and day to day, and that they should be under the supervision of a firm of high standing in London. Our auditors are coming in at every moment. They see our growth, and they know every item of the business ; and I venture to say that if we had not had the restraining influence of the auditors, and did not wish ourselves to pay only a moderate dividend, we could have shown a much more favourable result. Our policy, however, has been to over-estimate expenses, and to under-estimate profits, so that we might produce accounts which we would all stand by. One or two questions were asked which I do not think we need say anything more about after what I have said about company-mongering. With respect to the issue of Debentures at 6 per cent., we should all agree that 6 per cent. is a good rate to pay on Debentures ; but I think shareholders will realise, if they watch the market, that most industrial companies of this kind have still to pay 6 per cent. on their Debentures. We can, however, make the rate 5 per cent. as easily as possible if the shareholders will only take up the Debentures and only accept 5 per cent. We should be perfectly ready to issue them at that price. I am quite prepared, and so are the other Directors, to take their proportion of Debentures bearing 5 per cent., and if the shareholders will only do the same, we can issue them at once at this lower rate. We have, however, to study the market, and to remember that electrical companies are still viewed with disfavour, a feeling which I believe that this report will do much to dissipate. As to electrical traction for tramways, I was a few days ago in the north of England, and one of the most eminent engineers of the day volunteered a very interesting statement to me. He said he had been to Birmingham, and speaking about the working portion of the tramways there, the motive power for which is electricity, he said he considered that the question was solved, and solved in the direction they were wishing. He also said that he regarded the work there as of the utmost importance, and redounding to the credit of this Corporation and everyone connected with it. We have seen nothing to cause us to doubt of its ultimate success, and, as far as the report is concerned, we have taken pains to present you with an honest, trustworthy, and faithful statement.

The CHAIRMAN said he thought that the whole of the questions that had been put had been answered by the Deputy-Chairman, and therefore he put the motion for the adoption of the report and accounts.

The resolution was carried unanimously.

The CHAIRMAN next proposed the declaration of the dividend recommended.

Mr. BALFOUR seconded the resolution, which was carried.

On the motion of the CHAIRMAN, seconded by Dr. DRYSDALE, the retiring Directors, Sir Daniel Cooper, Mr. Balfour, Mr. Courtenay, and Mr. Dibley, were re-elected to their seats at the Board.

Sir DANIEL COOPER, in acknowledging the re-election of himself and colleagues, stated that he was connected with the old E. P. S. Company for seven years, and he could bear out what the Deputy-Chairman had stated as to the difficulty of managing the foreign portion of their patents. Mr. Courtenay and himself were both Directors of the old E. P. S. Company, and that part of their duties, which occupied most of their time and attention, and which gave them most annoyance and dissatisfaction, was the foreign portion of the patents. The idea of persons in London working patents on the Continent was a mere delusion, and, therefore, the forming of their subsidiary companies had been almost a matter of necessity. It was better to throw the foreign patents away altogether than to try and attempt to work them from

Digitized by Google

London, and, therefore, anything which they got at all out of these patents would be so much profit. This could only be done through subsidiary companies. It was impossible to get a profit in any other way. What had been done in the case of this Corporation in forming subsidiary undertakings had had nothing whatever to do with company-mongering.

Mr. MANDER suggested the appointment of Mr. Parker to fill the vacancy on the Board.

The suggestion gave rise to some discussion, it being considered that the appointment of that gentleman as a Director would be incompatible to his present position as an executive officer of the Company. Eventually the proposal was withdrawn.

The retiring Directors were reappointed, and a vote of thanks to the Chairman and Directors brought the proceedings to a close.

## Reuter's Telegram Company (Limited).

A special meeting of this Company was held at 24, Old Jewry, on the 6th inst., when resolutions were submitted for increasing the capital and extending the business of the Company. Admiral the Right Hon. Sir J. C. Dalrymple Hay, Bart., K.C.B., presided, and Mr. John Hart, of 22, Great Winchester-street, the solicitor, was in attendance.

The SECRETARY (Mr. Walter F. Bradshaw) having read the notice convening the meeting,

The CHAIRMAN said: Gentlemen, you will observe that the two resolutions which are to be submitted to you are interdependent. I shall, therefore, speak to both resolutions in the few words which I shall have the honour of addressing to you. The resolutions will eventually have to be moved separately, but unless both were carried they would be inoperative. Before moving the adoption of the resolutions which have just been read by the Secretary, I will briefly explain to the meeting the objects we have in view is asking an extension of the powers of the Company and an increase of its capital. At the outset, let me remove from your minds any idea you may entertain that our present capital is found insufficient for our existing business. It is true that we have to incur considerable expense in keeping abreast with the growing demands for telegraphic intelligence, but at present our capital is adequate for all purposes connected with that branch of business so far as it is necessary to provide agents and correspondents with funds. It may be found advisable, in the interest of our subscribers, to supplement existing services with special accounts of remarkable events, trials, fires, &c., on a larger scale than has hitherto been considered necessary, or within the scope of our general service. These, however, would be the subject of further consideration in conjunction with the newspapers themselves, and would, doubtless, be met by contributions which would recoup our outlay. The primary object of the proposed alteration of our Memorandum of Association and the increase of our capital is to enable us to undertake a class of business for which our organisation seems particularly adapted, namely, the collection of advertisements for the newspapers who are our supporters. The idea has long been entertained by our Managing Director, who has not failed to notice the great expansion of advertising of late years. The most conservative and old-fashioned firms now find it necessary to resort to this mode of attracting public attention. Until recently the law regarded a Memorandum of Association as unalterable; consequently, to carry out the project in the past it would have been necessary either to dissolve the Company and found a new one, or to form a subsidiary Company, both courses obviously open to grave objections. Fortunately during last Session of Parliament an Act was passed empowering Companies, under the sanction of the High Court, to enlarge the sphere of their operations, and we have decided to avail ourselves of this power with your approval. I will read the section of the Act which is applicable to our case:—"1.—(1.) Subject to the provisions of this Act, a company registered under the Companies Acts, 1862 to 1886, may, by special resolution, alter the provisions of its memorandum of association or deed of settlement with respect to the objects of the company, so far as may be required for any of the purposes hereinafter specified. (d.) To carry on some business or businesses which under existing circumstances may conveniently or advantageously be combined with the business of the company." It must be obvious that with agencies in all the capitals of the world, who are brought into direct communication with the newspapers, this Company has exceptional means of establishing an international advertising business on a large scale, with, we believe, immense advantage to our subscribers. We, in fact, seek to create a new business for the newspapers as well as for ourselves. Some apprehension has been expressed in certain quarters that the working of an advertisement business may prove detrimental to the telegraphic service, inasmuch as the latter has to deal with financial affairs and many things that advertisers might influence. Upon this matter, we can only point to our reputation and ask if it is likely that your Directors would commit the suicidal folly of allowing any advertiser to influence the impartiality, which, we may say without boasting, has been the characteristic of our service since its creation. Indeed, it has been made a ground of reproach that our impartiality has been carried to such a length, that we too drily chronicle events. As a safeguard, however, it is proposed to keep the telegrams strictly apart from the advertising branch, and a separate staff will manage the latter in separate offices. Our editors will no more be brought in contact with the advertising branch than are the editors of the London papers with the advertisements which appear in their columns. We are sanguine that the new business will be found a good source of revenue, but we must warn shareholders against looking for increased dividends at the commencement. The organisation of an international business takes time, and can only be accomplished after much negotiation. We have, however, taken preliminary steps abroad in conjunction with the largest advertising agency on the Continent, and as soon as we shall have obtained your approval of the resolutions now submitted to you and the sanction of the High Court, as enjoined by the Act, we shall be ready to start the new machinery. In addition to advertisement business, we believe it may be found profitable to undertake telephonic and other services, which would become feeders, as it were, of our trunk system. In short, the enlarged powers we seek to obtain will enable us to extend our business in many directions that are now barred by our restricted Memorandum of Association. With these few words I now propose the first resolution, which you have in your hands as follows:—

"*That the capital of the Company be increased to £100,000 by the creation of 2,500 new shares of £8 each, and that the Directors be forthwith authorised, under the provisions of Clause 26 of the Articles of Association of the Company, to issue such shares.*"

Baron DE REUTER briefly seconded the resolution, observing that he had nothing to add to what had been said by the Chairman, who had explained everything so ably that he believed that what was proposed would be thoroughly understood.

The CHAIRMAN put the motion to the meeting in the usual manner, and declared it carried unanimously. Continuing, he said: The second resolution is as follows:—

"*That subject to the provisions of the Companies (Memorandum of Association) Act, 1890, the provisions of the Memorandum of Association of the Company with respect to the objects of the Company may be altered as follows, that is to say, by expunging sub-sections 2 and 3 of Clause 3 of the Memorandum of Association and by inserting in lieu of the sub-sections so expunged the following sections:—*

"*(2) To carry on and extend the said business and generally to carry on, acquire, obtain, and supply telegraphic, telephonic, or other news and intelligence and to issue, publish, and circulate, and otherwise utilise, with a view to the profit or advantage of the Company, the same news and intelligence.*

"*(3) To carry on in the United Kingdom, and in any part of the world,*

PATENT

*the business of general advertisement contractors and advertising agents in all its branches.*

"*(3a) To construct, purchase, hire, or otherwise acquire, or work telegraphs and telephones for any of the purposes hereinbefore mentioned.*"

I propose that the resolution be passed.

Baron DE REUTER seconded the motion, which was unanimously adopted.

The CHAIRMAN: The business upon which we are assembled is now completed. I may, perhaps, mention that I hold in my hand proxies for 496 votes of shareholders, so I think that our proposals are very generally acceptable to our shareholders. On the 23rd inst. there will be a meeting, according to the Act, to confirm the resolutions passed to-day. I thank you for your attendance.

The meeting then separated.

## The Gulcher (New) Electric Light and Power Company (Limited).

The following is the report of the Directors of the Company for the twelve months ended June 30th last, to be presented to the third ordinary general meeting to be held at Winchester House, E.C., on Thursday, the 18th inst., at 12 o'clock.

The Preference capital of the Company, which on June 30, 1889, consisted of 12,277 Preference shares, having £12,241. 1s. 4d. paid up, consisted on June 30, 1890, of 50,000 Preference shares, having £30,797. 8s. paid up. The £10 per cent. Second Debentures, which, on June 30, 1889, amounted to £8,862. 10s., and, which, at the date of the last report had increased to £16,000, were on June 30, 1890, reduced to £400. This satisfactory alteration of the capital account is mainly due to the response made by a limited number of shareholders to the prospectus issued on January 1st last, inviting subscriptions for the then un-issued Preference shares. The central stations for the public lighting of Wellington, New Zealand, upon which on June 30, 1889, the Company had expended £9,598. 18s. 8d. were shortly afterwards completed. On June 30, 1890, this important installation stood as a debtor in the Company's books for £13,486. 13s. 3d., since which time the amount has not been increased.

The Directors, in their last report, pointed out to the shareholders that the commercial success of this undertaking would depend entirely upon the provision of further capital for private lighting. They concluded, however, after careful consideration, not to lock up so large a portion of the newly subscribed capital as would be necessary to enable the Company exclusively to provide for this private lighting. A well-supported Syndicate has accordingly been formed, which will not only provide for the private supply of the town, but will ultimately take over this Company's business in New Zealand, together with the benefit of the contract for the public lighting, entered into between this Company and the Mayor and Corporation of Wellington.

The particulars of the contract between the New Zealand Electrical Syndicate and this Company, and of other contracts undertaken and carried out during the past year, will be supplied at the general meeting, when a detailed profit and loss account will also be submitted to the shareholders.

In the autumn of last year this Company contributed towards the registration of the South-Western District and Thames Valley Electricity Supply Company (Limited), from which the Directors have reason to anticipate good results.

The gross manufacturing profits for the year ended June 30, 1890, amounted to £3,097. 2s. 4d., which, compared with the manufacturing loss of £1,417. 6s. 6d. in the preceding year, must be regarded with satisfaction. The heavy interest payable on the Second Mortgage Debentures (nearly all of which, however, have now been paid off) has alone prevented the declaration of a dividend.

Since the last general meeting, Mr. Binswanger has resigned his seat at the Board. The Directors, under the powers conferred on them by the Articles of Association, recently elected Mr. C. S. B. Hilton, a large shareholder, to assist in the direction of he Company. Mr. De Castro and Mr. Hilton retire from the Board, but being eligible, offer themselves for re-election. Mr. Russell Day, the auditor appointed at the last general meeting, also retires, but offers himself for re-election.

## NEW COMPANIES REGISTERED.

**MARINE AND GENERAL AUTOMATIC COMPANY (LIMITED).**—Registered by Andrew, Wood, and Co., 8, Great James-street, Bedford-row, with a capital of £20,040, in 4,000 ordinary shares of £5, and 40 Founders' shares of £1 each. Object: to acquire certain patents for the invention of improvements in automatic electrical tell-tale apparatus, in accordance with an agreement made August 26 between W. T. W. Thackeray, J. Huer, and J. Davies, as vendors, of the one part, and J. Knowles, as purchaser on behalf of the Company, of the other part.

**NEW COMPANIES IN NOVEMBER.**—The following is a list of the new electrical and engineering companies registered in November:—

| | |
|---|---|
| Anglo-Mexican Saw-Mills Company, in £1 shares | £5,000 |
| Chagford and Devon Electric Light Company, in £1 shares | 2,000 |
| Deflector Safety Lamp and Miners' Appliance Company, in £5 shares | 20,000 |
| Electricity and Electrical Engineering Newspaper Company, in £10 shares | 500 |
| Electrolytic Syndicate, in £1 shares | 100,000 |
| Ernest Scott and Mountain, in £10 shares | 70,000 |
| Financial Exchange and Bureau, in £100 and £2 shares | 10,000 |
| Heyford Iron Company, in £10 shares | 20,000 |
| Holmes and Sons, in £5 shares | 14,000 |
| Horsham Ironworks, in £5 shares | 5,000 |
| Plenty and Son, in £10 shares | 25,000 |
| Sleeman Controlled Torpedo Syndicate, in £1 shares | 12,000 |
| South Indian Railway Company, in £10 shares | 1,000,000 |
| South Molton Shirt and Collar Manufacturing Company, in £10 shares | 5,000 |
| United Alkali Company, in £10 shares | 6,000,000 |
| Weymersch Electric Battery Syndicate, in £5 shares | 20,000 |

**PLENTY AND SON (LIMITED).**—Registered by R. Jordan, 120, Chancery-lane, with a capital of £25,000 in £10 shares. Objects: To acquire the business of marine, general, and mechanical engineers carried on by Plenty and Son, at the Eagle Ironworks, Newbury. The first Directors are:—Earl Russell, E. P. Plenty, and H. Wethered.

**STEAM LOOP COMPANY (LIMITED).**—Registered by Slaughter and May, 21, Great Winchester-Street, E.C., with a capital of £70,720 in £1 shares. Object: to carry into effect an agreement made between John Gillespie and the Company to carry on the business of mechanical and general engineers, machine and engineering tool makers, iron and brass founders, metal workers, and steel converters, &c.

## CITY NOTES, &c.

**BRAZILIAN SUBMARINE TELEGRAPH COMPANY.**—The receipts of this Company for the week ending December 5th amounted to £5,955.

**DIRECT SPANISH TELEGRAPH COMPANY.**—The traffic receipts of this Company for the month of November amount to £2,722, as against £2,497 for the corresponding period last year.

**RICHARD HORNSBY AND SONS (LIMITED).**—At the annual meeting, held on Wednesday, a resolution declaring a dividend of 6 per cent. was carried.

**NATIONAL TELEPHONE COMPANY.**—This Company has declared an interim dividend at the rate of 5 per cent. per annum for the six months to October 31st last, payable on the 20th Inst.

**STOCK EXCHANGE.**—The Committee have ordered the following security to be entered in the official list:—Eastern and South African Telegraph Company (Limited), £201,000 Four per Cent. Mortgage Debentures Nos. 1 to 2,016.

**WESTERN AND BRAZILIAN TELEGRAPH COMPANY.**—The traffic receipts of this Company for the week ending December 5, 1890, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £4,667.

# THE NON-CONDUCTOR OF ELECTRICITY.

**VULCANISED FIBRE,**

PATENTED.

**This new material is supplied in two qualities, Flexible and Hard.**

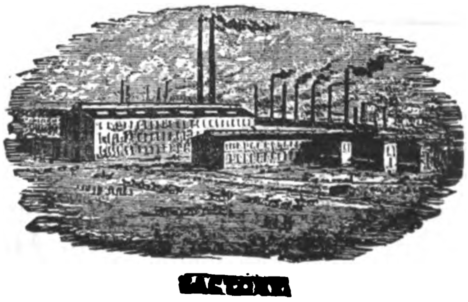
**The FLEXIBLE is a substitute for Leather, Rubber, Gutta Percha, &c., and is extensively used by Brass Founders, Axle Makers, Hydraulic, Sanitary, and other Engineers, Pump Makers, Carriage Builders, &c.**

**It makes the best Hot and Cold Water Packings, and for Axle Washers of all kinds it is unequalled.**

**The HARD is a substitute for Metals, Hard Wood, Ivory, Vulcanite, Ebonite, &c., and is a good Insulator.**

**Sold in sheets, 5ft. 6in. by 3ft. 6in., varying in thickness from 1-50in. to 1in.**

**FLEXIBLE, 2/- per lb.; HARD, 2/3 per lb.**



**MOSSES & MITCHELL, 70, Chiswell-st., London, E.C.**

# THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

## ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 657.—Vol. XXVI. FRIDAY, DECEMBER 19, 1890. Price Fourpence.

## NOTES.

The City and South London Railway was opened yesterday, and a continuous service of trains ran throughout the day. We found a considerable number of passengers at the Monument Station, many of them preferring to use the stairs than the capacious but somewhat leisurely-worked lifts. The line has not been ballasted, as was suggested, the idea being that this would reduce the noise. Conversation is possible, and indeed was carried on between the passengers, but with considerably more effort than on the Metropolitan line. The carriages are lighted with glow lamps, and these, though not very important, are the least satisfactory part of the work. During our visit the dynamos were for some reason excited only by the shunt coils, though the turn of a switch would have compounded them. The result was that every time the train started from a station the illumination fell very considerably, and when one train was standing at a station while another was starting in the adjacent tunnel the same effect was visible. On climbing the steep gradient and severe curve, on the return journey, near the terminus, the lamps were merely red hot. On visiting the engine-room at Stockwell, we found two engines at work and one turning round. The needles of the ammeters on the four different feeders were moving slowly between 50 and 100 amperes. The speed of the engines was fairly regular, but the volts, as shown by Sir William Thomson's engine-room voltmeters, fluctuated from about 370 to 460.

About half of the passengers appeared to be "boná fide travellers," but that there were a number who were bent on an errand of curiosity was evinced by the attempts which were being made at Stockwell to prevent passengers from the City going across the platform to the next returning train, and thus defrauding the Company of a twopenny fare. An evening paper last night mentioned that some hitch occurred early in the day, but all was going well in the afternoon; about a thousand persons had passed the Stockwell turnstiles by mid-day, and some ten times that number were recorded at the Monument Station at seven o'clock, when the approach to the station was crowded. The time from Stockwell to the City was about 20 minutes. The atmosphere was perfectly pure, and was distinctly warmer than on the surface. We understand that some delay in opening has been caused owing to mechanical difficulties which have now been overcome. They related in no way to the electrical part, but concerned the coaches and their springs. We cordially hope that the extensions to Clapham and to Islington may result from a satisfactory working of this unique and boldly designed railway.

The general knowledge of secondary batteries has been undoubtedly advanced by the two Papers which have been presented to the Institution of Electrical Engineers and the long discussions which have followed them. It is suggested that the information, or at all events so much of it as is of importance, has been known to the manufacturers, who have kept it to themselves. The results are remarkable for their reliability, as being the outcome of a large amount of solid work, rather than for any startling novelty. The authors of the Papers are to be congratulated on having placed the accumulators under the actual conditions of ordinary work, instead of endeavouring to attempt to bring out some interesting scientific point, which might or might not throw light upon the theory, but which would be of little or no use to the engineer. The theory, as we have recently remarked, is not much advanced.

There are some chemists who would inflict elaborate formulæ upon us, and others, perhaps, who would begin at the other end, and may be inclined to follow Mr. D. G. Fitzgerald, who asks for what reasons the authors called the peroxidised plate the positive. In his brief reply Prof. Ayrton did not have time to answer this question, and we therefore take this opportunity of giving an answer of a thoroughly convincing character, and one which we venture to recommend to every student, since it is easy to remember. The *P*ositive plate of a secondary battery is properly so called because it is *P*eroxidised and *P*lum-coloured; the *N*egative plate, on the other hand, is of a *N*eutral colour, and is *N*ot oxidised.

The suggestion that the peculiar red coloration of cells which was illustrated in our last issue is due to gold is interesting. It has always been difficult to account for the huge quantities of that metal which have been spent, and we thought lost, in storage batteries during the last nine years.

An explanation of the rise of resistance of a secondary battery during discharge was put forward some years ago by Mr. Lane Fox, and is worthy of record while the subject is still before us. He suggested that a film of pure water is produced on the surface of the plate, and that this gives rise to the increase of resistance. It should not be difficult to prove this.

THERE has been a general impression for the last few years that selenium is a fraud. The experiments of WILLOUGHBY SMITH, ADAMS, TAINTER, and GRAHAM BELL led us to imagine that the now forgotten photophone was to be the immediate forerunner of an actual method of seeing by electricity, a method so easy to describe and talk about, and so difficult to carry into practice. Numerous arrangements have been suggested, and great ingenuity expended in devising receivers. Glow lamps, vacuum tubes, sparks, moving mirrors, sensitive gas flames, NEWTON's rings, and drops of fluid in a beam of polarised light have been put forward for this purpose. For the transmitter, selenium has always been used where any attempts have actually been made. Mr. LL. B. ATKINSON has made many experiments, and suggested a mixture of carbon and sulphur and bromide of silver, since he found, as all others have done, that selenium is liable to great variations in sensitiveness, and is of too small conductivity. The question of variation of sensitiveness has, however, been cleared up by Mr. SHELFORD BIDWELL, in his communication to the Physical Society last week, and his discovery of the electrolytic formation of selenide of copper removes the doubts which have existed as to the trustworthiness and durability of this material. Future experimenters will now be on their guard, and will either seek a metal which is not attacked by selenium, wherewith to make the cell, or will, at all events, protect the wire with which it is wound.

THE introduction of condensers which can be applied to alternate-current circuits may lead to a new departure in electrical engineering. Hitherto condensers have not been used outside the laboratory except for the purpose of telegraphy, and here the currents and pressure are so small that no serious troubles are met with other than may be due to ordinary insulation. But a number of difficulties arise when an attempt is made to construct a condenser which can comfortably accommodate an ampere which is being urged to and fro under two or three thousand volts. Dielectrics, whose homogeneity and elasticity were never considered when a few batteries were at work on them, are found to absorb and degrade energy into heat at a rate which is measured by horse-power. A system of distribution by means of condensers was described by Dr. DOUBRAVA in *The Electrician*, Vol. XXII., p. 676, and there he states that an area of one metre and a cost of eight shillings is sufficient for a 16-candle lamp. M. JABLOCHKOFF has experimented in this direction, and Mr. BLAKESLEY's work, of a very different order, though somewhat premature, will probably be re-read with interest, while Mr. SWINBURNE's complete paper, of which we publish an abstract this week, breaks entirely fresh ground and may lead to very important results.

THE modern electrician, if he seeks to investigate for himself the most recent developments of science, has to deal with periods which are measured in hundredths of thousandths of a second; and any means of making a contact of a well-defined, strictly calculable, and short duration, is at the present moment of considerable importance. In connection with this the following extract from a letter which we have received from Sir WILLIAM THOMSON will be read with interest, together with a further communication on the subject, which will be found in our correspondence columns.

"I should have said, but did not do so for want of time, in our conversation in the 'Physical' yesterday evening, that the method of discharge by impact of metal balls may be used to show electric oscillations in the discharge of a Leyden jar. For many years I have wished to do this, and a fortnight ago, as a preliminary, I began to work out the mathematical problem of calculating the duration of a collision between two perfectly elastic solid globes, which I had found to be invariably as the fifth root of the velocity of approach. Only last Tuesday I found that the problem had been fully solved by Boussinescq (1884) in his great book on Elasticity of Solids, and that 'Heinrich Hertz' (*Crelle's Journal* Vol. XCII., 1882) is referred to by Boussinescq with thorough and generous appreciation, as having anticipated him. Thus, from Hertz himself comes a fresh contribution to the investigation of electric oscillations quite unexpected, I believe, by any of those who last week welcomed the mark of approbation conferred on him by the Royal Society for his more recent great work on electric waves and oscillations."

ELECTRICAL engineers would do well to glance occasionally at some of the journals devoted to the gas industry. They will find an inveterate opposition to electric lighting, as may naturally be expected; but, on rare occasions, among the criticisms, which, after all, show a much more creditable knowledge of the subject than is exhibited by the daily press, they may find such an article as that which we reproduce in this issue. The ventilating power of gas, if we may use the expression, is merely that of the furnace in the upcast shaft of a mine. It depends quite as much upon the shaft as on the furnace; the former may, indeed, be said to be more essential than the latter. Practically, the desideratum is a sunlight with an ample flue. If electric light be used in the sunlight, it would be well to put a few gas-burners immediately above them, within the flue; and as their light is not wanted, and their radiant heat is objectionable, Bunsen burners would be better; in fact, a good ordinary gas fire might be used. The be-littling of the value of oxygen, or of its consumption, is carried rather too far by the writer of the article to which we have alluded. It is true that the occupants of a room need fresh air, but a gas-burner needs seven times as much. The remarks about the hall of the Society of Arts are none too strong, and for many years the ventilation of the theatre of the Royal Institution was a standing disgrace.

WE published, on page 559 of our last volume, a short article by Dr. SHELDON on the "Magneto-Optic Generation of Electricity," which described experiments attempting to show that a minute electromotive force is induced in the coils of a solenoid when its core is traversed by a beam of light, the plane of polarisation of which is rapidly changing. The article in question has been considerably criticised, and Dr. LODGE has pointed out that the experiments described cannot be accepted as conclusive owing to the neglect of certain precautions in conducting them. In the December number of the *Philosophical Magazine* Prof. ANDREW GRAY discusses the matter further, and gives reasons for supposing that the induced electromotive force can only occur when the angular velocity with which the polariser rotates is changing in magni-

Digitized by Google

tude. If this is the case a current may be produced by oscillating the polariser backwards and forwards, but cannot arise from uniformly rotating it, however rapid the rotation may be. It appears that several years ago Prof. GRAY experimented with the same object in view, using a beam of circularly-polarised light. The light passing through the solenoid was alternately cut off and restored by a rapidly rotating perforated screen. The experiments failed owing to the minuteness of the effect under examination; but the idea that a circularly-polarised beam of light produces a magnetic field is confirmed by an investigation in Prof. J. J. THOMSON's "Applications of Dynamics to Physics and Chemistry," where the magnetic field, due to a beam of strong sunlight, polarised in the manner described, is calculated numerically We would suggest that a more satisfactory method of oscillating the polarised ray would be to discharge a Leyden jar through a suitable solenoid in the manner adopted by MM. BICHAT and BLONDLOT, and Dr. OLIVER LODGE. The beam of light might be parallel, and the receiver could then be placed at a considerable distance, so that no direct electrical effect could be produced.

ONE of the most striking ways in which mathematics can be applied to help onward physical science arises from the power which it sometimes shows of deducing from a few well-known facts and principles conclusions with regard to new and apparently disconnected phenomena. The above instance is a case in point. The number which Prof. THOMSON has arrived at can be used to deduce the electromotive force caused by the new magneto-optic action in any particular case, and but very little calculation suffices to show that the effect in question is, after all, far too minute to be detected by ordinary experimental methods.

**Maidstone.**—The Town Council has decided to apply for a Provisional Order.

**A Daily Electrical Journal.**—On and after January 1st the *Elektricitäts Zeitung*, of Berlin, will be published daily.

**South Shields.**—At a recent special meeting of the Town Council, a resolution was unanimously passed to make application for a Provisional Order.

**Electrical Patents.**—Last year the number of patents granted was 19,507, of which 1,082, or 5·57 per cent., were connected with electricity, against 19,295 and 1,109 (5·7 per cent.) respectively in the corresponding period of 1888.

**Special Notice.**—We desire to call attention to the fact that *The Electrician* will be published on Wednesday, the 24th, instead of on Friday, the 26th December, so that all contributions intended for the Christmas-week issue must reach us by mid-day on Tuesday at the latest.

**Electric Lighting at the Guildhall.**—At the last meeting of the Common Council it was resolved:—"That it be referred to the City Lands Committee, to consider and report as to the desirability of fitting the Guildhall and offices with an installation of electric lighting and the probable cost thereof."

**Instruction of Electrical Engineers.**—In the Authorised Abstract of the discussion on Prof. Ayrton's Paper on "The Chemistry of Secondary Cells," the third word from the end of last sentence but one of Mr. King's remarks (*The Electrician*, December 12, p. 177) should be *circuit* instead of *surface*.

**National Telephone Electrical Society.**—On Friday, December 5th, in connection with the Midland branch of this Society, the vice-president (Mr. A. E. Cotterell) gave a very interesting and instructive paper on "A few Errant Notions on Telephonic Matters."

**Swan Patent Litigation.**—Judgment was given on Monday last in the Supreme Court of Appeal, Leipsic, in the case of the Allgemeine Elektricitäts Gesellschaft (formerly the German Edison Company), *v.* The Swan United Company, in favour of the Swan Company.

**Bristol.**—On Friday last week, the members of the Electric Lighting Committee of the Bristol Town Council visited Bath, accompanied by Mr. Preece. On Saturday the Committee held a consultation with Mr. Preece at Bristol, the outcome of which was that Mr. Preece was instructed to prepare an estimate for a central station to supply current to 60 arcs and 10,000 incandescents.

**The Electricien and the Revue Internationale de l'Electricite.**—On and after the New Year, the *Electricien* and the *Revue Internationale de l'Electricité* will be amalgamated under the title of *L'Electricien, Revue Internationale de l'Electricité et de ses Applications*. All communications, therefore, connected with subscription, rates, &c., must in future be addressed to M. Georges Carré, 58, Rue Saint-André-des-Arts, Paris. M. Hospitalier will not, we regret to hear, continue as editor of the amalgamated journal.

**Personal.**—The staff of the Technical College, Finsbury, have presented to Prof. William Robinson, their late colleague, on the occasion of his appointment to the Professorship of Engineering at University College, Nottingham, a handsome and massive dining-room clock, having the arms of the City and Guilds of London Institute engraved on it, along with an appropriate inscription.

**Spanish Cables.**—Messrs. Pirelli and Co. write us that we were in error in the note in our issue of the 5th inst., in giving their address at Turin. This, of course, should be Milan. They further inform us that the cables for which they have obtained the contract are not to be maintained during ten years at their expense, but that they have only to warrant the good working of them during the first year. The contract price is about £160 per mile.

**"Electrical, Mechanical, and Milling News."**—This journal will, on and after the New Year, be published under the title of the *Canadian Electrical News and Steam Engineering Journal*. "It will be the object of the *Electrical News* to make known as widely as possible the methods by which electricity may be made to serve the interests of mankind. . . . It will endeavour to bring about at the earliest possible date the organisation of a Canadian Electrical Association."

**The Barking-road Line.**—The accumulator cars operating on the Barking-road section of the North Metropolitan Tramway Company during the five months ending November ran 27,597½ miles out of a possible 27,833 miles, the loss of mileage from all causes amounting only, therefore, to 235½ miles, or ·844 per cent. These figures are confirmed by the North Metropolitan Tramway Company. On the 28th of last month, when there was a heavy fall of snow, the cars performed 193 miles out of a possible 213. This is a better average than was made by the horse cars.

**The Lighting of the City.**—At the meeting of the City Commission of Sewers on Tuesday last, a report from the Streets Committee was brought up relative to the tenders for lighting the western district of the City by electricity. It recommended that the proposal of the Brush Electrical Engineering Company, on similar terms to those contained in the agreement for the central district, be accepted. It also suggested, in regard to an application by that Company for the consent of the Commission to their Provisional Order, that such consent should be given subject to a contract being executed as in the case of the central district.

**The Westinghouse Company.**—During the month of November, the shipments of the Westinghouse Electric and Manufacturing Company are stated to have amounted to 40 alternators, having a total capacity of 30,000 sixteen candle-power lamps. To this must be added 1,200 alternate current meters. The Westinghouse Company has now increased the capacity of its motor department to an extent which enables them to manufacture 100 motors per month. The Company, it is further stated, has at the present time 50 new electric street railways under construction.

**Globular Lightning Experiments.**—Planté, as is well known, used a huge secondary battery in his globular lightning experiments. Herr von Lepel states that similar effects may be observed by placing a sheet of mica, ebonite, or glass between the poles of a powerful influence machine, the best results being obtained with glass or paper discs rubbed with paraffin. If the tension is not too great, little luminous red balls may be seen moving about on the discs. Herr von Lepel is of opinion that small particles of dust or liquid are the chief causes of the phenomenon. A slight puff suffices to extinguish the glow, which disappears with a hissing noise.

**The Electric Welding of Projectiles.**—At the reading of a Paper on this subject before the Boston Society of Arts, Lieut. Wood, of the United States Navy, exhibited several specimens of electrically welded shells. One of these had been fired against heavy steel armour, much heavier than a projectile of the size could be expected to perforate. It, however, penetrated 5in., and then, owing to the elasticity of the oak backing of the plate, was thrown back about 30ft., as perfect in condition as before it was fired from the gun. The experience of the Welding Company had been, said Lieut. Wood, that the metal seemed to be strengthened at the point of welding, and this certainly tended to justify the supposition.

**The Electro-Deposition of Aluminium.**—According to the *Electrical Engineer*, of New York, Mr. Jeançon employs for this purpose a saturated solution of persulphate of aluminium requiring the high temperature of about 180° to 200° Fahrenheit to prevent crystallization. The anode is of commercial aluminium having incorporated with it a separating substance affected neither by the current nor by the solution. This is prepared by melting the aluminium in a crucible, and stirring in about 30 per cent. of carbon or some other similar substance. Mr. Jeançon finds carbon to be preferable, and the union, which is probably largely mechanical, is facilitated by the presence of a small quantity of hydro-carbon. The process described is claimed to give a dense reguline deposit of aluminium.

**A Freak of Lightning.**—The usual monthly meeting of the Royal Meteorological Society was held on Wednesday evening at the Institution of Civil Engineers. Among the papers read was :—"Note on a Lightning Stroke, Presenting Some Features of Interest," by Mr. R. H. Scott, F.R.S. On January 5th a house near Ballyglass, county Mayo, was struck by lightning, and some damage done. A peculiar occurrence happened to a basket of eggs lying on the floor of one of the rooms. The shells were shattered, so that they fell off when the eggs were put in boiling water, but the inner membrane was not broken. The eggs tasted quite sound. The owner's account is that he boiled a few eggs from the top of the basket, the rest were "made into a mummy," "the lower ones all flattened, but not broken."

**A Bibliography of Recent English Electrical Literature.**—We have received from Mr. H. E. Hafferkorn, of Milwaukee, U.S.A., Part II., "Electricity and Magnetism," of his "Handy Lists of Technical Literature." This publication is a reference catalogue of books on Electricity and Magnetism printed in English from 1880-1890 inclusive, and it also contains a select list of books printed before 1880, and still purchaseable. Works are entered under their authors' names, and there are also subject headings in the same alphabetical series as the authors' names. This bibliography is well-planned, clearly printed, and contains full information as to prices, publishers, editions, &c. It appears, moreover, to fairly well cover the ground. This catalogue should prove most useful to electrical students and writers.

**French Cable Enterprises.**—The Société Française des Télégraphes Sous-Marins announces the opening to the public of the Martinique-Paramaribo cable. The cable connecting Paramaribo to Cayenne is now being manufactured, and will be laid early next year. The Cayenne-Vizeu section will then be taken in hand, and Brazil will thus be in telegraphic communication with the West Indies and North America *via* the cables of the Société Française. The announcement then concludes as follows :—"This Company proposes, with the help of the factory erected at Calais by the Société Générale des Téléphones, to render France at last independent of England in all that concerns the submarine telegraphic connections that she may desire to effect."

**Electricity in Railway Working.**—In a report to the Board of Trade on the collision which occurred on October 11th, near Gorgie station on the suburban section of the North British Railway, Major Marindin says :—"The best way to prevent the mistake of one signalman causing a collision of this kind would be by the adoption of one of the systems of interlocking the block instruments with the out-of-door signals in use upon a few lines in England. Another way which has been suggested would be by insulating a certain length of rails, as is done in places in America, and providing electrical arrangements which would lock the block instruments or the necessary signals so long as any axle were standing upon the insulated length of rails. This plan has not, however, been sufficiently experimented upon in this country to make it certain whether it is reliable, and if not reliable, it would be worse than useless.

**Serious Accident to Mr. Bernard Drake.**—Last week a temporary plant was fixed to supply the immediate requirements of the new Metropolitan Police buildings, the lighting of which was entrusted to Messrs. Drake and Gorham, and unfortunately one of the preliminary runs was attended by a serious accident to Mr. Bernard Drake. It seems that after visiting the different rooms in the premises he attempted to walk across the main courtyard of the building towards the engine-room, but unfortunately passed through an open door, immediately in front of which there was an unprotected area some 15ft. in depth. Instructions had been given that these doors were to be closed, and gas jets were provided in the area to prevent such an accident from occurring, but on this occasion the gas jets had been blown out and the doors had been left open by the painters. Mr. Drake was taken to the Westminster Hospital, which, it is hoped, he will be able to leave in about two months, unless other more serious symptoms should appear. We are glad to learn as we go to press that Mr. Drake is progressing favourably.

**Electricity in American Coal Mines.**—The introduction of electricity in the coal mines of Pennsylvania is, says the Pittsburg correspondent of the *Electrical Engineer* of New York, finding great opposition among the coal miners, who aver that the electric mining machines displace a number of men. The mine owners, however, do not pay much attention to this agitation, and mining machines are becoming more general every week. The mine owners state that the introduction of mining machines operated by electricity is the only means they have by which they can make their business pay. When the production of coal depended chiefly upon the miners, the cost of operating a mine was so large, and miners' wages were cut down so low, that no Americans could be induced to work at coal mining. In this emergency the advent of the mining machine was hailed with delight, and wherever mines are using electric power, the company not only can afford to pay its men good wages, but the business also makes a good profit.

**The Hazeltine Carbon Protector.**—In a recent issue the *Electrical World* describes an ingenious device intended to prevent the lateral waste of arc lamp carbons. The destruction of the carbon is partially due to actual waste at the point where the arc forms, and still more is produced by wasting around the sides of the poles where no proper return for the destruction is made in light received. The apparatus consists of a collar, made of fireclay or some similar refractory material, embracing the upper or positive carbon just above its point, and kept in the same position relative to the arc by an arrangement of chains. It shields the upper carbon so that the arc has no chance to disintegrate the carbon except at the immediate point where the arc is formed. The device has already been made use of by the Municipal Electric Lighting and Power Company of St. Louis, and the saving in the cost of carbons, trimming and caring for lamps is reported to be not less than 50 per cent. It is stated, too, that the effective candle-power of the lamp is increased.

**Bremen.**—According to the *Elektrotechnische Anzeiger*, the committee, consisting of Prof. Kittler, Director Salzenberg, and Herr Neukirch, report that Messrs. Siemens and Halske's

Digitized by Google

scheme for lighting the town of Bremen will involve a capital outlay of £100,000, and an annual expenditure of £4,500. This will provide for 10,000 16 candle-power glow-lamps in stalled, of which 8,000 could be run simultaneously, the mean time of burning of each lamp being 550 hours per annum. A second scheme, involving 25,000 lamps, 20,000 being run simultaneously, and the mean time of running each lamp being 500 hours per annum, is estimated to cost £135,000, with an annual expenditure of £8,500. A charge of 4·5 pfennings- (·54d.) per lamp-hour would, in the first project, bring in an annual profit of £7,875, or nearly 8 per cent. on the capital. Under the second plan, four pfennings (·48d.) per lamp-hour would bring in 12·2 per cent. on the capital outlay. The prices in various towns in Germany for a 16 candle-power lamp-hour are:—Barmen, ·48d.; Berlin, ·516d.; Darmstadt, ·48d.; Düsseldorf, ·54d.; Elberfeld, ·48d.; Hamburg, ·564d.; Königsberg, ·48d.; Lübeck, ·564d.; Mülhausen, ·48d.; Stettin, ·564d. It was recommended that £100,000 should be voted for the purpose of equipping an installation. A tender which has come to hand within the last few days from the Helios Company, of Cologne, has, however, delayed the adoption of this recommendation by the municipality.

**The Alkaline Accumulator.** — The alkaline accumulator devised by MM. Commelin, Desmazures, and Bailhache, full particulars of which are to be found in *The Electrician* of January 18, 1889, has recently undergone a small improvement in detail, which will tend to diminish the somewhat excessive loss of charge when left on open circuit, which was noticeable in the earlier types. A battery of these cells, weighing 21,650lb., is used on board the submarine boat, "Gymnote," and it has been found possible to obtain from this battery, without injury to it, no less than 345 horse-power hours, or one horse-power hour per 63lb. of dead weight. A battery of these cells was also employed to operate a Canet cannon during the Paris Exhibition last year. The Commelin-Desmazures accumulator contains, it will be remembered, compressed porous copper negatives (2 to 3 mm. thick), enclosed in an envelope of parchment cloth, and iron wire gauze positives, in a 50deg. Baumé solution of zincate of potassium. During the charge zinc is deposited upon the iron electrodes, and oxygen is absorbed by the copper electrodes. During the discharge the zinc is re-dissolved, combining again with the oxygen from the copper electrode. The average E.M.F. per cell is only ·75 volt. It was found that the parchment cloth became feebly conducting after long immersion in the electrolyte, and in consequence there was considerable loss of charge on open circuit. The cells are now constructed with the parchment cloth carefully insulated from the copper plates.

**Matthiessen's Correct Standard.**—The following is an abstract of the preliminary report of the "Standard Wiring Table" Committee of the American Institute of Electrical Engineers. After a very thorough investigation of Matthiessen's work, with a view to ascertaining what his standard really was, we consider, says the Committee, the correct Matthiessen's standard and the one in which he himself had most confidence was the "metre-gramme" standard. The Matthiessen's standard recommended is a hard-drawn copper wire one metre long, weighing one gramme ("metre-gramme") having resistance of ·1469 B. A. unit at temperature of 0°C.

*Table of Values based upon Matthiessen's Correct Standard.*

| — | B. A. Units. 0°C. | Legal ohms. 0°C. |
|---|---|---|
| Matthiessen's Standard metre gramme hard | ·1469 | ·1453 |
| Metre-gramme soft | ·1436 | ·1420 |
| Metre-millimetre hard | ·02104 | ·02080 |
| " " soft | ·02057 | ·02034 |
| Cubic centimetre hard | ·000001652 | ·000001634 |
| " " soft | ·000001616 | ·000001598 |
| Mil-foot hard | 9·940 | 9·829 |
| " soft | 9·9720 | 9·612 |

Specific resistance of hard copper (1 cub. cent.) = 1,634 C.-G.-S. units. Specific resistance of soft copper (1 cub. cent.) = 1,598 C.-G.-S, units, Matthiessen's standard specific gravity of hard copper, 8·89. Resistance of hard copper is 1·0226 times that of soft copper. Resistance of soft copper is ·9779 times that of hard copper. Legal ohm is equal to 1·0112 B. A. unit. B. A. unit is equal to ·9889 legal ohm.

**Paris.**—At a recent meeting of the Conseil Municipal two matters connected with the electrical supply companies were discussed at considerable length. The first discussion arose upon the report of the police authorities on the fire at the Grand Café. From this report it seems that the basement of the Grand Café had been converted into a battery transformer station, supplying 1,400 lights to customers in the vicinity. The report stated that the manager of the café asserted that the fire in question was at least the twentieth which had arisen from the same cause, and it concluded by attributing these mishaps to the ignition of the insulation of the leads due to excessive currents, the fuses not being properly proportioned to the carrying capacity of the leads. In the discussion which followed the reading of this report it came out that the charging current having a difference of potential of under 500 volts, nobody could interfere with such installations. It was resolved to petition the authorities to amend this regulation. The vexed question of the emission of smoke by the central stations was next debated. It was generally urged that the companies should be obliged to use coke or to consume their own smoke, and it was stated that a decree of 1854 enabled this demand to be enforced. Several members pointed out that no entirely satisfactory smoke annihilator existed, that the municipality was itself a very bad offender in this respect, that the 1854 decree had been superseded by a subsequent one. It was finally resolved to inaugurate a series of trials of smoke annihilators.—According to the *Bulletin International de l'Electricité*, the principal officials connected with the municipal station at the Halles Centrales are about to join the Compagnie Continentale Edison, and the station will, it is rumoured, be sold.

**The Central Lighting Station as an Investment.**—In a Paper on this aspect of electric lighting recently read before the Chicago Electric Club, Mr. B. E. Sunny refers to the various types of non-dividend paying central lighting stations. One type of non-dividend paying lighting station is, he remarks, the station that is well built, with good steam and electrical plant, and which starts off on its career with applause. It is a great success, and the patrons increase, until the fact is brought home to the owners that they have no more room left, and that they must add to the building. Then begins the work that ends in the central station becoming an exhibition of engineering gymnastics. Engines of various makes are crowded in spaces too small for them; high speed and low speed; big boilers and little ones, until the station takes on so many peculiarities that a change of engineers is apt to shut it down, until the new man can unravel the awful mystery. The remarkable thing about such a station is that it generally pays good dividends, for the reason that every boiler, engine, and dynamo is worked to its fullest capacity, and consequently under economical conditions. So long as the machinery stands the strain, the shareholders will have cause to rejoice. Re-building, however, means the throwing away of the old station in many instances; the selling off at a great sacrifice the smaller engines and boilers to make room for larger types. The stock representing the cost of the property abandoned continue, however, to be an obligation upon which dividends must be paid. Then during the transition period, while part of the work is being performed from the old station and part from the new, the increase in the operating expenses is very marked. It generally happens, too, that in their desire to make the new one a model station, the manager or superintendent devotes all his time and attention to *that* work, and leaves the old station to the boys to run, with the usual results. The whole secret of dividend-paying enterprises lies in their ability to run reliably, every day and every year, without subjecting the machinery to excessive and abnormal demands, and in the avoidance of rebuilding or abandoning original investments. Central stations, Mr. Sunny is of an opinion, should be planned from the commencement, with a view to meeting the growing demand, not of the next two years or so, but of the next fifteen or twenty years.

## ELECTRICAL DISTRIBUTION BY TRANSFORMERS FROM CENTRAL AND ECCENTRIC STATIONS.*

BY DR. J. A. FLEMING, M.A.

*(Continued from page 134.)*

*Systems of Distribution—Compensator System.*—This system of distribution for incandescent lighting by alternating currents is the invention of Prof. Elihu Thomson, and was introduced before the transformer system had attained much commercial expansion. The principle of the system is shown in Fig. 5.

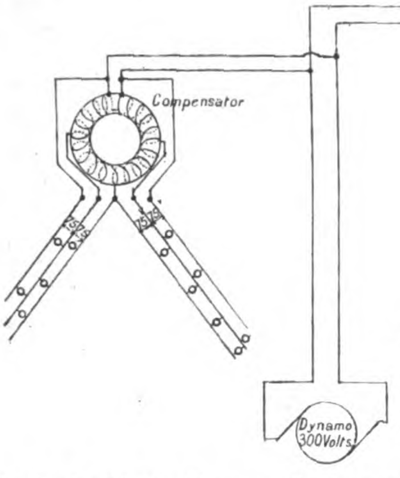

FIG. 5.—Prof. Elihu Thomson's "Compensator" System of Incandescent Lighting.

An alternating current generator usually wound for a potential of 330 volts delivers its current to the ordinary system of feeders and mains such as is employed in the direct two-wire system. At central points in the district to be lighted the compensators, or choking coils, are located—usually being placed upon poles at street intersections. A loss up to 10 per cent. of the dynamo potential, according to conditions, is allowed between the station and the lamps, and the pressure at the compensators is thus somewhat more than 300 volts.

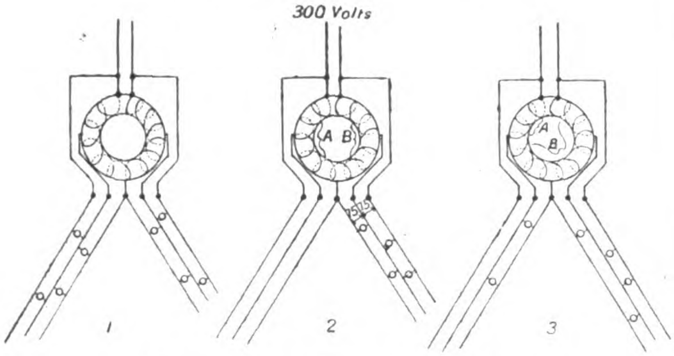

FIG. 6.—Three-wire Compensator System.

The compensator consists of a laminated core of iron as in a transformer, wound with a continuous insulated conductor, the terminals of which are connected directly to the dynamo leads.

At three points in this coil, dividing the coils equally between its terminals, wires are attached leading to binding posts on the compensator frame. The terminals of the coil are attached to similar binding posts, and from these five points are run lamp circuits, which may be two three-wire systems. The fall of potential through the compensator from one lead to the other will thus be divided into four equal parts, and the voltage in each lamp circuit will be, therefore, about 75 volts. It is evident that many variations may be made in this arrangement; the coil may be divided into any number of equal portions, and from them the circuits may be run on the 3, 4, 5, &c., wire-systems, or the various circuits may be on the simple two-wire system. We take, however, this 330 volt two 3-wire system to explain, as it was the one most used, and serves as well as any other to illustrate the principle of the arrangement.

Considering Fig. 6:—There are, at maximum load, say 8 lamps on the compensator; when they are all turned on, a very slight current traverses the coils of the compensators, the self-induction of its coils of wire wound about soft iron being so high as to practically prevent any current flow. Consider now that all the lamps on one of the three wire circuits be turned off, the conditions are as in sketch 2, Fig. 6.

The current traversing the part of the coil "A" acts as the primary of a transformer, the secondary being the part "B"; transformation from 150 volts in the primary to 150 volts in the secondary thus takes place, and one-half the current in the

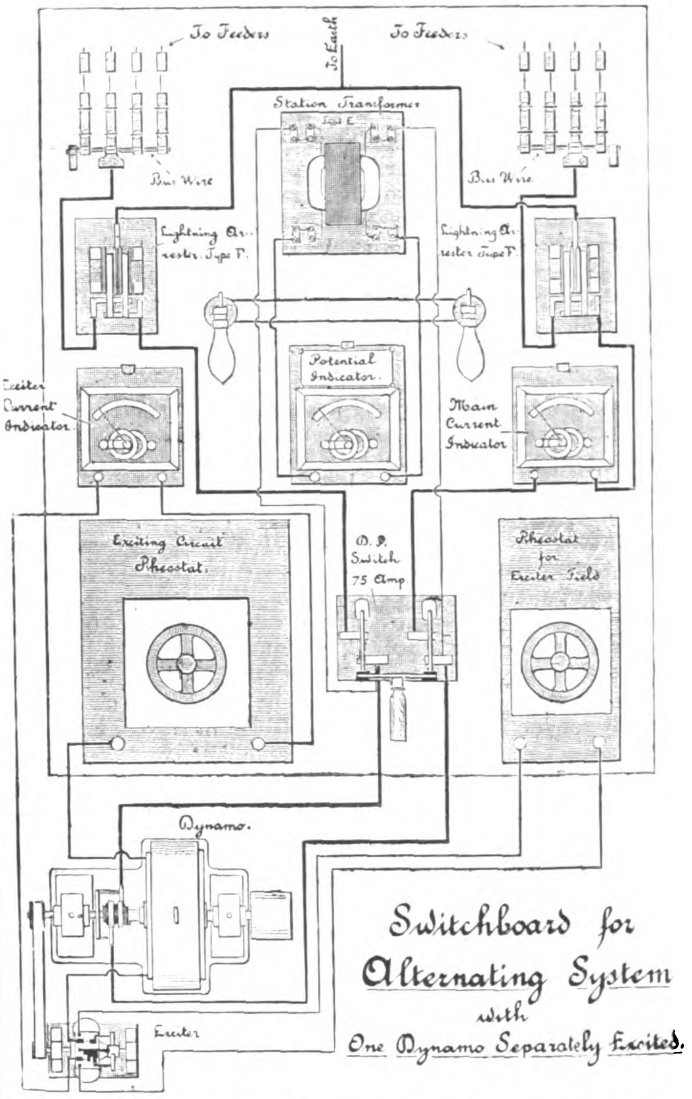

FIG. 7.—Switchboard for Thomson-Houston Transformer System.

lamp circuits is due to the dynamo current, and one-half to that part of the compensator marked "B." The part "A" thus needs to carry only sufficient current for one lamp, and the regulating capacity of the compensator is seen to be four times the carrying capacity of its wire. If the lamps be arranged as in sketch No. 3, the first part of the compensator marked "A" will carry $\frac{6}{4} = 1\frac{1}{2}$ times the current required for one lamp. The ratio of conversion in this case being 1 : 3, the part of the compensator marked "B" will supply $\frac{1 \cdot 5}{3} = \cdot 5$ times the current for one lamp.

In this way the action of the compensator for any arrangement of load may be readily deduced. In few words, its action is a combination of a transformer with a system of direct distribution.

* All rights are reserved.

Digitized by Google

The chief objection to this system is, of course, that it brings the high potential of the dynamo to the house wires.

The compensators have been manufactured in two sizes, one for 75 and the other for 150 lights. These figures, however, do not denote the maximum number of lamps which may be operated from a transformer, but merely the amount for which the compensator will regulate, *i.e.*, the maximum allowable difference in the number of lamps connected to its circuits.

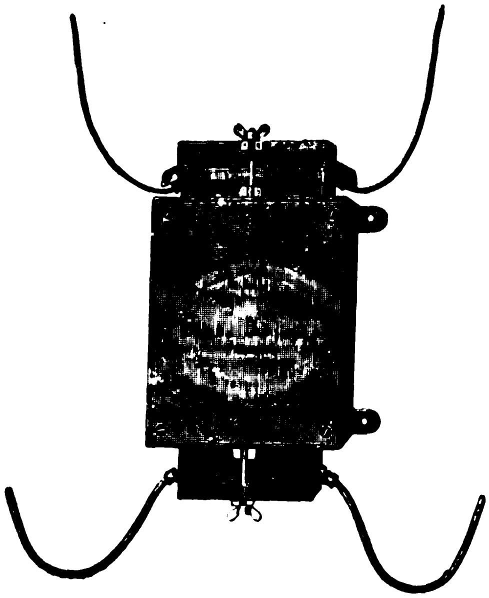

Fig. 8.—Thomson-Houston Transformer.

*Transformer System.*—The transformer system of the Thomson-Houston Electric Company is, like all other such successful systems, a constant potential one; the pressure employed being usually 1,000 volts. The dynamos are constructed to give 1,100, so that 10 per cent. may be allowed for loss in the primary and secondary circuits. As before stated, the dynamo is usually of the compound or "composite" type, the fields

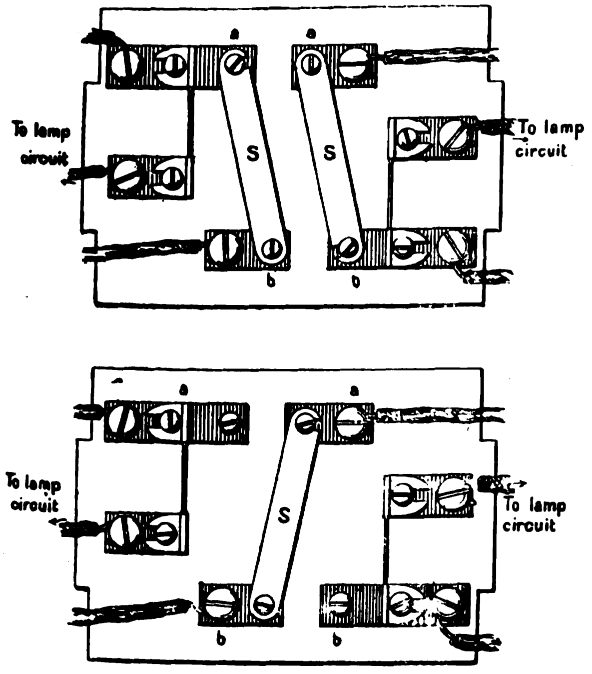

Fig. 9.—Connections on Thomson-Houston Transformer.

being excited by the rectified current from the alternator as well as by that from a small direct current dynamo.

In other respects this system is similar to other transformer systems and its principle needs no special explanation. Fig. 7 shows the form of switch-board employed. The various instruments which comprise it will be presently described. The dynamo has already been described. The standard type of alternator is the separately-excited drum armature alternator, compounded to give constant pressure for a drop of a definite number of volts in the primary line between no load and full load. This alternator is excellently designed in all its parts, and between full and no load can maintain constant potential at the end of its primary line.

*Transformers.*—The latest form of transformer manufactured by the Thomson-Houston Electric Company is shown in its box in perspective in Fig. 8. The coils are enclosed in a cast-iron box, waterproof, and stout enough to withstand ordinarily rough usage. The primary wires are seen coming out of the transformer at the top, and the secondary at the bottom, each passing through waterproof insulating bushings.

The coils are in some cases wound directly upon the cores, in others they are wound on wooden formers, which are removed when the coils are completed. In some forms the secondary winding is laid on first and the primary over it; in other forms the two are wound side by side. In either case the insulation between the two coils is very carefully made, consisting of mica, paper, and shellac. The secondary coil is wound with two equal circuits, which may be either connected in series to give 104 volts or connected in multiple arc to give 52. Fig. 9 shows the switch device by which these connections are made and the fuse wire terminals for holding the safety cut out for the secondary circuit.

*(To be continued.)*

## CAPACITY AND SELF-INDUCTION IN ALTERNATE CURRENT WORKING.—I.

BY GISBERT KAPP.

The peculiar interaction between capacity and self-induction of a circuit traversed by an alternating current has long been known to scientists, and as far back as 1884, Dr. Hopkinson gave in his Paper on "The Theory of Alternating Currents," read before the Society of Telegraph Engineers and Electricians, a practical example, in which he showed that with a certain capacity, periodic time, self-induction and resistance in circuit, the potential difference between the plates of the condenser may be 80 times the E.M.F. of the alternator. Startling as such a result must naturally appear, it failed at the time to attract much attention from practical engineers who, no doubt, pre-occupied with other problems relating to continuous-current work, were content to let such an intricate and apparently abstruse problem lie at rest until such time as its consideration should be forced upon them. This time has now come, and what in 1884 was merely an interesting laboratory experiment, having no further application than perhaps the breaking down of a condenser, is at present an intensely practical problem which the electrical engineer has to face. Phenomena arising from the effects of capacity in alternate-current circuits are forcing those who have to do with such circuits to give attention to the problems connected with these phenomena. As a case in point, I may mention that about a year ago I had to test a short underground line for a 2,000-volt alternating-current, and although the bridge test gave several hundred megohms with a steady E.M.F. of 300 volts, the line appeared to be leaky under an alternating E.M.F. of 2,000 volts. A Cardew voltmeter inserted between one of the terminals of the alternator and the corresponding main showed a small but unmistakable deflection, indicating the passage of a current. This was, of course, due to the fact that the line acted as a condenser, a small current flowing into and out of the line through the voltmeter. The capacity of the line was found to be ·037 of a microfarad, and to this corresponds at the pressure and frequency used a current of 45 milliamperes, a value quite high enough to give a slight deflection on the voltmeter. To neglect taking account of the capacity of the line would in such a case lead to a serious error in determining the insulation resistance in the manner described, whereas with a steady E.M.F. no such

Digitized by Google

error would be possible. Other problems of much more importance and on a much larger scale have since then cropped up, notably that which Mr. Ferranti has so successfully faced, of transmitting high-pressure currents from Deptford to London through a line which has considerable capacity. It is, therefore, not surprising that we find questions connected with such problems treated in the current literature.

An excellent article on the subject has been published by M. Boucherot a few weeks ago in *L'Electricien*. He considers there the following cases. (*a*) An alternate current circuit containing an inductionless resistance and a condenser placed in series; (*b*) such a circuit containing a resistance and a self-induction placed in series; and (*c*) such a circuit containing a resistance, a condenser, and a self-induction placed in series. In the latter case, he shows that with a very moderate E.M.F. impressed upon the circuit taken as a whole, the E.M.F. over the terminals of the self-induction coil and that between the plates of the condenser may, under certain circumstances, become almost infinite. The case investigated by M. Boucherot is, however, not the case we meet in practice. When the line is at work, that is to say, when more current than required to satisfy its electrostatic capacity is flowing through it, the condenser is not in series with, but forms a shunt to the lamps or whatever translating device is employed at the distant end. Under this condition M. Boucherot's solution does not apply, and I propose therefore in what follows to supplement his article by an investigation of the general case here mentioned.

Before entering into this subject it may perhaps be useful to state, for the benefit of the younger readers of *The Electrician*, what is the general aim of the investigation. The effect of self-induction and capacity combined is, broadly speaking, to produce somewhere in the circuit a pressure higher than intended, and it will easily be seen that where we already deal with high pressures such an increase may become a serious matter. It is therefore necessary to know what determines this increase of pressure, and how it can be kept within safe limits. Another effect due to the combined action of capacity and self-induction is an increase of current above the value which would suffice for working the lamps at the far end of the line if both self-induction and capacity were absent. It comes therefore to this, that if we design the alternator, whilst omitting to take account of the self-induction and capacity of the line, we shall find that we must work the machine at a lower E.M.F., and at a higher current than originally intended. Here let me draw the reader's attention to what I believe to be a popular error. An impression seems to be abroad that the effects of self-induction and capacity are only felt at one particular frequency, or, what comes to the same thing, at one particular speed of the alternator. It is supposed to be that speed at which the natural period of oscillation coincides with the period of the machine producing resonance between the machine and the circuit. This view was very clearly expressed in Mr. Swinburne's otherwise excellent Paper read at the last meeting of the Physical Society, when he said that a variation of 5 per cent. in the engine speed would at once destroy the interaction between self-induction and capacity—would in a word obviate all difficulties arising from these causes. I shall endeavour to show in this article that the difficulty exists at all speeds, but is either greater or smaller, accordingly as the speed is nearer to or farther away from that speed at which resonance obtains.

To facilitate the investigation it will be best to attack the problem piecemeal, taking first a circuit with resistance and self-induction, then a circuit with resistance and capacity, and finally a circuit having resistance, capacity, and self-induction. We assume that in all cases E.M.F. and current follow the sine law. We also assume that the coefficient of self-induction and the capacity are constants. The former assumption is not quite correct as far as relates to that part of the self-induction which is due to the armature of the alternator, since it depends to a certain extent on the relative position of the armature coils and field-magnet poles, which is constantly changing. It would, however, enormously complicate the investigation if we were to attempt to make a correction on this account, and the correction could in any case be but trifling. The second assumption regarding the constancy of the capacity would certainly be incorrect if we had to deal with an ordinary condenser consisting of tinfoil and paraffined paper. In such a condenser there is considerable electrostatic attraction between the coatings causing a compression of the paper, and consequently a diminution of distance between opposite coatings. The capacity must then increase with the potential difference on the terminals of the condenser, and cannot be a constant when, as with an alternating E.M.F. this pressure is continuously varying. When, however, the condenser takes the form of a concentric main of stout copper, or of two heavy cables drawn into a pipe, it is inconceivable that there should be any movement altering the relative position of the conductors, and we may, therefore, without error assume the capacity of such a main as constant.

The E.M.F. due to a self-induction L is

$$e = L\frac{di}{dt},$$

and since $i$ may be expressed as a simple sine function, such as $i = T \sin w t$, where $w = 2\pi\frac{1}{T}$, we can also write

$$e = L w I \cos w t.$$

This E.M.F. becomes a maximum at such times as the current passes through its zero value. Writing $E_s$ for this maximum value of the E.M.F. of self-induction, we find, therefore,

$$E_s = L w I.$$

In making measurements of current and E.M.F. we obtain, of course, not the maximum but the square root of mean squares, and it is, therefore, desirable to have a formula giving the effective value of E.M.F. Since the effective and maximum values, both as regards E.M.F. and current, are in the ratio of 1 to $\sqrt{2}$, it is obvious that the formula

$$E_s = L w I$$

will give the effective value of the E.M.F. if T be taken to represent the effective value of the current. The formula is based on C.-G.-S. units. If we wish to obtain $E_s$ in volts, we must divide the right side by $10^8$. If I is taken in amperes, we must further divide by 10, and if L is given in quadrants (or secohms) we must multiply by the ratio of the quadrant to the centimetre, namely, by $99,777 \times 10^4$. As, however, extreme accuracy is not of very great importance in treating problems, in which other and more important corrections must be neglected, we shall, for the sake of simplicity, assume that a quadrant is $100,000 \times 10^4$ centimetres, and must therefore multiply the right side of the equation by $10^9$. Hence, the equation as it stands is right for practical units, and we have

$$\left.\begin{array}{l}\text{Volts due to self-}\\ \text{induction.........}\end{array}\right\} = 2\pi \times \text{frequency} \times \text{quadrants} \times \text{amperes}$$

Thus to force a current of 10 amperes through a coil having a self-induction of ·1 quadrant with a frequency of 80 would require an E.M.F. of 500 volts.

Let the capacity of a condenser be C then an increment of E.M.F. of $d e$ will in the time $d t$ add to its charge the amount

$$C\, d e = i\, d t,$$

$i$ being the rate of current at which the additional charge $C\,de$ is supplied. Let $E_c$ be the maximum P D between the condenser plates, then $C E_c$ is the total charge, or the $\int i\, d t$ taken over a quarter period, that is, from $t = 0$ to $t = \frac{T}{4}$. Now $i\, d t = -\frac{1}{w} d(I \cos w t)$ and $C E_c = -\frac{1}{w}\left[I \cos w t\right]_{t=0}^{t=\frac{T}{4}}$ from which we obtain $I = w C E_c$.

Here, again, the values of current and E.M.F. may be taken to represent either the maxima or the effective values, whichever is more convenient. The above formula is given in C.-G.-S. units. If we want to have it in practical units we must remember that a microfarad is smaller than a C.-G.-S. unit of capacity in the ratio of $10^{15}:1$; that a volt is larger than a C.-G.-S. unit of E.M.F. in the ratio of $10^8:1$, and that an ampere is the tenth-part of a C.-G.-S. unit of current. We find thus the formula connecting capacity, volts and amperes as

$$I = C E_c w 10^{-6},$$

Digitized by Google

As an example, assume that we have a concentric cable of capacity $C=2$ microfarads, $E_c=10{,}000$ volts and $w=500$ ($n=80$) The current flowing in and out will be

$$I=2.\times 10{,}000\cdot 500\cdot 10^{-6}=10 \text{ amperes.}$$

Having thus established the fundamental relations between capacity, self-induction, current, and E.M.F., we can now proceed to show their practical application to problems of alternate current distributions, which shall be done in a subsequent article.

*(To be continued.)*

## DRUM ARMATURE WINDING.

BY F. M. WEYMOUTH.

*(Concluded from page 168.)*

A few more windings which we may touch on belong to an entirely distinct class, especially as regards their end connections. We refer to those in which the connections are made outside the circumference of the armature, instead of within. The first of these we may consider, is one patented by Messrs. Crompton and Kyle. This is based on the convolute principle, and consists of two series of convolutions running in opposite

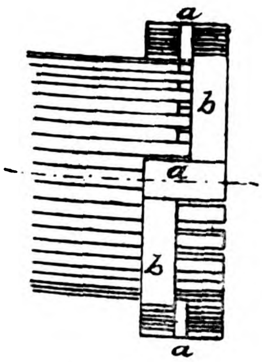

Fig. 45.—Crompton-Kyle Winding. Side View.

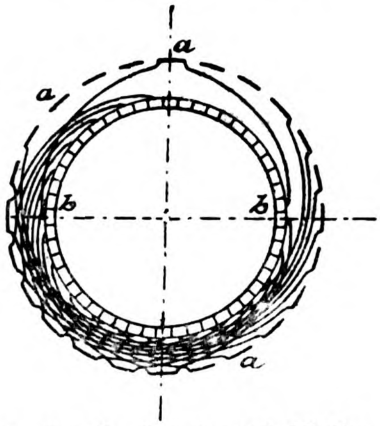

Fig. 46.—Crompton-Kyle Winding. End View.

directions outside the armature ends. Figs. 45 and 46 illustrate this arrangement, though with only a portion of the connectors shown. On the outer circumference will be observed jointing plates *a a a* parallel with the shaft. From each of these there spring two evolutes *b b* which proceed, one in each series of evolutes, to the opposing ends of a long and short bar respectively. One complete coupling *b a b* is thus shown apart in both views. Though cases may arise when this arrangement may be most suitable, yet in some respects it will not compare favourably with an inside end winding.

This form of winding plainly requires a longer coupling to unite the two ends of a diameter outside than inside the circumference. The joints, however, are all accessible after removing the commutator. But a disadvantage with this design results from the fact that an accumulation of material round the outer ends of the armature militates against the snugness of the machine as a whole. It is desirable to keep the "magnetic circuit" through the magnets as short as possible, and the field coils need to be brought close up to the pole-pieces to obtain their fullest effect. It will, therefore, be observed that designers generally bring the field coils as near the armature as possible, and, in fact, in the case of vertical machines, rest them on the horns, as shown at *a a*, Fig. 47. Thus the lines of magnetic induction generated in the magnets within the coils can pervade the pole-pieces with the least possible loss of strength, and the total magnetic resistance is kept to a minimum. In the design of end winding before us, however, the connectors would be in the way of the field coils, so that these would have to go further away from the armature, thus in some degree causing the advantage named to be sacrificed. This difficulty might, perhaps, be met by bending all the bars inward a little way toward the axis, as shown in Fig. 48. But bringing all the ends thus into a smaller circumference, unless the original spacing on the periphery of the core should be an open one, will tend to jamb them, and so necessitate their being formed to a deeper and narrower section, thereby introducing complications.

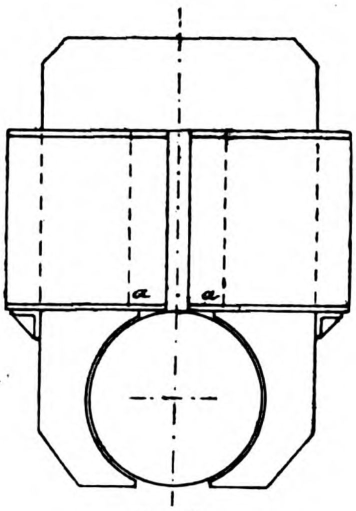

Fig. 47.

The next arrangement of outside end winding to which we may refer is one we believe was invented by a young employée formerly in the employ of Messrs. Latimer Clark, Muirhead and Co. This is shown somewhat diagrammatically in Fig. 49, and is in principle somewhat related to Siemens', Eickemeyer's, and Kapp's. With the two former it agrees in that each coil

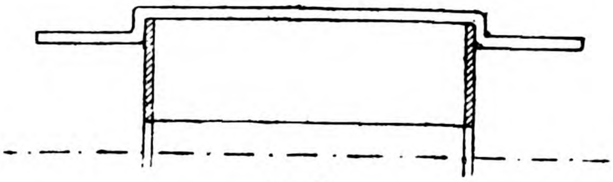

Fig. 48

consists of one wire, or group of wires, without joint from end to end; with the latter, in that the helical principle is introduced at the armature ends. Thus a coil starting, say, from a commutator lug at *a* pursues first a helical path through about a quarter circle to *b*, thence runs parallel to *c*, then down another helical path and approximate quarter circle to *d*, is here turned

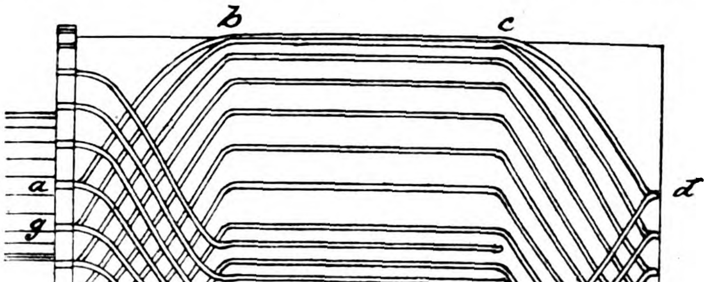

Fig. 49.—Diagram of a Suggested Form of Outside-end Winding.

back on itself, and pursues another helical path to *e*, and so on till it ends at another lug at *g*. It will be observed, however, in this winding, that the helices being in two layers, and all those from what correspond to the "long" bars crossing those from the "short" bars, the evil of the close proximity of conductors of maximum and minimum volts is in no wise

Digitized by Google

avoided; and the coils would need to be well insulated throughout. This form of winding is also neither economical in copper nor space, as compared with others that have been discussed. It is, however, well exposed to exterior ventilation; and to remove any burnt section, as in the case of the Eickemeyer arrangement, it would be necessary but to undo the connections with the commutator, and remove the exterior binding wires, to loosen the whole. It would, however, require some special cylindrical framing at the ends to carry the helical portions, the interior space of which would be more or less wasted. The armature also would be very long, necessitating a long machine.

If, however, we take this winding, and imagine all the parallel portion included within the letters *b*, *c*, *e*, *f* to be removed, so that *b f* coincides with *c e*, we shall then get approximately the last type of winding we propose to discuss, the Fritsche armature winding. The core of this armature is in fact, wound helically; the whole winding comes within the field, and it may be said that there is *no* "end winding." The pole-pieces are placed diagonally in this machine, with the corners cut off, in the manner indicated by the dotted lines in, Fig. 50. This, however, makes a bad field, as so large a proportion of the armature, as at *a a*, is uncovered by the pole-pieces; and the sectional area of the field, taken in a plane normal to its lines of force, is very much reduced compared to a field with the pole-pieces placed square in the usual manner. As regards facility for renewals, it is, of course, the same as the last described. On any armature, however, of a given diameter, it is not possible to put so many bars of a given size when laid

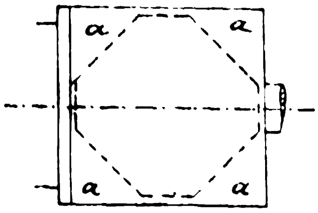

Fig. 50. - Fritsche Winding.

spirally as when laid in the ordinary manner parallel with the axis, comparing it, that is, with a parallel winding of two layers. Much care must obviously be involved in securing symmetry. An ulterior effect following on the diagonal arrangement of the pole-pieces to suit the helical winding is that, for any given output, the machine, as a whole, will need to be large and heavy as compared with others, and so will cost more. The coils, of course, have no joints, and, except those forming the inner layer, are well exposed to exterior ventilation. That the inner half should be without ventilation is a drawback. The commutator of this machine is abnormally large, as indicated. A full account of this machine was given in the *Electrician*, Vol. XXII., p. 655.

## THE ELECTRO-MAGNET.*

BY PROFESSOR SILVANUS P. THOMPSON.

(Concluded from page 18[illegible].)

### Polarised Mechanism: Uses of Permanent Magnets.

We must now turn our attention to one class of electro-magnetic mechanism which ought to be carefully distinguished from the rest. It is that class in which, in addition to the ordinary electro-magnet, a permanent magnet is employed. Such an arrangement is generally referred to as a polarised mechanism. The objects for which the permanent magnet is introduced into the mechanism appear to be in different cases quite different. I am not sure whether this is clearly recognised, or whether a clear distinction has ever been drawn between three entirely separate purposes in the use of a permanent magnet in combination with an electro-magnet. The first purpose is to secure unidirectionality of motion; the second is to increase the rapidity of action and of sensitiveness to small currents; the third to augment the mechanical action of the current.

(*a*.) [illegible] M[illegible].—In an ordinary electro-magnet it does not matter which way the current circulates; no matter whether the pole is north or south, the armature is pulled, and on reversing the current the armature is also pulled. There is a rather curious old experiment which Sturgeon and Henry showed, that if you have an electro-magnet with a big weight hanging on it, and you suddenly reverse the current, you reverse the magnetism, but it still holds the weight up; it does not drop. It has not time to drop before the magnet is charged up again with magnetic lines the other way on. Whichever way the magnetism traverses the ordinary soft iron electro-magnet, the armature is pulled. But if the armature is itself a permanent magnet of steel it will be pulled when the poles are of one sort, and pushed when the poles are reversed—that is to say, by employing *a polarised armature* you can secure unidirectionality of motion in correspondence with the current. One immediate application of this fact for telegraphic purposes is that of duplex telegraphy. You can send two messages at the same time and in the same direction to two different sets of instruments, one set having ordinary electro-magnets, with a spring behind the armature of soft iron, which will act simply independently of the direction of the current, depending only on its strength and duration; and another set having electro-magnets with polarised armatures, which will be affected not by the strength of the current, but by the direction of it. Accordingly, two completely different sets of message may be sent through that line in the same direction at the same time.

Another mode of constructing a polarised device is to attach the cores of the electro-magnet to a steel magnet, which imparts to them an initial magnetisation. Such initially-magnetised electro-magnets were used by Brett in 1848, and by Hjörth in 1850. A patent for a similar device was applied for in 1870 by Sir William Thomson, and refused by the Patent Office. In 1871 S. A. Varley patented an electro-magnet having a core of steel wires united at their ends.

Wheatstone used a polarised apparatus consisting of an electro-magnet acting on a magnetised needle. He patented, in fact, in 1845, the use of a needle permanently magnetised to be attracted one way or the other between the poles of an electro-magnet. Sturgeon had described the very same device in the *Annals of Electricity* in 1840. Gloesner claims to have invented the substitution of permanent magnets for mere armatures in 1842. In using polarised apparatus it is necessary to work, not with a simple current that is turned off and on, but with reversed-currents. Sending a current one way will make the moving part move in one direction; reversing the current makes it go over to the other side. The mechanism of that particular kind of electric bell that is used with magneto-electric calling apparatus furnishes an excellent example of a polarised construction. With these bells no battery is used; but there is a little alternate-current dynamo, worked by a crank. The alternate currents cause the pivotted armature in the bell to oscillate to right and left alternately, and so throw the little hammer to and fro between the two bells.

(*b*.) *Rapidity and Sensitiveness of Action.*—For relay work polarised relays are often employed, and have been for many years. Here on the table is one of the Post-office pattern of standard relay, having a steel magnet to give magnetism permanently to a little tongue or armature which moves between the poles of an electro-magnet that does the work of receiving the signals. In this particular case the tongue of polarised relay works between two stops, and the range of motion is made very small in order that the apparatus may respond to very small currents. At first sight it is not very apparent why putting a permanent magnet into a thing should make it any more sensitive. Why should permanent magnetism secure rapidity of working? Without knowing anything more, inventors will tell you that the presence of a permanent magnet increases the rapidity with which it will work. You might suppose that permanent magnetism is something to be avoided in the cores of your working electro-magnets, otherwise the armatures would remain stuck to the poles when once they had been attracted up. Residual magnetism would, indeed, hinder the working unless you have so arranged matters that it shall be actually helpful to you. Now for many years it was supposed that permanent magnetism in the electro-magnet was anything but a source of help. It was supposed to be an unmitigated nuisance, to be got rid of by all available means, until, in 1855, Hughes showed us how very advantageous it was to have permanent magnetism in the cores of the electro-magnet. Here (Fig. 51) is the drawing of Hughes's magnet to which I referred in Lecture III. A compound permanent magnet of horse-shoe shape is provided with coils on its pole-pieces, and there is a short armature on the top attached to a pivotted lever and a counteracting spring. The function of this arrangement is as follows. That spring is so set as to tend to detach the armature, but the permanent magnet has just enough magnetism to hold the armature on. You can, by screwing up a little screw behind the spring, adjust these two contending forces, so that they are in the nicest possible balance: the armature held on by the magnetism, and the spring just not able to pull it off. If, now, when these two actions are so nearly balanced you send an electric current round the coils of the electro

* A series of [illegible] Lectures delivered before the Society of Arts, January—February, 18[illegible]

Digitized by Google

current goes one way round, it just weakens the magnetism enough for the spring to gain the victory, and up goes the armature. This apparatus then acts by letting the armature off when the balance is upset by the electric current; and it is capable of responding to extremely small currents. Of course, the armature has to be put on again mechanically, and in Hughes's type-writing telegraph instruments it is put on mechanically between each signal and the next following one. The arrangement constitutes a distinctive piece of electro-magnetic mechanism.

(c.) *Augmenting Mechanical Action of Current.*—The third purpose of a permanent magnet to secure a greater mechanical action of the varying current is closely bound up with the preceding purpose of securing sensitiveness of action. It is for this purpose that it is used in telephone receivers; it increases the mechanical action of the current, and therefore makes the receiver more sensitive. For a long time this was not at all clear to me, indeed I made experiments to see how far it was due to any variation in the magnetic permeability of iron at different stages of magnetisation, for I found that this had something do do with it, but I was quite sure it was not all. Prof. George Forbes gave me the clue to the true explanation; it lies in the law of traction with which you are now familiar, that the pull between

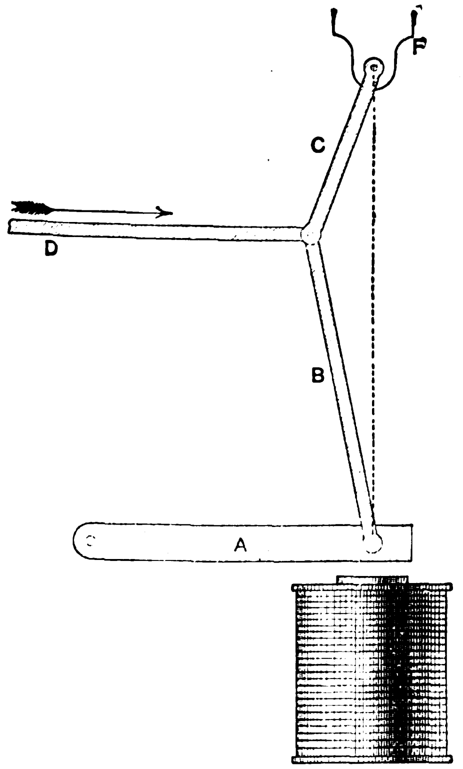

FIG. 68.—Froment's Equaliser with Stanhope Lever.

a magnet and its armature is proportional to the square of the number of magnetic lines that come into action. If we take N, the number of magnetic lines that are acting through a given area, then to the square of that the pull will be proportional. If we have a certain number of lines, N, coming permanently to the armature, the pull is proportional to $N^2$. Suppose the magnetism now to be altered—say made a little more; and the increment be called $dN$; so that the whole number is now $N + dN$. The pull will now be proportional to the square of that quantity. It is evident that the motion will be proportional to the difference between the former pull and the latter pull. So we will write out the square of $N + dN$, and the square of N, and take the difference.

Increased pull, proportional to $N^2 + 2N \cdot dN + dN^2$;
Initial pull, proportional to $N^2$;

Subtracting; difference is $2N \cdot dN + dN^2$.

We may neglect the last term, as it is small compared with the other. So we have, finally, that the change of pull is proportional to $2N \cdot dN$. The alteration of pull between the initial magnetism and the initial magnetism with the additional magnetism we have given to it, turns out to be proportional, not simply to the change of magnetism, but also to the initial number, N, that goes through it to begin with. The more powerful the pull to begin with, the greater is the change of pull when you produce a small change in the number of magnetic lines. That is why you have this greater sensitiveness of action when using Hughes's electro-magnets, and greater mechanical effect as the result of applying permanent magnetism to the electro-magnets of telephone receivers.

Here is another device for oblique approach, made by Froment. In the gap in the circuit of the magnet a sort of iron wedge is put in, which is not attracted squarely to either face, but comes in laterally between guides. Another of Froment's equalisers, or distributers, consists of a parallel motion attachment for the armature, so that oblique approach may take place, without actual contact. Here (Fig. 68) is another mechanical method of equalising devised by Froment, and used by Le Roux. You know the Stanhope lever, the object of which is to transform a weak force along a considerable range into a powerful force of short range. Here we use it backwards. The armature itself, which is attracted with a powerful force of short range, is attached to the lower end of the Stanhope lever, and the arm attached to the knee of the lever will deliver a distributed force over quite a different range. One way, not of equalising the actual motion over the range but of counterbalancing the variable attractive force, is to employ a spring instead of gravity to control the armature. So far back as 1838, Edward Davy, in one of his telegraphic patents, described the use of a spring (Fig. 69) to hold back the armature. Davy preceded Morse in the use of a spring to pull back the armature. There is a way of making a spring act against an armature more stiffly as the pull gets greater. In this method there is a spring with various set screws set up against it, and which come into action at different ranges, so as to alter the stiffness of the spring, making it virtually stiffer as the armature approaches the poles. Yet another method

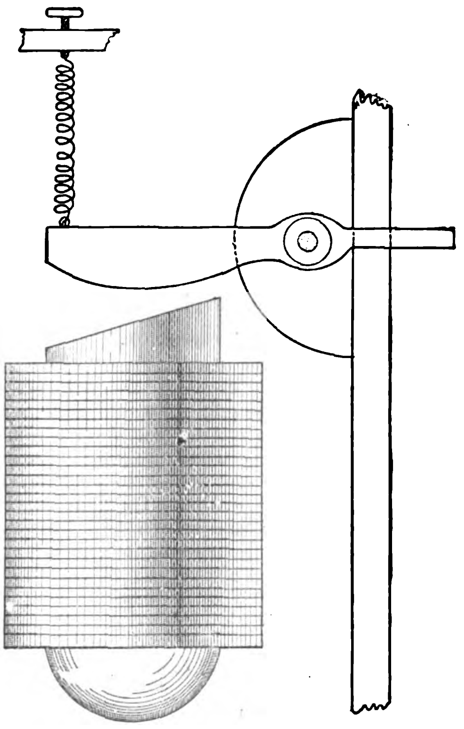

FIG. 69.—Davy's Mode of Controlling Armature by Spring

is to employ, as the famous conjuror Robert Houdin did, a rocking lever. Fig. 70 depicts one of Robert Houdin's equilisers. The pull of the electro-magnet on the armature acts on a curved lever which works against a second one; the point of application of force between the one and the other altering with their position. When the armature is far away from the pole, the leverage of the first lever on the second lever is great. When the armature gets near, the leverage of the first lever on the second is comparatively small. This employment of the *rocking lever* was adopted from Houdin by Duboscq, and put into the Duboscq arc lamp, where the regulating mechanism at the bottom of the lamp contains a rocking lever. Here upon the lecture table is a Duboscq's arc lamp. In this pattern (Fig. 71), one lever, B, which is curved, plays against another, A, which is straight. A similar mechanism is used for equalising the action in the Serrin arc lamp, where one of the springs that holds up the jointed parallellogram frame is applied at the end of a rocking lever to equalise the pull of the regulating electro-magnet. In this lamp there is also introduced the principle of oblique approach, for the armature of the electro-magnet is not allowed to travel straight towards the poles of the magnet, but is pulled up obliquely past it.

Another device for equalising the pull was used by Wheatstone in his step-by-step telegraph in 1840. A hole is pierced in the armature, and the end of the core is formed into a projecting cone which passes through the aperture of the armature, thereby securing a more equable force and a longer range. The same device has reappeared in recent years in the form of electro-magnet used in the Thomson-Houston arc lamp, and in the automatic regulator of the same firm.

### Electro-magnetic Mechanism.

There are some other kinds of electro-magnetic mechanism to which I must briefly invite your attention, as forming an important part of this great subject. Of one of these the mention of permanent magnets reminds me.

### Moving Coil in Permanent Magnetic Field.

A coil traversed by an electric current experiences mechanical forces if it lies in a magnetic field; the force being proportional to the intensity of the field. Of this principle the mechanism of Sir W. Thomson's siphon recorder is a well-known example. Also those galvanometers which have for their essential part a movable coil suspended between the poles of a permanent magnet, of which the earliest example is that of Robertson (see *Encyclopædia Britannica*, Ed. VIII., 1855), and of which Maxwell's suggestion,

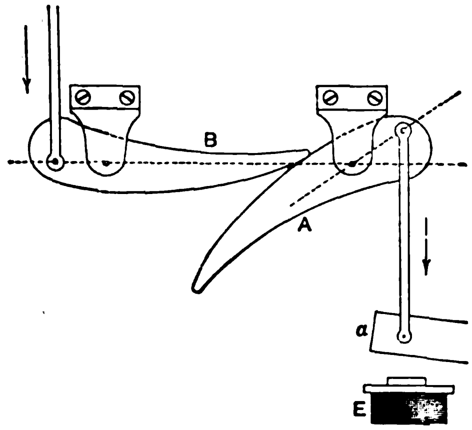

Fig. 70.—Robert Houdin's Equaliser.

afterwards realised by d'Arsonval, is the most modern. Siemens has constructed a relay on a similar plan.

### Magnetic Adherence.

There are a few curious pieces of apparatus devised for increasing adherence electro-magnetically between two things. Here is an old device of Nicklès, who thought he would make a new kind of rolling gear. Whether it was a railway wheel on a line, or whether it was going to be an ordinary wheel gearing, communication of motion was to be made from one wheel to another, not by cogs or by the mere adherence of ordinary friction, but by magnetic adherence. In Fig. 72 there are shown two iron wheels rolling on one another, with a sort of electro-magnetic jacket around them, consisting of an electric current circulating in a coil, and causing them to attract one another, and stick together with magnetic adherence. In Nicklès' little book on the subject there are a great number of devices of this kind described, including a magnetic brake for braking railway waggons, engines, and carriages, apply-

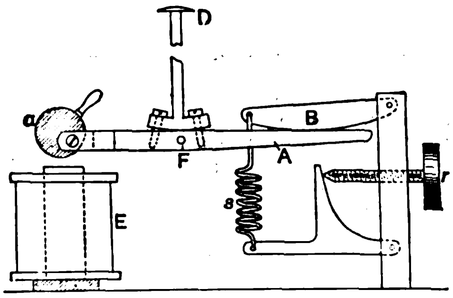

Fig. 71.—Mechanism of Duboscq's Arc Lamp.

ing electro-magnets either to the wheels or else to the line, to stop the motion whenever desired. The notion of using an electro-magnetic brake has been revived quite recently in a much better form by Prof. G. Forbes and Mr. Timmis, whose particular form of electro-magnets, shown in Fig. 73, is peculiarly interesting, being a better design than any I have ever seen for securing powerful magnetic traction for a given weight of iron and copper. The magnet is a peculiar one; it is represented here as cut away to show the internal construction. There is a sort of horseshoe made of one grooved rim, the whole circle of coil being laid embedded in the groove. The armature is a ring which is attracted down all round, so that you have an extremely compact magnetic circuit around the copper wire at every point. The magnet part is attached to the frame of the waggon or carriage, and the ring-armature is attached to the wheel or to its axis. On switching on the electric current the rim is powerfully pulled, and braked against the polar surface of the electro-magnet.

Forbes's arrangement appears to be certainly the best yet thought of for applying a magnetic brake to the wheels of a railway train.

Another, but quite distinct, piece of mechanism depending on electro-magnetic adherence is the magnetic *clutch* employed in Gülcher's arc lamp.

### Repulsion Mechanism.

Then there are a few pieces of mechanism which depend on repulsion. In 1850 a little device was patented by Brown and Williams, consisting, as shown in Fig. 74, of an electro-magnet which repelled part of itself. The coil is simply wound on a hollow tube, and inside the coil is a piece, B, of iron, bent as the segment of a cylinder to fit in, going from one end to the other. Another

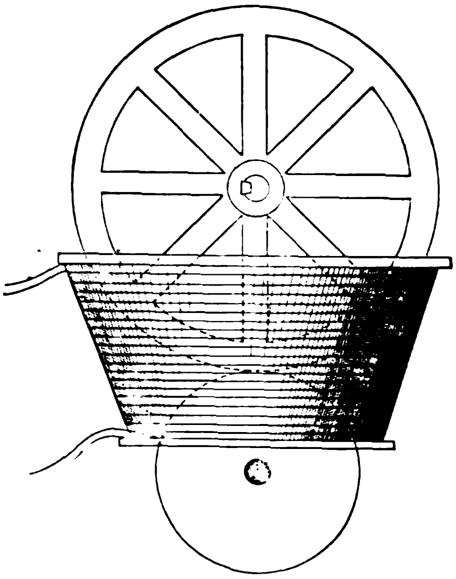

Fig. 72.—Nicklès' Magnetic Friction-Gear.

little iron piece, A, also shaped as the segment of a tube, is pivotted in the axis of the coil. When these are magnetised one tends to move away from the other, they being both of the same polarity. Of late there have been many ampere-meters and voltmeters made on this plan of producing repulsion between the parallel cores.

Here (Fig. 75) is another device of recent date, due to Maikoff and De Kabath. Two cores of iron not quite parallel, pivotted at the bottom, pass up through a tubular coil. When both are magnetised, instead of attracting one another, they open out; they tend to set themselves along the magnetic lines through that tube. The cores being wide open at the bottom tend to open also at the top.

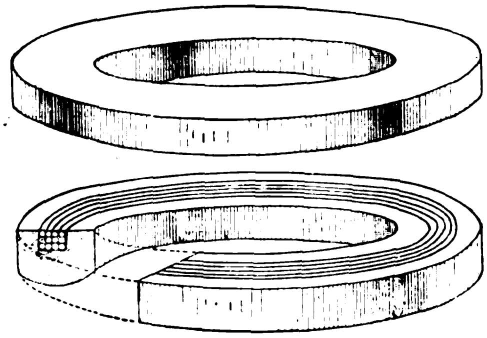

Fig. 73.—Forbes's Electro-Magnet.

### Electro-magnetic Vibrators.

Then there is a large class of mechanisms about which a whole chapter might be written, namely, those in which vibration is maintained electro-magnetically. The armature of an electro-magnet is caused to approach and recede alternately with a vibrating motion, the current being automatically cut off and turned on again by a self-acting brake. The electro-magnetic vibrator is one of the cleverest things ever devised. The first vibrating electro-magnetic mechanism ever made was exhibited here in this room in 1824 by its inventor, an Englishman named James Marsh. It consisted of a pendulum vibrating automatically between the poles of a permanent magnet. Later, a number of other vibrating devices were produced by Wagner, Neef, Froment, and others. Most important of all is the mechanism of the common electric trembling bell, invented by a man whose very name appears to be quite forgotten—John Mirand. How many of the millions of people who use electric bells know the name of the man who invented them? John Mirand, in the year 1850, put the electric

Digitized by Google

bell practically into the same form in which it has been employed from that day to this. The vibrating hammer; the similar push-button; the indicator or annunciator, are all of his devising, and may be seen depicted in the specification of his British patent just as they came from his hand.

Time alone precludes me from dealing minutely with these vibrators, and particularly with the recent work of Mercadier and that of Langdon-Davies, whose researches have put a new aspect on the possibilities of harmonic telegraphy. Langdon-Davies's rate-governor is the most recent and perfect form of electro-magnetic vibrator.

### Indicator Movements.

Upon the table here are a number of patterns of electric bells, and a number also of the electro-mechanical movements or devices employed in electric bell work, some of which form admirable illustrations of the various principles that I have been laying down. Here is an iron-clad electro-magnet; here a tripolar magnet; here a series of pendulum motions of various kinds; here is an example of oblique pull; here is Jensen's indicator, with lateral pull; here is Moseley's indicator, with a coil and plunger, iron-clad; here is a clever device in which a disc is drawn up to better the magnetic circuit. Here, again, is Thorpe's semaphore indicator, one of the neatest little pieces of apparatus, with a single central core surrounded by a coil, while a little strip of iron coming round from behind serves to complete the circuit all save a little gap. Over the gap stands that which is to be attracted, a flat disc of iron, which, when it is attracted, unlatches another disc of brass which forthwith falls down. It is an extremely effective, effective, very sensitive, and very inexpensive form of annunciator. The next two are pieces of polarised mechanism having a motion directed to one side or the other, according to the direction of the current. From the back-board projects a small straight electro-magnet. Over it is pivotted a small arched steel magnet, permanently magnetised, to which is attached a small signal lever bearing a red disc. If there is a current flowing one way, then the magnet that straddles over the pole of the electro-magnet

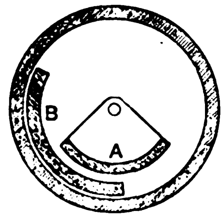

Fig. 74.—Electro-magnetic Mechanism Working by Repulsion.

will be drawn over in one direction. If I now reverse the current, the electro-magnet attracts the other pole of the curved magnet. Hence this mechanism allows of an electrical replacement, without compelling the attendant to walk up to the indicator board. The polarised apparatus for indicators has this advantage, that you can have electrical as distinguished from mechanical replacement.

### The Study of Electro-magnetic Mechanism.

The rapid survey of electro-magnetic mechanisms in general has necessarily been very hurried and imperfect. The study of it is just as important to the electrical engineer as is the study of mechanical mechanism to the mechanical engineer. Incomplete as is the present treatment of the subject, it may sufficiently indicate to other workers useful lines of progress, and so fitly be appended to these lectures on the electro-magnet. In a very few years we may expect the introduction into all large engineering shops of *electro-magnetic tools*. On a small scale, for driving dental appliances, electro-magnetic engines have long been used. Large machine tools, electro-magnetically worked, have already begun to make their appearance. Some such were shown at the Crystal Palace, in 1881, by Mr. Latimer Clark; and more recently, Mr. Rowan, of Glasgow, has devised a number of more developed forms of electro-magnetic tools.

### Suppression of Sparking.

It now remains for me to speak briefly of the suppression of sparks. There are some half-dozen different ways of trying to get rid of the sparking that occurs in the breaking of an electric circuit whenever there are electro-magnets in that circuit. Many attempts have been made to try and get rid of this evil. For instance, one inventor employs an air blast to blow out the spark just at the moment it occurs. Another causes the spark to occur under a liquid. Another wipes it out with a brush of asbestos cloth that comes immediately behind the wire and rubs out the spark. Another puts on a condenser to try and store up the energy. Another tries to put on a long thin wire or a high resistance of liquid, or something of that kind, to provide an alternate path for the spark, instead of jumping across the air and burning the contacts. There exist some half-score, at any rate, of that kind of device. But there are devices that I have thought it worth while to examine and experiment upon, because they depend merely upon the mode of construction adopted in the building of the electro-magnet, and they have each their own qualities. I have here five straight electro-magnets, all wound on bobbins the same size, for which we shall use the same iron core and the same current for all. They are all made, not only with bobbins of the same size, but their coils consist as nearly as possible of the same weight of wire. The first one is wound in the ordinary way; the second one has a sheath of copper wound round the interior of the bobbin before any wire is put on. This was a device, I believe, of the late Mr. C. F. Varley, and is also used in the field magnets of Brush dynamos. The function of the copper sheath is to allow induced currents to occur, which will retard the fall of magnetism, and damp down the tendency to spark. The third one is an attempt to carry out that principle still further. This is due to an American of the name of Paine, and has been revived of late years by Dr. Aron, of Berlin. After winding each layer of the coil, a sheath of metal foil is interposed so as to kill the induction from layer to layer. The fourth one is the best device hitherto used, namely, that of differential winding, having two coils connected so that the current goes opposite ways. When equal currents flow in both circuits there is no magnetism. If you break the circuit of either of the two wires the core at once becomes magnetised. You get magnetism on breaking, you destroy magnetism on making the circuit; it is just the inverse case to that of the ordinary electro-magnet. There the spark occurs when magnetism disappears, but here, since the magnetism disappears when you make the circuit, you do not get any spark at make, because the circuit is already made. You do not get any at break, because at break there is no magnetism. The fifth and last of these electro-magnets is wound according to a plan devised by Mr. Langdon-Davies, to which I alluded in the middle of this lecture, the bobbin being wound with a number of

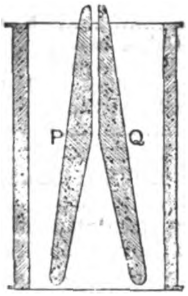

Fig. 75.—Repulsion between two Parallel Cores.

separate coils in parallel with one another, each layer being a separate wire, the separate ends of all the layers being finally joined up. In this case there are fifteen separate circuits; the time-constants of them are different, because, owing to the fact that these coils are of different diameters, the coefficient of self-induction of the outer layers is rather less, and their resistance, because of the larger size, rather greater than those of the inner layers. The result is that instead of the extra currents running out all at the same time, it runs out at different times for these fifteen coils. The total electromotive force of self-induction never rises so high, and it is unable to jump a large air-gap, or give the same bright spark as the ordinary electro-magnet would give. We will now experiment with these coils. The differential winding gives absolutely no spark at all, and second in merit comes No. 5, with the multiple-wire winding. Third in merit comes the coil with intervening layers of foil. The fourth is that with copper sheath. Last of all, the electro-magnet with ordinary winding.

### Conclusion.

Now let me conclude by returning to my starting point—the invention of the electro-magnet by William Sturgeon. Naturally you would be glad to see the counterfeit presentment of the features of so remarkable a man, of one so worthy to be remembered amongst distinguished electricians and great inventors. Your disappointment cannot be greater than mine when I tell you that all my efforts to procure a portrait of the deceased inventor have been unavailing. Only this I have been able to learn as the result of numerous inquiries: that an oil painting of him existed a few years ago in the possession of his only daughter, then resident in Manchester, whose address is now, unfortunately, unknown. But if his face must remain unknown to us, we shall none the less proudly concur in honouring the memory of one whose presence once honoured this hall wherein we are met, and whose work has won for him an imperishable name.

---

Prof. Thompson, in replying to the vote of thanks, stated that if any of those present could assist him in discovering what had become of the portrait of William Sturgeon, or in gleaning any particulars with regard to John Mirand, he should be much indebted to them if they would communicate with him.

# The Electrician.

ublished every Friday, Price Fourpence; Post Free, Fourpence Halfpenny.
Editorial, Publishing, and Printing Offices:
SALISBURY COURT, FLEET ST., LONDON, E.C.
*Telephone No. 2714. Telegrams:* "ELECTRICIAN NEWSPAPER, LONDON."

*All Letters relating to Subscriptions, Advertisements and other business matters should be addressed to the Publisher, "*THE ELECTRICIAN,*" Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to "*THE ELECTRICIAN*" Printing and Publishing Company, Limited, and be crossed "Coutts and Co." All other letters to be addressed to the Editor.*

*All letters intended for insertion in "*THE ELECTRICIAN,*" or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever will be taken of anonymous communications.*

"THE ELECTRICIAN" *is published every Friday morning, in time for the morning mails. Subscribers should receive their copies by the first post on Friday morning.*

"THE ELECTRICIAN" *is on sale at the railway bookstalls throughout the Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices as above.*

*New Volumes of* "THE ELECTRICIAN" *commence in May and November.*

## SUBSCRIPTION RATES.

The rates for Subscriptions to "THE ELECTRICIAN" are as follows :—

| | 3 months. s. d. | 6 months. s. d. | 12 months. s. d. |
|---|---|---|---|
| For the United Kingdom | 5 0 | 10 0 | 19 6 |
| For Foreign Parts and Colonies:— Within Postal Union | 6 6 | 12 6 | 24 0 |
| Aden Borneo, Ceylon, China, India, Japan, Java, Labuan, Mozambique, New Caledonia, Persia, Philippine Islands, Siam, Transvaal, and Zanzibar | 7 6 | 14 6 | 28 0 |

## TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has by far the largest circulation of any English Electrical paper, and circulates all over the World.**

*Particulars relating to Advertisements will be promptly forwarded on application to the Offices as above.*

TRADE ADVERTISEMENTS *intended for the current issue must reach the Offices not later than First Post on Thursday morning. Renewals of expiring advertisement orders and alterations to standing advertisements should be in the Publisher's hands by Wednesday at latest. No alteration can be made in Wrapper advertisements after Wednesday evening.*

SMALL PREPAID ADVERTISEMENTS *(for Rates see page xvii.) are accepted up to 4 p.m. on Thursday.*

## TECHNICAL PRINTING.

"THE ELECTRICIAN" PRINTING AND PUBLISHING COMPANY (LIMITED) *inform Electricians, Electric Light Engineers, &c., that they make a specialty of Technical Printing, and have a large Staff thoroughly acquainted with Electro-Technology. They can, therefore, promise Accuracy and Despatch in the Printing of Electro-Technical Literature, &c.*

## "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. (Royal 8vo.)

*Early in each year is issued* "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. *The* DIRECTORY *was established in 1883, and the 1890 Edition consisted of about 850 pages of printed matter. The names and addresses of all persons engaged in the Electrical Industries at home and abroad may be relied upon as accurate. Useful Tables and Electrical Formulæ, and information specially compiled for this work are given, together with popularly-written Biographical Notices of the leading Electricians, Electrical Engineers, &c., accompanied in many cases by Portraits.*

*Orders for the 1890 issue should be forwarded* AT ONCE *to the Publishing Offices, Salisbury-court, Fleet-street, London, E.C.*

*The 1891 Edition is now preparing, and New Names, &c., can now be received.*

## ELECTRICAL BOOKS AND PUBLICATIONS.

***All Books, Newspapers, and other publications, dealing with Electrical and kindred subjects, can be ordered direct of*** **"THE ELECTRICIAN"** ***Printing and Publishing Company, who are proprietors of the well-known*** **"ELECTRICIAN"** ***Series of Standard Electrical Works, and are agents for all the leading publishing houses at home and abroad.***

## THE FERRANTI EFFECT.

The discussions at the Physical Society frequently exhibit a little inertia. At meetings the President invites member after member, in vain, to offer remarks; and the author is permitted to place his own interpretation on the silence. His Paper is either so complete that nothing more can be said, and so accurate that no criticism can be raised, or its cool reception may be due to another reason, on which it is unnecessary to dwell. But occasionally the other kind of inertia is manifest, and the subject is tossed from one speaker to another until it is split into fragments, each of which is seized on by a different member, and the game is kept up with growing complication until long after the hour at which an afternoon meeting can be expected to continue, and, indeed, sometimes until the Paper itself has been well nigh forgotten. Although something of this kind took place last Friday, the most interesting Paper of Mr. SWINBURNE is not one which it is easy to forget.

Beginning with the discussion on condensers, the subject of non-homogeneous dielectrics was touched upon. This led to the brown paper of the Ferranti mains. Returning to condensers, Mr. BLAKESLEY described a split dynamometer method of measuring the power absorbed in an alternate current circuit, then quartz and various kinds of glass were discussed, a little confusion being caused by some members speaking of its resistance, others of its inductance. Then the soakage of the charge into a Leyden jar came up, and Sir WILLIAM THOMSON gave some interesting information about the instantaneous discharge of a jar by a rebounding metal ball. This led to Hertz's work on the duration of contact of colliding bodies, and it was

Digitized by Google

mentioned that two globes of steel, each the size of the earth, colliding together after approaching with a velocity of one centimetre per second would remain in contact for 27 hours. After this the meeting returned to Leyden jars, and thence to the insulation of armature coils, and to the thermal considerations of imperfect dielectrics. Then, with an "impulsive rush," the meeting went back to the increase of volts on the FERRANTI mains. Mr. SWINBURNE had practically stated that the alleged results were impossible, and that resonance could have nothing to do with it, and proceeded to offer an explanation of something which might have happened. Sir WILLIAM THOMSON gave some calculations founded on one assumed capacity, Mr. SWINBURNE taking another value, both being not far from, but on opposite sides of the true figure. Then Prof. AYRTON gave an account of what he had heard from Mr. FERRANTI, and Mr. KAPP described some experiments of his own, in which he had measured the volts by the length of the disruptive discharge. Another speaker ventured to contribute some information obtained from the inventor of the mains in question. Amid the confusion of theories and conflict of evidence, Mr. SWINBURNE pleaded that he had received his account from Mr. SPARKS, who, in the opinion of one of the most distinguished members present, should be considered as the highest authority on disruptive discharges.

A great deal of the confusion appeared to spring from the fact that the rise in volts is due to the length of the main—the longer the main the higher the volts; but yet the voltage of the main itself is practically uniform, except for the ordinary drop due to its ohmic resistance. The facts may be very simply stated, and we have the authority of Mr. FERRANTI for the accuracy of the following:—When the mains were being laid the insulation of the outer conductor was tested by the application of a pressure of 500 volts from a converter. In order to be quite sure that the pressure was on the mains, five lamps of 100 volts each were lighted on the far end. It was found as the length of main was increased that the brightness of the lamps also increased; and it was further found a little later on that another lamp had to be put in series in order that the lamps lighted across the ends should not be too bright. This effect was not altogether new to Mr. FERRANTI, as he had found practically the same thing some 18 months or two years ago when testing cables; but extreme pressure put upon him by the large quantity of work in hand, prevented his giving it that amount of attention and consideration which so interesting a phenomenon deserved. Nothing whatever happened to the dynamo, as ingeniously supposed by Mr. SWINBURNE, nor was it necessary to connect a transformer at the distant end, although, when it is done the effect is substantially the same. This heaping up of the voltage at the distant end of the line has been investigated by several mathematicians, and as we believe that it will shortly be thoroughly dealt with by far more able hands, we do not propose to go into any theoretical considerations on the present occasion. The phenomena of resonance are of two kinds, one of which has little or nothing to do with the question. Resonance is the result of a coincidence between the period of the alternate current and the natural period of oscillatory discharge of the condenser. The wave length of the Deptford current is some two thousand miles. If there be a harmonic corresponding to the eighth octave above, it might be commensurable with the length of the main, but no true resonance could arise on this account. As Mr. SWINBURNE observed when he demolished his own hypothesis of resonance, any effect of this kind must be dependent on the frequency of the alternations, and we believe that the explanation will resolve itself into a simple question of capacity and self-induction, and has not been observed before simply because the capacity has never reached so high a value on any previous conductor in which considerable alternating currents have been carried. It should be remarked that the rise in the voltage or the altered ratio of transformation does not, as has been asserted, disappear when a considerable current is passing. It has been observed when 250 horse-power was being transmitted, that the volts at Deptford were apparently 8,500, while 10,000 were found at London, nearly eight miles distant. No sooner was this discovered than it was found that no such "heaping up" is observed when the mains are supplied direct by a dynamo, so no inconvenience whatever will be felt by the London Electric Supply Company in practice.

It would seem that a difficulty will be thus placed in the way of those who have proposed to use "step up" transformers and low-pressure dynamos, thus avoiding the difficulties and dangers of high volts; and it may be that some dynamos which have high-self induction may exhibit this effect when coupled direct on to a circuit of considerable capacity. The matter will not long remain in obscurity. Mr. KAPP has set to work without delay, and the first part of his contribution upon this question will be found in another column. Prof. AYRTON promises to deal with it in a paper before the Physical Society. Dr. FLEMING has had the calculations in hand for some time past, and the author of the "Ferranti effect" is by no means leaving others to explain the strange experiment which he has conducted on so gigantic a scale.

## REVIEWS.

**Spinning Tops.** By Prof. J. Perry, F.R.S. Romance of Science Series. Society for Promoting Christian Knowledge. (London: 1890.)

This admirable little book, which has but little to do with electricity, is based upon the lecture delivered at Leeds during the last meeting of the British Association. The latter portion, it is true, contains some very interesting suggestions with regard to magnetic theories, but if they were absent we should not think it necessary to make excuse for noticing it in these columns. As a book on mechanics, it is sufficient to say that it is as clear, as original, as interesting, and as valuable as the "Practical Mechanics" of the same author. We have on several occasions imagined that we grasped the explanation of the behaviour of a gyroscope, and we must confess that on each occasion we failed to retain any tolerable conception of it for more than about twenty minutes. But no one who carefully reads and follows the arguments of this little work, aided by the excellent illustrations, can fail to gain either a thorough insight into the strange stiffness and obstinate crab-like tricks of a gyroscope, or, at all events, a tolerably clear idea of what it really tries to do, the laws which it may be said to obey, and a general knowledge of the many accompanying phenomena of top spinning, such as precession, nutation, and "going to sleep."

Some years ago we spent no little time in endeavouring to arrive at a common-sense explanation of gyroscopic action, and we searched authorities of every kind. The only writers who had anything whatever to say about it were those kind of mathematicians who address themselves to others of their own attainments, and who seem to think that to reduce their language a little nearer to the comprehension of less learned people is to lower the dignity of their subject, if not of themselves. Fortunately, Prof. Perry not only continually keeps in mind that he is addressing himself to a popular audience, but he has very decided ideas as to how much he shall put before them, how much must only be briefly alluded to, what expressions may be used without going into explanation of their precise meaning, and what ideas it is absolutely necessary to clearly define and understand. To read the book through from beginning to end, as we have done, is to

Digitized by Google

do very little with it. We are looking forward to repeating many of his experiments with his book in hand, and learning thoroughly those many features of the top and the gyroscope, which mathematicians merely use as pegs on which to hang their frightful festoons of mixed mathematics.

**Soap Bubbles, and the Forces which Mould them.** By C. V. Boys, F.R.S. (Society for the Promotion of Christian Knowledge, London, 1890.)

This book is an admirable companion to the one which we have just noticed, not that its contents have anything in common; indeed, there is a contrast. Prof. Perry's demonstrations are suggestive of noise, rapid motion, and of physical exertion, while no experiments could well be more silent and full of quiet beauty than those of Mr. Boys. Some parts of his book exhibit a dry humour of a very rare order, notably the instructions for exhibiting conic sections by the shadow of a bedroom candlestick.

We have never had the good fortune to hear Mr. Boys lecture on this subject, but have seen some of his experiments repeated by others, and have ourselves attempted a few of them. We do not think that any apology is necessary for the innovation which the author makes in devoting the concluding portion of the book to a few hints on performing the experiments. Many of them are easily done, and nearly all of them are instructive. A few, like some of Prof. Perry's, are somewhat akin to conjuring or juggling. But at this season of the year the boundary, if there be one, between scientific apparatus and toys lacks definition.

Mr. Boys' subject, like that of Prof. Perry, while it is a fascinating amusement for children, teems with mathematical mysteries of a high order of inscrutability. The forces of surface tension and kindred molecular phenomena are ever present, while the pliant bubble films in responding to them are moulded into curves and surfaces in which any geometrician may revel. The mathematics of top-spinning, on the other hand, are of a boisterous kind; moments, momentum, and moments of momentum are there, wobbling and whirling may be expressed in complex angular velocities round innumerable axes, which chase each other in various planes, and any rigidity that is to be found is due to extremely rapid motion. Mr. Boys' bubbles ask for such passive expressions as conic sections and their roulettes, and when he examines a body in motion, such as a fountain or a falling drop, he first bids it stay, and under an intermittent illumination watches the silvery beads that appear to hang at rest in the darkened lecture room. Two trifling criticisms may be offered. The diagram in Fig. 11, showing the repulsion of a wet and a non-wetted plate and the accompanying explanation are not clear, and the roulettes of the conic sections are drawn on far too small a scale. It would, perhaps, be hardly in keeping with the bedroom candle experiment to suggest that before commencing soap bubble experiments in an ordinary room, it is advisable to lay down a few newspapers on the table and floor. One fault is to be found in both of these charming books, and the publishers are probably more to blame than the authors—each page bears the title of the book instead of a head-line describing the contents below it.

## ELECTRIC LIGHTING PROGRESS IN LONDON.*

BY F. BAILEY, ASSOC. M.INST.C.E.

The last Paper on electric lighting read before the Society was by Mr. R. E. B. Crompton, in 1888, when he placed before you some of the difficulties and obstacles which were retarding the progress of electric lighting. The rapid progress made within the last eighteen months will, however, show that these difficulties have to a great extent been removed by a number of supply companies having obtained Parliamentary powers to lay mains within certain specified areas into which London has been divided. I propose, therefore, to place before you in general terms the work done and in progress by the various companies, as the time at my disposal will not permit me to give minute details of generating stations and systems.

Although the development of electric lighting has been so rapid within the last ten years, it must not be forgotten that the arc light was shown at the Royal Institution in 1809, and remained a scientific curiosity until 1848, when Staite gave a public exhibition of his arc lamp from the portico of the National Gallery in Trafalgar-square. The *Illustrated London News* of that time contains a drawing of the scene with the following remarks:—"The electric light possesses no novelty. Year after year it has been exhibited at every course of philosophical lectures since the time of Sir Humphry Davy, and therefore really its practicability forms the whole subject for consideration." The electrical energy for this light was obtained from a primary battery; and it is probable that the practicability of this method of obtaining light will continue to remain a subject for remote consideration. At this time the seed sown by Faraday's discovery, in 1831, of electro-magnetic induction had fallen on fruitful soil; and the wonderful dynamos of to-day form a suitable monument to his genius.

You will see, therefore, that electric lighting commenced its career in London, and London ought, therefore, to show the greatest progress. The incandescent lamp, in some form or another, is mentioned almost yearly from 1836 onwards, and I propose at once to jump to the period when Swan in England and Edison in America brought out the present form of lamp.

Through the kindness of Mr. J. W. Swan, I have the honour to show you the first lamp he made. It is to be hoped that this lamp will eventually come under the care of one of our great museums, in order that future ages may recognise the genius of Mr. Swan.

I have also to thank Mr. Sydney Morse for the loan of another valuable historical lamp, this being the first lamp constructed by Edison.

Time does not permit me to trace the history of the incandescent lamp, or the extraordinary development of its manufacture. Nothing could have been done practically without the mercury pump, and we ought, therefore, to place the inventor, Dr. Sprengel, in a high position on our records of pioneers.

Turning to the record of general distribution of the electric light in London, you all know that practically nothing was done under the Act of 1882, but private enterprise provided fields for encouraging the efforts of the electrical engineer, and foremost amongst these must be mentioned the Grosvenor Gallery station, which did such good service in making the capabilities of the light known, and in proving the absolute necessity that existed for it; for however defective the supply may have been towards the close of the existence of the station (owing to the plant being overloaded), we owe a debt of gratitude to Lord Crawford for his energetic support to this enterprise, and to those who worked so hard to bring it to perfection. Mr. Ferranti, and those who worked with him at the Grosvenor, laid the foundation-stone of a satisfactory transformer system, and as they had no Parliamentary powers to lay down underground mains, overhead lines were run in all directions. The perfection to which they brought the details of overhead construction is so fully proved by the absence of accidents that it is much to be regretted that the overhead conductors in the United States were allowed to have been put up with no regard to common sense or safety.

It is frequently stated that the Electric Lighting Act of 1882 did much towards stifling inordinate speculation, but in attempting to make people wise by this Act of Parliament, a very serious check was placed upon the development of electrical progress.

The enormous strides which have been made under the more encouraging Electric Lighting Act of 1888 will convince everyone that it was urgently required, and electrical engineers fully realise what they owe to Sir Frederick Bramwell for his share in framing this Act. One of the consequences of this Act was a deluge of applications for Provisional Orders. A court of inquiry was therefore ordered by the Board of Trade, who appointed Major Marindin as their inspector for this purpose.

If you carefully read the eighteen days' evidence given, you will probably be convinced that every system was the best. The inquiry lasted several days, and resulted in the granting of Provisional Orders, confirmed by Parliament in August, 1889, to the companies mentioned in the summary on opposite page, which also includes other information.

I must here gratefully acknowledge the very cordial assistance which the engineers of the various companies have given me.

We will now very briefly go round the stations of the companies, commencing with

### *The Kensington and Knightsbridge Electric Light Company.*

This Company commenced work under the name of the Kensington Court Electric Light Company in the autumn of 1886, and under Mr. Crompton's able guidance made such rapid progress that they commenced to supply current in January, 1887, using underground mains and running their plant in a temporary building. The Board of Trade license under which the work commenced being incorporated in the company's Provisional Order of 1889, which authorises them to supply a portion of the parish of Kensington, St. Mary Abbott, and the detached portion of the parish of St. Margaret, Westminster.

* Paper read before the Society of Arts, December 10, 1890.

* Temporary station. † Now in progress. ‡ Nearly complete, and another station not yet commenced. § As published in the *Engineer*, 24th October, 1890.

The direct current is employed in conjunction with "Howell" secondary batteries, the pressure being 200 volts on the 3-wire system, with 100 volts in the houses.

The batteries are charged at any convenient time when the engines have power to spare, and not only act as a sponge, which can be squeezed when the engine plant requires assistance, but also act as regulators, as well as maintaining the supply during the hours of minimum demand. The satisfactory use of secondary batteries in this manner has attained its present development mainly through the indefatigable labours of Mr. J. C. Howell.

Two generating stations are erected, one at Kensington-court, (*The Electrician*, Vol. XXV., p. 381), and the other at Chapel-place, Knightsbridge, the plant consisting of "Babcock and Wilcox" boilers and exhaust steam feed water heaters, "Willans" compound engines combined direct with Crompton dynamos and "Howell" batteries in both stations. There is also a battery station situated near the centre of the Kensington district at Queen's-terrace-mews, where two large "Howell" batteries are placed. In all cases ample space is provided for the future extension of the plant when required. Arrangements are provided on the Kensington-court station switchboards to enable any dynamo to be used for charging the distant battery station to which a pair of charging mains are laid. Mr. Crompton also designed for this company a system of mains of considerable novelty which was severely criticised at the time but has since proved most satisfactory.

Culverts constructed with concrete or brickwork are laid under the pavements, and bare copper conductors, supported at intervals by glass insulators, are placed in these culverts. The conductors are composed of copper strips, 1 inch by ¼ inch, laid one over the other so as to make up the total section required. In cases where there is no room under the pavement in which to build up the culvert, wrought-iron gas tubing is used, and cables insulated with thick vulcanised rubber are drawn through and connected to the bare conductors. Numerous service boxes are fixed in the pavements to enable houses to be connected without opening the ground. Four and a-half miles of pipes with cables have been laid. (*The Electrician*, Vol. XXIV., p. 343.

On December 1st lamps were connected to an equivalent of 24,850 32-watt lamps, and Mr. W. H. Miller, the company's engineer, to whom I am indebted for these particulars, informs me that the lamp supply, or maximum number of lamps in use at one moment, is between 30 and 40 per cent. of the lamp connection.

### *The House-to-House Electric Light Supply Company.*

This company, as you see on the map on the wall, covers a large area, which consists of two detached districts, practically North Kensington and West Brompton. The generating station is situated off the Richmond road, West Brompton, and contains space for a very large plant. (*The Electrician*, Vol. XXVI., p. 42.)

The Lowrie-Hall alternating current transformer system is adopted, with 2,000 volts on the mains. Four principal mains at present carry the current from the station, the transformers being connected to these mains where required. Cast-iron pipes are laid to form a conduit into which vulcanised india-rubber "Silvertown" cables are drawn; suitable manholes, covers, and junction-boxes being provided.

At present the demand for light is supplied from a plant consisting of :—

Digitized by Google

Three "Babcock and Wilcox" boilers, working at 150lbs per square inch.

Three "Fowler" compound horizontal engines, each of 200 indicated horse-power.

Three "Lowrie-Hall" alternators, each of 100 units 2,000 volts.

Three "Elwell--Parker" exciters, each of 3 units.

The engines work at a speed of 88 revolutions per minute, each engine driving 1 alternator by 7 cotton ropes, the exciter for each alternator being driven by cotton ropes from the alternator pulley.

The Lowrie-Hall pressure regulator and recording instruments are also used. Mr. Hall, the Company's manager, has kindly given me this information, and states that on their lamp connections, equivalent to 12,898 lamps of 8 candle-power, the maximum lamp supply is equivalent to 5,430 lamps of 8 candle-power—say 42 per cent.

*St. James's and Pall Mall Electric Lighting Company.*

This Company was formed for the purpose of supplying the whole of the parish of St. James's, Westminster, and commenced to supply current under their provisional orders from their station in Mason's-yard, Duke-street, on April 4, 1889.

The direct current is employed without batteries.

At present the above station supplies the southern half of the district, the total plant consisting of :—

Five "Davy-Paxman" boilers, working at 150lb. per square inch.

Two large Berryman feed water heaters.

Ten Willans' compound engines, each of 200 indicated horse-power.

Two Willans' compound engines, each of 80 indicated horse-power.

Twelve dynamos, "Latimer Clark, Muirhead and Co.," and "Siemens," driven direct from the engines.

The whole of this plant is neatly arranged, so as to occupy the least space.

The mains consist of a network of conductors on the three-wire system, supplied at about 100 volts at the station by suitable feeders. A cast-iron trough or culvert is laid under the surface of the pavement, and three conductors, each consisting of a number of strips of bare copper, which can be added to at any time, are carried by porcelain bridges, placed at suitable intervals apart. To avoid any risk of the mains touching each other, porcelain distance-pieces are placed over the mains. A cast-iron lid, with water-tight joint, covers the trough. Connection to customers' houses is made by drawing well insulated cable through gas-tubing, which is screwed into the trough. (*The Electrician*, Vol. XXIV. p. 369).

On the 5th December, a total, equivalent to 23,174 lamps of 8 candle-power, were connected. Mr. Dobson, the Company's engineer, kindly informed me that the maximum lamp supply is equal to about 13,222 lamps of 8 candle-power—say 57 per cent.

*The Westminster Electric Supply Corporation.*

The district in which this Corporation is authorised to supply electricity by its Provisional Order comprises that portion of the united parishes of St. Margaret and St. John, Westminster, which lies to the south of the centre line of the Metropolitan District Railway, and the portion of the parish of St. George, Hanover-square, covering Belgravia and Mayfair.

The system adopted is similar to that of the Kensington and Knightsbridge Company, direct current in conjunction with batteries used as regulators, and also for supply during hours of minimum demand.

Three stations are being erected, one at Millbank-street, one at Eccleston-place, and one in Davies-street. (*The Electrician*, Vol. XXV. p. 741).

Current is now being supplied from the Millbank-street station and from a small temporary station in Dacre-street. The other two are being pushed forward as fast as possible, in order to supply from all stations early in the year.

Mains are being laid for a three-wire distribution, Messrs. Crompton being the contractors for the Westminster district, where the system adopted is similar to that put down by Mr. Crompton for the Kensington and Knightsbridge Company.

For other parts of the district Prof. Kennedy, the engineer to the Company, has devised the arrangement shown in the plan on the wall ; bare copper strip rests on stoneware insulators placed from six to eight feet apart, and bedded in the concrete culvert as shown. The copper is stretched by a special tool before being pulled in, and this process gives it sufficient stiffness not to sag perceptibly between the insulators. The total sectional area of the conductors can be increased when required by the addition of more copper strip. Feeders are used in a most systematic manner, and Prof. Kennedy is to be congratulated on the favourable prospects of this Company's work. There is a large demand for light in the district, and the rapid progress of this Company justifies the expectation of a speedy supply from the stations now in progress.

*The London Electric Supply Corporation.*

The Parliamentary powers possessed by this Company cover a large area, comprising the district bordering the south side of the Thames from Westminster-bridge to Greenwich, Mayfair, Belgravia, St. James and Pall Mall, St. Martin's-in-the-Fields, part of Westminster, Chelsea, and two isolated areas, namely, Newington and Clerkenwell.

The Ferranti system is employed throughout, alternating current being generated at an extra high pressure and transmitted to converting stations, from which it is distributed at high pressure to the service converters.

The Corporation has erected a large station at Deptford, which has been admirably designed for the purpose, having road-frontage, wharfage, and coaling dock. The plant consists of 24 "Babcock and Wilcox" boilers, 4 compound vertical engines by Hick and Hargreaves, two of which are 1,500 indicated horse-power each, and two of 750 indicated horse-power each. There is almost unlimited room for future extension.

Each of these engines drives a Ferranti dynamo by cotton ropes, the exciters being driven direct from independent engines.

In order to convey the high pressure from Deptford to London, Mr. Ferranti devised a special form of main for this purpose, which has been frequently described.

About 28 miles of these mains have been laid, the distributing mains from the converting stations being of various kinds. This Company's Grosvenor Gallery station having lately been closed, a hurried change has had to be made in order to enable the Corporation to supply from Deptford.

*Chelsea Electricity Supply Company.*

This Company's Provisional Order covers the whole parish of Chelsea, a portion of which the Company is now supplying.

Direct current is employed with accumulators, but, unlike the other companies in London, in this case the accumulators are charged with a high pressure current, and discharge direct at low pressure into the mains. I am not in possession of any information of this Company's progress. From published descriptions you will doubtless be aware that the generating station is situated at Draycott-place, with battery stations at Clabon-mews, Egerton-mews and Pavilion-road.

*The Electricity Supply Corporation.*

This Company obtained a Provisional Order in 1889 for supplying the whole of the parish of St. Martin's-in-the-Fields. Direct current, without batteries. The station is placed just off the Strand, and was laid down, some years ago, by Messrs. Gatti to supply the Adelaide Gallery and the Adelphi Theatre ; it is now being extended. At present the plant consists of :—

Four "Babcock and Wilcox" boilers.

Five Willans' engines, amounting to 600 indicated horse-power.

Five "Edison-Hopkinson" dynamos, each being driven direct from one engine. Callender mains are laid down in Callender-Webber casing.

*St. Pancras Vestry.*

The Vestry have decided to carry out the electric lighting of the parish themselves, and have secured the able services of Professor Robinson as their engineer. The direct current system will be adopted, and a station is now being erected in Stanhope-street, Euston-road, for the supply of the south-west portion of the parish.

*Notting-hill Electric Lighting Company.*

The Provisional Order granted to this Company includes the district of Notting-hill, which comes within part of the parish of Kensington, St. Mary Abbott.

The system is similar to that adopted by the Kensington and Knightsbridge Company.

The first generating station, situated off High-street, Kensington, is now approaching completion, the plant consisting of Babcock and Wilcox boilers, Willans engines, Crompton dynamos, and Howell batteries ; Crompton's mains are also laid as shown in the map on the wall.

*The Metropolitan Electric Supply Company.*

The Parliamentary powers of this Company include the large and important districts of Paddington and Marylebone parishes, with part of St. Martin's-in-the-Fields, the Holborn and Strand district, and St. Giles' Board of Works.

Various systems are employed by this Company, both the alternating and direct current systems being adopted.

The Company is at present supplying from four stations, and it may perhaps be better to describe them separately.

The Whitehall station, situated in Whitehall-avenue, is a direct current station which possesses no novelty, and supplies the surrounding locality, the plant consisting of Hick-Hargreaves boilers, Willans engines, and Siemens dynamos. Callender mains are laid down the Northumberland-avenue subway and elsewhere.

Digitized by Google

The Sardinia-street station (*The Electrician*, Vol. XXV., p. 703), contains a complete plant on the Westinghouse alternating current system, consisting of twelve Babcock and Wilcox boilers, working at 150lb. per square inch; twelve Westinghouse alternators, each being belt-driven by a Westinghouse compound engine. There are also three exciters, each being belt-driven by its own engine.

The Manchester-square station (*The Electrician*, Vol. XXVI,, p. 69), contains nine Babcock and Wilcox boilers, ten Parker alternators, each driven direct by a 200 horse-power Willans engine, as shown in the sketch of the engine-house placed on the wall. There are also four exciters, each being driven direct by a Willans engine. The steam piping is arranged on a method devised by Mr. J. H. Rosenthal, the London manager of the Babcock and Wilcox Boiler Company, and possesses many advantages.

The Rathbone-place station (*The Electrician*, Vol. XXVI., p. 109), contains plant of a similar kind, there being five boilers, six alternators and engines, two exciters and engines.

The system of distribution from the three latter alternating current stations is of a simple description—cast-iron pipes laid underground form conduits, into which "Silvertown" vulcanised rubber cables have been drawn when required. Split T-pieces are inserted in the pipes for connection to customers' premises. These mains are looped from house to house, returning to the station, so as to form complete rings. Each customer has, therefore, a duplicate supply, thus enabling new customers to be connected to the system without interrupting the supply on the circuit.

All these three stations are connected together by trunk mains, which enable one station to assist another, or take the whole load of the district during the hours of least demand. The current leaves each of these stations at a pressure of 1,000 volts, this moderate pressure being adopted as the number of supply stations reduces the distance to which each cable has to be laid to meet the demand. The whole supply is distributed by a number of small cables, which can be easily replaced when required.

The demand for light has been very encouraging; and, as you will see from the Table, the progress of the lamp connection to these stations has been very rapid. I regret, however, to say that, although this Company at present supplies light to twelve public-houses, only four churches are, so far, connected with the system.

Having now completed our tour of the stations of the various companies, we have seen how the streets of London have lately been disturbed in order to lay all these mains; no doubt a certain amount of inconvenience has unavoidably been caused to traffic, but it has revealed the wonderful system of organisation by which London is governed; and the vestry surveyors, whose labours have been much increased, have not only afforded every facility for carrying out the work, but have rapidly re-instated the pavements at, of course, the cost of the respective electric light companies. The public, therefore, though for a short time inconvenienced, have in reality secured new pavements for old.

Summarising the plants adopted by the various supply companies, it is interesting to notice how the peculiar conditions of electrical supply in the very limited space usually available have been provided for by manufacturers. As an instance of this, it may be noted that "Willans" engines, amounting to about 9,000 horse-power, are used by the public supply companies in London, and similar engines, aggregating more than 2,000 indicated horse-power, for private plants in the metropolis. The Babcox and Wilcox boiler having also been so universally adopted, it may be of interest to state that 78 boilers of this type, supplying 14,230 indicated horse-power, are now at work in London.

*Private Plants.*

One result of the Act of 1882 has undoubtedly been to cause a large number of private installations to be erected, but so many of our leading electric light contractors have laid down thoroughly efficient plants that there is perhaps no cause for regret. Most of the large terminal London railway stations work their own electric light machinery, the largest installation being at Paddington, (*The Electrician*, Vol. XVII., p. 51), where the Great Western Railway Company have machinery of 1,500 horse-power for this purpose. For residences, gas-engines provide the motive-power for driving dynamos supplying about 18,000 lamps of 32 watts each, the remainder being steam-driven.

It may be of interest to note that the Crossley "Otto" gas-engine, which was awarded a gold medal at this Society's recent motor competition, is being employed for this purpose, amongst others, by Messrs. Laing, Wharton and Down. This total may appear large, but it must be remembered that many of the large hotels having their own steam plant for working lifts, warming and cooking, have added electric lighting machinery; the total also includes the lamps at D'Oyly Carte's new theatre, where Messrs. Verity have erected a plant so complete that it may almost be considered as a small central station.

*Number of Incandescent Lamps now in Use in London.*

With the kind assistance of the electric light contractors, particularly Messrs. Verity, Laing, Wharton and Down, Phipps and Dawson, Drake and Gorham, Sharp and Kent, and many others, and the public supply companies, I have been able to collect data that the total equivalent number of 32 watt lamps now in use in London is approximately as follows :—

| | |
|---|---|
| Public Supply Companies ................................ | 179,060 |
| Private Plants.................................................. | 85,000 |
| Total............................ | 264,060 |

At the present rate of increase a very moderate estimate gives an addition of at least 4,000 lamps per week, and there is little doubt that this number will be greatly exceeded at no distant date. All these incandescent lamps have been calculated on a basis of 32 watts or 8 candle-power lamps, as experience has shown that this is a size much used in London, and, by taking the smallest lamp, we avoid dealing with half lamps.

Before leaving these particulars, it will probably be of service to the designers of future stations if we tabulate the data collected.

*Table Showing Percentage of Maximum Lamp Supply at any Moment to Total Lamp Connection.*

| Station. | Percentage |
|---|---|
| House-to-House ................................................ | 42 |
| Kensington and Knightsbridge ........................ | 30 to 40 |
| St. James' and Pall-mall ................................. | 57 |
| Sardinia-street.................................................. | 45 |
| Rathbone-place ................................................ | 64 |
| Manchester-square ........................................... | 45 |

It may perhaps be of interest if I draw your attention to the following Table, based upon data which has come under my observation, showing the candle-power of lamps mostly used :—

*Lamps (50 volts).*

| 8 c.p. | 16 c.p. | 32 c.p. | 50 c.p. | 100 c.p. | 200 c.p. | 500 c.p. |
|---|---|---|---|---|---|---|
| 597 | 1,666 | 62 | 13 | 8 | 8 | 3 |

*Lamps (100 volts).*

| 8 c.p. | 16 c.p. | 32 c.p. | 50 c.p. | 100 c.p. | 200 c.p. | 500 c.p. |
|---|---|---|---|---|---|---|
| 5,437 | 5,131 | 176 | 26 | 57 | 40 | 3 |

During 1886 and part of 1887 I was able to collect the following data of the behaviour of incandescent lamps, each of 25 candle-power, with an efficiency of 3½ watts per candle, and I trust that more information of this kind will be collected :—

*Incandescent Lamps.—Life, and Nature of Fracture.*

All Lamps 25 c.p. Brass Collar, Edison-Swan.

| Lamps. | | | Nature of Failure. | | | | | | | | | | | |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | | | Glass Globe. | | | | | | Filament Fractured. | | | | | |
| Volts. | No. of lamps renewed. | Average life hours. | Broken. | Per cent. | Blackened. | Per cent. | Plaster. | Per cent. | Loop. | Per cent. | Stem. | Per cent. | Joint. | Per cent. |
| 151 | 536 | 861 | 114 | 21·2 | 21 | 3·91 | 56 | 10·44 | 208 | 38·80 | 114 | 21·26 | 23 | 4·29 |
| 142 | 189 | 789 | 19 | 10·0 | 4 | 2·11 | 41 | 21·69 | 67 | 35·45 | 47 | 24·96 | 11 | 5·82 |
| 120 | 2,549 | 923 | 273 | 10·7 | 92 | 3·60 | 334 | 13·1 | 1,114 | 43·70 | 693 | 27·10 | 43 | 1·68 |
| 99 | 588 | 1,423 | 122 | 20·0 | 61 | 10·37 | 92 | 15·64 | 212 | 36·00 | 95 | 16·10 | 6 | 1·02 |
| | 3,862 | | 528 | | 178 | | 523 | | 1,601 | | 949 | | 83 | |
| | | | | 13·67 | | 4·61 | | 13·54 | | 41·46 | | 24·57 | | 2·15 |

With reference to arc lighting considerable progress is being made; and although the number now in use in London does not much exceed 1,000 lamps, there is no doubt that rapid progress will be made.

Prof. Silvanus Thompson, in March, 1889, showed you all the best known arc lamps; and for further information of their development, I must refer you to his most complete Paper on this subject, published in the Society's *Journal*, March 8, 1889. (*The Electrician*, Vol. XXII., p. 534).

It is a matter for regret that there is no progress to be noticed in connection with the efficiency of the incandescent lamp, which remains much the same as it was five years ago. It will be apparent from the table showing the candle-power of lamps mostly used that a really efficient 100 volt 8 candle-power lamp is much needed; the present lamps of this kind have such a short life that customers, contractors, and electric supply companies would all hail its advent as a boon.

We must also remember that the future progress of electric lighting depends in no small measure on the lampmakers, and as the manufacture of the incandescent lamp will soon be open to all (owing to the expiration of the present patents) the absolute necessity of a standardising laboratory must compel its adoption where not only instruments but lamps can be tested, so that people may know when they ask for an 8 candle-power 100 volt lamp, with or without a guaranteed life of, say, 1,000 hours at an efficiency of 3½ watts per candle, that they get what they have asked for.

That this question of lamp efficiency is of importance to customers and supply companies alike few will doubt, and the following table will probably explain itself:—

| Watts per candle. | Candles per 1,000 watts. | Lamps per 1,000 watts. | | | |
|---|---|---|---|---|---|
| | | 8 c.p. | 16 c.p. | 20 c.p. | 32 c.p. |
| 2·00 | 500·0 | 62·5 | 31·2 | 25·0 | 15·6 |
| 2·25 | 444·5 | 55·5 | 27·7 | 22·2 | 13·9 |
| 2·50 | 400·0 | 50·0 | 25·0 | 20·0 | 12·5 |
| 2·75 | 363·6 | 45·4 | 22·7 | 18·2 | 11·4 |
| 3·00 | 333·3 | 41·7 | 20·8 | 16·7 | 10·4 |
| 3·25 | 307·6 | 38·4 | 19·2 | 15·4 | 9·6 |
| 3·50 | 285·7 | 35·7 | 17·8 | 14·3 | 8·9 |
| 3·75 | 266·6 | 33·3 | 16·7 | 13·3 | 8·3 |
| 4·00 | 250·0 | 31·2 | 15·6 | 12·5 | 7·8 |

We see then how an improved lamp efficiency will benefit the supply companies, by enabling them to increase their lamp connection.

The following table will appeal most strongly to all users of the incandescent lamp; but it must be assumed that an increased efficiency is not obtained at the expense of a reduced life of the lamps.

The most satisfactory feature, however, of the present Edison-Swan lamps is the uniformity of their voltage; and the scientific department of the Edison and Swan Company's works is to be congratulated on the assistance they have given to the industry by practically enabling voltmeters to be set by photometrical tests of the lamps.

*Cost per annum per 8 candle-power lamp at 8d. per unit, lamps burning an average of:—*

| Per day. | ½ hour per day. | 1 hour per day. | 2 hours per day. | 3 hours per day. | 4 hours per day. |
|---|---|---|---|---|---|
| Hours per Annum. | 182·5 | 365 | 730 | 1,095 | 1,460 |
| Cost per annum with lamp efficiency of:— | | | | | |
| | £ s. d. | £ s. d. | £ s. d. | £ s. d. | £ s. d. |
| 2 watts per candle | 0 1 11 | 0 3 11 | 0 7 10 | 0 11 9 | 0 15 8 |
| 2·25 ,, | 0 2 2 | 0 4 5 | 0 8 9 | 0 13 2 | 0 17 6 |
| 2·50 ,, | 0 2 5 | 0 4 10 | 0 9 9 | 0 14 7 | 0 19 6 |
| 2·75 ,, | 0 2 8 | 0 5 4 | 0 10 9 | 0 16 1 | 1 1 5 |
| 3·00 ,, | 0 2 11 | 0 5 10 | 0 11 8 | 0 17 6 | 1 3 4 |
| 3·25 ,, | 0 3 2 | 0 6 4 | 0 12 8 | 0 19 0 | 1 5 4 |
| 3·50 ,, | 0 3 5 | 0 6 10 | 0 13 8 | 1 0 5 | 1 7 3 |
| 3·75 ,, | 0 3 8 | 0 7 4 | 0 14 7 | 1 1 11 | 1 9 2 |
| 4·00 ,, | 0 3 11 | 0 7 10 | 0 15 8 | 1 3 6 | 1 11 4 |

It may be thought that an estimated use of a lamp for only about 200 or 300 hours per annum is very low, but it should be remembered that the electric light need only be used when it is required, as the ease of switching it on and off makes us forget all our past troubles in hunting for gas taps, matches, and broken gas-globes. With ordinary care, the average cost of burning an 8 candle-power lamp for ordinary domestic use need not exceed ten shillings per annum.

Of course much depends on the wiring contractor, who not only has to be an accomplished art critic in designing or selecting the brackets, pendants, &c., but he also has to suggest the most advantageous positions for the lamps and switches. A switch placed near the door of every room, and not less than two lamps in any room will probably save annoyance.

The greatest progress has been made in the wiring of houses; not only is more work done, but it is better done and on more mechanical principles, for whereas some years ago a single main would have been run from top to bottom of a house with numerous T-joints, independent circuits will now be wired, and all brought to a neat form of distributing board.

The effect of the extra care which is now taken with this work is proved by the following table of insulation tests, taken with 100 volts at 200 houses:—

*Insulation tests of internal wiring (taken with 100 volts—Evershed Ohmmeter.)*

| Number of Points. | | Test Megohms. |
|---|---|---|
| 5 to 10 | Average of 15 houses | 4·0 |
| 10 „ 15 | „ 23 „ | 3·5 |
| 15 „ 20 | „ 18 „ | 2·8 |
| 20 „ 25 | „ 13 „ | 2·7 |
| 25 „ 35 | „ 33 „ | 1·8 |
| 35 „ 40 | „ 12 „ | 1·5 |
| 40 „ 50 | „ 16 „ | 1·2 |
| 50 „ 60 | „ 12 „ | 1·1 |
| 60 „ 70 | „ 9 „ | 1·0 |
| 70 „ 120 | „ 14 „ | ·4 |
| 120 „ 220 | „ 9 „ | ·25 |

I hoped to have been able to place before you some record of the improvement in the health of London owing to the progress of electric lighting, but so much has already been said and published about it that further facts appear needless. It is simply melancholy to see so many of our churches and halls not only burning their gas-jets for lighting, but also for "warming" the building. If culpable negligence amounts to manslaughter, the people responsible for this atrocity ought to receive their deserts.

Having now placed before you some account of the progress of electric lighting in London, I must ask you to compare our metropolis with other cities, and leave you to judge whether we are so far behind them as some would have us believe. Is it not more probable that other countries will be glad to avail themselves of the experience which London must gain in the working of so many distinct systems?

## DISCUSSION.

The CHAIRMAN said Mr. Bailey had been good enough to attribute to him a share in the Act of 1888, which he must disclaim. He took an active part in preparing a Bill which was not passed, and the one which did become law, for which they had mainly to thank Lord Thurlow and his colleagues, was one which he regretted was accepted, because it left in full force what he considered the vicious principle of Government trading, though it extended the previous impossible term of 21 years to 42, a term which he had hoped would also have been treated as impossible. Under the Act of 1882, public electric lighting in England was impossible, and progress was greatly retarded in consequence. Some astonishment had been expressed at the large number of private installations as compared with public one—practically half the number of lamps—but that was entirely due to that Act. People wanted the electric light, and as the Legislature prevented it from being supplied in the ordinary way in which such illuminants as gas was supplied, those who had the requisite means and space at command did it themselves.

Mr. R. E. CROMPTON said electric engineers might feel proud that, although they had been so heavily handicapped in the race, they had begun at last to bring London to the front, and it would not be long before they were as far ahead of any other town in the world in electric lighting as they were in most other respects. The Act of 1882 completely stopped electric lighting for several years, though, as engineer to the Edison and Swan Company, he then designed several central stations which, even in the light of present knowledge, he could say could have been carried out practically as well then as they could now. The one at Victoria Station, and another in the Strand district, were, in many respects, as well designed as those he had since been connected with. The chairman of the company at that time, however, thought—probably rightly—that it was not fair to put the shareholders' money at the mercy of the provisions of that Act, under which the undertaking could be purchased at breaking-up price at the end of such a short period, and the scheme was therefore never carried farther than the lighting of Victoria Station, though it could have been worked, within a small percentage, as economically and as well as many which had been started recently. In that station, the dynamos were on the upper floor

Digitized by Google

Five years ago, a gentleman called at his office and said he was connected with an estate company which had a subway, so that underground mains could be laid without coming under the Act, and the result was the formation of the Kensington-court Company, his informant being Mr. Granville Ryder, the present Chairman of the Company. At that time not a single underground main had been tried, and, but for this opportunity of testing the system, it was very improbable that either the Kensington-court, the Whitehall, or the Metropolitan Company would have occupied the positions they now did. The public should know that though they might have been inconvenienced by the breaking up of the streets, it was a very different thing from similar annoyances on the part of gas and water companies, because in most cases the work was done once for all. Conduits or pipes had been laid, into which the conductors could be drawn, and from which they could be withdrawn and repaired, so that connections could be made without further breaking up of the road. He did not know the exact mileage, but he should think nearly 150 miles had already been laid, which was no small feat to accomplish, since the provisional orders were obtained two years ago. In the system of underground conductors with which Mr. Bailey had connected his name —though he was by no means the sole inventor, many other engineers having contributed to its development—the idea was not only to give access to every house for the electric light, but to afford sufficient means of access for many other systems of conductors in future—telephone wires, fire alarms, and other means of communication, which would be greatly appreciated in future.

Professor KENNEDY, F.R.S., said this paper would be much quoted after a few years, for Mr. Bailey had given a most vivid picture of the state of electric lighting in London, just at the time when it was most interesting. As to the maximum number of lights at one time in use as compared to the total number on the station, he had been apparently very fortunate in one of his own districts. He had found in Westminster the usual average was about 40 to 42 per cent., but one foggy day in last week it went up to 60 or 61, judging from the amount of current going out. As to the state of electric lighting in London compared with other places, there was no other city in the world that had 250,000 lights, or anything like it. He believed it was about double the amount in use in New York, and before long people would be coming here for information, instead of scoffing at us for doing nothing. With regard to safety in working a station, he thought that there should always be power in reserve equal to one of the largest units; if 200 horse-power engines were the largest used, for instance, there should be 200 horse-power in reserve, but the use of one 500 horse-power engine necessitated at least 500 horse-power in reserve, and so on. He should be glad to think that putting a boiler on a lower level than the engine would ensure having dry steam, but rather doubted whether that was proved experimentally. If the particular boilers mentioned gave dry steam, he did not think it could be owing to their position in reference to the engine.

Professor FORBES, F.R.S., said that Mr. Bailey had collected an enormous number of the very facts engineers wanted to arrive at, and he hoped other gentlemen connected with central stations would follow his example and give the result of their experience. Mr. Bailey seemed rather hurt because various people had criticised the progress of electric lighting in this country, and contrasted it unfavourably with what was done elsewhere, and perhaps few had done more in that way than he (Mr. Forbes) had. He had taken the pains to learn what was being done in foreign countries by personal inspection, and had frequently, on his return from such inquiries, done his best to impress on those concerned at home the superiority of the work which was being done abroad. The last time he had occasion to do so was about three years ago, when hardly any of the work now described had been commenced; but he now thoroughly endorsed what had been said by Professor Kennedy, that there was not an example in the whole world of such enormous progress in so short a time. They were delayed for a long time by the former Act, but during all that time they were studying what was done elsewhere, so that when they began they were on sure ground, and went ahead with more confidence than people elsewhere had done. Not only was the scale of work greater in London than anywhere else, but the character of the work in the central stations would bear comparison with any. Anyone who had visited the Sardinia-street station would feel that it was as complete and satisfactory as it could possibly be.

Mr. W. M. MORDEY said that he believed this paper would be of the greatest value. He suggested that it should be followed, at fairly frequent intervals, with other accounts of the work that was actually being done. He remarked that Mr. Bailey's particular arrangement of primary mains, which was very simple and ingenious, had not been alluded to in the paper. It would be very useful if they could have not only the relative life of 50 and 100 volt lamps but their relative efficiency. It would be well to know how much the lowering of the candle-power of the former counter-balanced the advantage of the longer life, the blackening of the globe in a low voltage lamp being always more serious than in the case of a high one. A strong confirmation of what had fallen from the Chairman and Mr. Crompton as to the effect of the Act of 1882 was to be found in experience abroad. It was often stated that our knowledge of how to distribute electricity had greatly advanced since 1882. This was true, but it was also true that, so far as supplying lights in a densely inhabited district was concerned, no great advance had been made or was to be expected. As an illustration of this, he referred to Milan, where a large scheme had been carried out on the lines that were available in 1882. Just about 1883 a station was put down there which had never had the current off the mains for six years, and it was now supplying 25,000 16 candle-power lamps on the direct low-tension system. The history of that station showed that, in a dense area, the old-fashioned system was very good in its way, even without the advantage of the three-wire arrangement. Distant places—suburbs, and so on—could not be supplied, but they were now supplying the more distant parts on the high-tension system, somewhat similar to that mainly used by Mr. Bailey's company. The history of the Metropolitan Company illustrated the advance in knowledge of how to distribute light over a large area economically, especially in the early stages of the work. That company started with a low-tension system and with batteries; but all the stations added since were on the high-tension system, without batteries. They knew now how to supply both in dense areas and over long distances. Mr. Crompton had, in London, perhaps done more than any one in the former direction, and the Metropolitan Company more than any one—except, perhaps, Mr. Ferranti—in the latter. A great deal had been said by Mr. Preece and others in that room on the advantage of lighting streets by arc lamps. It appeared that there were only about 1,000 in use in London altogether. He thought the general public would never fully appreciate the advantages of electric lighting until the whole of the main streets were illuminated in that way. Nothing had been said about the electric lighting of the city, no doubt for the reason that there was at present no lighting in the city. This reproach would shortly be removed, his company and others having undertaken a general lighting scheme, which, he was glad to say, included street lighting by arc lamps.

Mr. R. W. WALLACE hoped that inventors would turn their attention in the direction of endeavouring to improve incandescent lamps.

Mr. BAILEY, in reply, said that so far as he could ascertain there were now 81½ miles of conduits of all kinds, in some cases pipes, in others concrete or brickwork; and into these conduits were led about 111¼ miles of cable, which were actually carrying current at the present moment; and that had practically been accomplished in eighteen months, in order to supply the public with electric lighting, but they had not yet got to street lighting. That brought him to the question of arc lamps. Everyone would like to see arc lighting, but they could never expect to see it in London in such perfection as in Milan and other places where the streets were practically built for it. One could not imagine the Strand looking particularly handsome, even with the aid of arc lamps; it was quite different in Berlin, where they could be placed in the centre of the roadway on very high masts; but such as the streets of London were, they would be immensely improved by arc lighting, and he believed this would come shortly; and in place of the very meagre account of this system which he had been able to give, he hoped before long to hear someone else give a much more ample description of what was being done in this way. Everything was now ready for it, and he could not quite understand what kept it back. Professor Kennedy had referred to the maximum percentage of supply to the total lamp connection, as to which you might take either the average or the heaviest day, the figures given in the paper being the heaviest lighting day in November; and he found that in all the districts from which he had collected information that the heaviest duty came on between four and five in the afternoon. (He exhibited a number of diagrams showing the varying amounts of current demanded during the day, plotted on a curve, taken at different stations and on different days, the highest point varying according as the district consisted mainly of offices, shops, or theatres and restaurants.) There were over 25 miles of these overhead lines, and he could not remember a single accident attributable to them. The prejudice which existed against them was due to the wretched work done in New York, where they neither suspended the wires nor properly insulated them, but left them to rot, and then people said how dangerous they were. Mr. Mordey had kindly alluded to the arrangement of mains which he was endeavouring to carry out, and which he (Mr. Bailey) did not allude to in the paper because he did not want to advertise himself. There was no particular novelty about it; they were merely acting on mechanical principles, and endeavouring to give people a double supply, one from each end of the cable, so that when a new customer wanted to come on, there was no need to go round to all the subscribers and tell them they must be shut off. With reference to the incandescent lamps, he hoped others would keep a record of the behaviour of all the lamps under their charge, which could easily be done. He had an india-rubber stamp, with a movable date, which was stamped on the cement when the lamp was sent out; when it failed, and was brought in to be replaced, the storekeeper could tabulate the date and the fracture in the filament, and these records would be very valuable. In a few years' time it would be open to anyone to make lamps; and people then would buy from those who produced the cheapest and most durable. Mr. Mordey had referred to the Whitehall Company and the alteration they had introduced in the other districts as the system developed. That was due to the size of the districts which that company had to light; it was not only a question of providing light, but of doing it quickly, for nowadays, as soon as anyone had his place wired, he wanted the current the next day; and if he did not get it, he worried the life out of the unfortunate engineer to the supply company. The other day a certain firm took proceedings against an electric light company for not continuing the supply, and stated on oath that whereas with the electric light they could go for six years without decorating their premises, when using gas they had to paint and whitewash every two years, and they claimed damages in consequence. He hoped the vestries would soon see the advisability of lighting the streets by arc lamps.

The CHAIRMAN, in proposing a vote of thanks to Mr. Bailey, said he prophesied two years ago that in ten years' time 90 per cent. of all the houses at the West-end of London, of £400 a year rental and upwards, would be lit by electricity. He now began to think that he had not been sufficiently sanguine, and that he might have mentioned a rental of £300 instead of £400. So long as gas was supplied at 2s. 9d. or 2s. 6d. per 1,000 feet, the electric light, until improved in some way—and the only improvement that seemed possible was economy in the lamp—must be a light of luxury; but persons who would pay £300 or £400 a year rent were willing to pay £20, £30, or even £40 more for electric lighting, as compared, not with gas, because many would not use it, but with the other illuminants they employed. After a year's experience of the use of a number of lamps equal to about 114 8-candle lamps, he found the extra cost was between

Digitized by Google

£20 and £25, as compared with the gas, candles, and lamps he used before, and in that he made no allowance for decreased expenditure in cleaning, painting, and matters of that kind, which was undoubtedly considerable. He had also a curious experience, during the summer quarter, of the truth of what Mr. Bailey said about the ease with which the electric light was extinguished and re-lighted. His summer quarter's bill for electric lighting was only a few shillings in excess of the gas bill for the previous year's summer quarter, and he bought no candles or lamp oil, having the electric light all over the house. The reason was simply this, that in a dark London basement, even in the summer time, the gas was kept constantly burning, but the electric light was turned out when not wanted, and though no doubt it was considerably dearer than gas, so much less of it was used, even by the servants, that it only cost a few shillings more.

## GAS AND ELECTRIC LIGHTING AND VENTILATION.*

Whatever may be the commercial prospects of central station electric lighting companies in this country, it is undeniable that this means of lighting for places of amusement and large public establishments is a present reality with which those who are interested in the gas industry must in future make their account. Such is the fashion of the time, that only impecuniosity prevents proprietors and lessees of theatres, assembly-rooms, &c., from taking to electric lighting, either as supplied from a central station or generated on the premises, keeping gas only as a reserve in case of accidents. Those proprietors of large establishments who can afford the outlay find it to their advantage to lay down electric lighting plant upon the premises—generating the power by means of gas-engines; because in this way they know what they have to depend upon, and the lighting comes cheaper in the long run. So much lighting is, as a rule, required for the offices, outbuildings, and corridors of places of amusement, that even when electric lighting is adopted for the auditorium and main approach, the gas bill still amounts to a respectable figure; and, of course, where gas-engines are used to generate the necessary power, the suppliers of the gas have no reason to begrudge the electric lamps their place in the best parts of the house. Moreover, it is hardly necessary to say that the better places of public resort are lighted, by whatever means, the better it is for the purveyors of all kinds of illuminating agents, since the heightening of the standard of artificial lighting in any way reacts upon the general estimation of what is desirable in this regard.

The particular object of this article, however, is not to minimise in the supposed interest of the gas industry the actual progress of electric lighting for public buildings—for this would be a vain endeavour, since nothing is ever gained by wilfully misreading the signs of the times—but to discuss the subject with reference to a point of definite public interest. It is scarcely necessary to remark, by way of preface, that the adoption of electric lighting for places of assemblies was originally advocated for two principal reasons—safety from fire and benefit to health. It was assumed that no electrically lighted theatre, for example, could ever burn down during a performance, through anything going wrong with the means of lighting; while it was also supposed, with equal confidence, that the substitution of incandescent electric lamps, radiating *in vacuo* without combustion, for the multitudinous flames of gas-burners, would be a vast improvement in the way of sanitation. Not a great lapse of time has been required, however, to demonstrate the truth that an electric current will set fire to a building, when improperly managed, as well as gas; and it is now universally agreed that the undiscriminating application of electric lighting to places of popular resort is to be deprecated out of consideration for the public safety. This means of lighting can be made practically safe, of course, and so can gas. But in both cases safety must be procured by precaution. Human error is capable of making mischief with either; and this reflection disposes of the claim for absolute and inherent safety once advanced on behalf of electric lighting. It has been seen that a careless workman can burn down an electric light station; and it remains to be proved that carelessness of the same order could not result in the destruction of a theatre.

With regard to the second consideration—that of public health—it may be observed that this is a matter upon which a verdict has been snapped by the electricians without sufficient evidence. They have asserted, and everybody has allowed the assumption, that the adoption of electric lighting in place of gas for theatres, music and lecture halls, &c., has invariably resulted in an improvement of the atmosphere and the prevention of overheating. Now, this is the point which we desire to see settled by reliable investigation. So far as we are aware, nothing of the kind has been attempted. It is true that the examination of the atmosphere of crowded places of assembly, with the express object of testing the efficacy of their ventilating arrangements, is generally neglected. We hear from time to time accounts, more or less after the nature of advertisements, of the methods adopted for the ventilation of public buildings; but it is very rarely indeed that anything is stated afterwards of the way in which these arrangements actually work. Which, for instance, is the best ventilated theatre in London? Can any hall in the Metropolitan area lay claim to a remarkably cool and wholesome atmosphere when packed to its utmost limits, without resort to the heroic procedure of sliding off the roof bodily? It is obvious that until it is exactly known how the ventilation of public rooms works with different means of lighting, it is vain to claim that one is preferable to the other. Incandescent electric lamps are presumed to be less destructive of the purity and coolness of the atmosphere of an enclosed place than gas-flames, because they do not require oxygen, and radiate less heat. Hence comes all the question-begging talk about the "barbarity" of depending upon combustion for light, which electricians use when they desire to emphasise the sanitary advantages of incandescent electric lamps. All this is very plausible, and many are carried away by it. Supposing that we have an enclosed place containing a quantity of oxygen in its atmosphere, a light that requires none will, of course, leave more for other uses than one which consumes this necessary supporter of fire and life. But in point of fact, the problem is by no means so simple as this. Instead of a closed room and a constant quantity of oxygen, any desired supply of the latter may be had from outside. Besides, it is not only a question of the inlet of a current of fresh air for the lights; but this must be done in any case for the human occupants of the room. So that it is only a matter of degree whether oxygen has to be supplied for both purposes or for only one. It is therefore possible to say that the method by which a public hall is lighted cannot make much difference to the fundamental obligation to ventilate it with due regard to the health and comfort of the people who use it. Now, a system has become general for combining the gas lighting and ventilation of public halls by the aid of sun-lights. Where this class of gas-burners is in use an enormous up-current of air is created in the chimney by the burning gas, which at the same time is so high overhead that its radiant heat is practically imperceptible; and this artificial draught sweeps out all the foul air of the upper part of the room, together with the products of combustion. The efficiency of this means of ventilation is only limited by the quantity of gas burnt, the dimensions of the chimney, and the completeness of the arrangements for the supply of fresh air to take the place of what is removed.

It is therefore a mistake to think that the ventilation of any hall lighted in the manner just described will be improved by substituting electric lamps for the gas-burners. Quite the contrary effect is, in reality, to be expected; and there are now facilities enough, through the introduction of electric lighting into places formerly lighted by sun-burners, for an experimental investigation into this important question. We have every reason to believe that the result of such an inquiry would be to show that in many cases the substitution of electric lighting for gas has absolutely upset the ventilation arrangements, without conferring any corresponding advantage of a sanitary order. Incandescent electric lamps do, as a matter of fact, radiate an appreciable amount of heat; but as they are usually distributed, none of this can be utilised for assisting in the work of ventilation. We should not like to say that the quantity of gas needed to create a sufficient chimney draught for changing the air of any hall would be enough to light it, because every separate case must be dealt with according to its special requirements. What we do contend for is that the responsible managers of places of public resort should have their eyes open to the consequences of changing their system of lighting without attending to the ventilation. When the hall is first occupied of any evening, it is possible that there may be a cooler atmosphere with electric lighting than with gas. This difference will soon vanish, however, as the evening wears on, and the ventilation that the gas would ensure is found to be absent. Moreover, in cold weather it is necessary to warm the hall by stove heat; and the want of ventilation then very speedily tells, notwithstanding the imaginary superiority of the electric light in consuming no oxygen. Given a frosty night, a warmed hall, a crowded meeting, and electric lighting, and the condition of the atmosphere of that place, after an hour's occupation, will not be any credit to the method of lighting. We do not speak, of course, of cases where mechanical ventilation is employed; but even then it would probably be found that different systems of lighting make little alteration in the work of changing the air.

There is no need for talking vaguely on this subject; and, in order to bring the question to an issue, we will take a familiar example—the hall of the Society of Arts. This hall is supposed to be ventilated in the so-called "natural," as distinguished from the "mechanical" method, by a sun-light exit shaft, and fresh air admission behind the dado. The sun-light is now replaced by

*From the *Journal of Gas Lighting*.

Digitized by Google

pendants of electric lamps. It would be impossible to exaggerate the stuffiness of this room after half-an-hour's use with closed doors if even only half filled. The question is whether it is better or worse with electric lighting than when gas was solely used. We believe it is much worse; but this is a point the Society ought, in justice to itself, to set right by competent inquiry. Until this is done, and the reputation of the electric lighting is cleared, we shall continue to hold, on *primâ facie* evidence, that the Society's hall is now one of the worst-ventilated public rooms in all London, thanks to its electric lamps. And what is true of this hall is probably true, in degree, of many others.

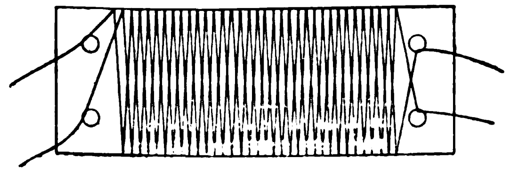
## THE PHYSICAL SOCIETY.

At the meeting of the Physical Society, held on the 12th inst., Mr. Shelford Bidwell, F.R.S., made a communication on

### Some Experiments with Selenium Cells.

Selenium exists in two allotropic forms, the one, vitreous, as structureless as glass, closely resembling black sealing wax, and when in thin films is capable of transmitting ruby coloured light; the other form is amorphous, and exists as a red powder. If left for half-an-hour at a temperature of 200deg. it becomes black. The amorphous variety is a non-conductor. The author observed that it was pretty generally stated in books that selenium in this condition was a good conductor, but this he had not found to be the case; for example, the specific resistance of one specimen, which had been carefully annealed, was as high as 2,500 megohms. When the annealing took place in contact with copper, the specific resistance fell to some 900,000 ohms, and he considered that the diminution of the resistance of selenium cells during the so-called annealing process was due, not to the effect of annealing, but to the formation of a conducting selenide of copper throughout the mass of selenium, beginning at the copper electrode.

The author observed that Willoughby Smith, in the year 1873, first discovered the variation in the resistance of crystalline selenium under the influence of light, and that the name selenium cell was due to Graham Bell. Graham Bell's photophone cells had a resistance of several megohms, and some ten years ago the author had suggested the following modification of Bell's cells in order to diminish this resistance. A strip of mica a few centimetres in length had copper wire wound over it from end to end, the distances between adjacent coils being about one-twentieth of an inch. The wire was wound in two parallel coils, the two coils being carefully prevented from touching each other at any point, and forming the positive and negative electrode respectively.



A Selenium Cell.

Melted selenium was poured on to the strip, and pressed in between the wires. The cell was then kept for some time at a temperature of about 217 degs., and the resistance was found to fall gradually to about 50,000 ohms. The author had made a number of these cells in the years 1880 and 1881, and had noticed that their sensitiveness to light gradually diminished, and in 1882 he laid aside a number of cells until 1885, when the greater number of them were found to be practically insensitive to light. He then (in 1885) laid aside 13 cells until the present year, and of these only one retained its sensitiveness. The resistance of this cell remained as high as 400,000 ohms, while the resistances of the others had all very greatly diminished. The resistance of another one was about 6,000 ohms. This cell was sensitive to light when employed in circuit with a single Leclanché cell; but with a number of cells the resistance broke down, falling to about 100 ohms, the cell at the same time becoming insensitive to light.

The resistances of the remaining 11 cells varied from 4 to 11 ohms, and they were all quite insensitive to the influence of light.

Professor W. G. Adams had found that the resistance of the selenium cells which he had constructed fell in the course of a year to about one-fortieth of their original value, this fall being in all probability due to the formation of selenide of copper.

The author mentioned that the resistance of one of his own cells had fallen in the course of ten years from 80,000 ohms to 10 ohms. In a paper previously read before the Society he had expressed the opinion that the presence of selenide of copper was necessary to the action of the cells, and that this was always formed during the so called annealing process which was found to be essential to make the cells sensitive to the action of light.

It had occurred to him that the effect of passing a strong current through one of his selenium cells might be to liberate selenium more rapidly than it could combine with the copper anode, and to test this he had connected one of the cells with a 26-volt battery. The result of this experiment was the formation of moist red tufts, consisting mainly of amorphous selenium all along the copper wire forming the anode. It was shown to consist of amorphous selenium, by turning black when warmed, and exhibiting the characteristic blue flame of selenium when burned.

The moistness of the tufts seemed greater than was to be expected, simply from the selenium being in the state of a fine powder. The red powder, when examined under the microscope, was found to be mixed with white lumps, which might consist of an oxide, or hydroxide of selenium, but he was not aware whether this was deliquescent.

In the discussion of the author's former paper the late Mr. J. W. Clark had objected to the hypothesis that the diminution of resistance was due to the electrolytic formation of selenide of copper, that in this case the selenide would only be found in the neighbourhood of the anode; but the author considered that it spread from the anode until it extended to the cathode wire. The selenium cells, he pointed out, showed polarisation effects, and developed an E.M.F. under the influence of light, forming photo-electric cells.

The author then exhibited some very striking experiments, to which he did not attach any serious importance, but which he thought were suitable for lecture demonstrations. The usual arrangement of indicating the presence of an electric current by means of a galvanometer and a spot of light is convincing, but not impressive, and might often be replaced by a selenium cell with advantage. A selenium cell was connected up with a delicate relay and electric bell in such a manner that the diminution in the resistance of the cell on exposure to light diminished the current through the relay, and caused the bell to stop ringing.

Different coloured plates of glass were then interposed between the cell and the source of light—a gas-burner—and red, orange, and yellow glasses were found to exert no screening effect, but when a green glass was employed, the light was screened off, and the bell began to ring.

Two blue glasses were then tried, and the light blue was found to exert a screening effect, while a much darker blue did not. The reason of this, as shown by spectroscopic examination of the glasses, was that the dark blue glass, being coloured with cobalt, allowed a good deal of red light to traverse it, but the red light was entirely cut off by the light blue glass. The author suggested that an arrangement of this kind might possibly be employed to ring a bell in case of the extinction of a ship's light or of a railway signal light, or to turn on electric light when daylight falls below a certain point, or apparatus arranged to ring a bell when the cell was exposed to light might be employed in a safe or strong room, and made sufficiently delicate to be thrown into action by the lighting of a burglar's lantern.

DISCUSSION.

Prof. G. M. MINCHIN stated that he had been engaged in the investigation of some of the properties of selenium cells, and a Paper on the subject would be laid before the Society at its next meeting. More attention had, he thought, been given to the influence of light on the resistance of these cells than to its power of developing an E.M.F. in them. The cells which he had constructed gave a considerable E.M.F. when exposed to light; and as an instance of their sensitiveness, he stated that some of his cells developed an E.M.F. of 0·25 volt under exposure to the very small amount of daylight which percolated through the dense fog which prevailed on that day. It had been stated that it was necessary to heat the selenium for a considerable time, and Sir William Siemens stated that the subsequent cooling must also be long continued. He did not find a long continuance either of the heating or cooling process to be necessary, but was able to complete the manufacture of a sensitive selenium cell within 10 minutes. He had not made any experiments on the effect of prolonged exposure to light on the resistance of a cell, but in his experiments on the E.M.F. developed by the cells, and measured by an electrometer, he had found no such deterioration when the cells were kept on open circuit, but there was a deterioration when the circuit was kept closed. He found the maximum E.M.F. to be caused by light from that portion of the spectrum between the yellow and the green, which was in agreement with Mr. Bidwell's results. He had also found that within 24 hours or so of the formation of the cell both the development and the disappearance of the E.M.F. were instantaneous; but after a day or two there was a lagging effect, although the same maximum E.M.F. was ultimately attained.

Mr. MORDEY called attention to the chemical similarity of sulphur and selenium, and pointed out that copper was specially liable to be acted on by sulphur. He asked if other metals had been tried that were not so readily attacked; and, if so, whether it had been found that the deterioration of the cells was lessened.

Mr. PICKERING stated that both the oxides of selenium were deliquescent, and that if the white lumps observed by the author consisted of one of these oxides, they would exhibit an acid reaction.

Digitized by Google

Mr. H. TOMLINSON (in the absence of Prof. W. G. Adams) said that Prof. Adams had employed platinum electrodes in some of his selenium cells, but he was not able to say with what result.

Prof. S. P. THOMPSON had tried using platinum electrodes in his photo-electric selenium cells, but gave it up on account of the high resistance of the cells, which he attributed to a better adhesion between the selenium and copper than between platinum and selenium. With regard to the length of time required for annealing, he stated that it was only necessary to continue the process until the colour of the selenium became slatey grey, and this did not necessarily require any long time. He suggested that the selenium cells might be applied to the regulation of a seconds pendulum with absolute freedom from contact of any kind.

Mr. TRIBE said that in some investigations which he had carried out in conjunction with Prof. Gladstone, and which were described in a Paper communicated to the British Association, they had found a very great difference electrolytically between the two sulphides of copper, and very probably it might be the same in the case of the selenides.

Prof. FORBES, referring to the red tufts which Mr. Bidwell had obtained on the anode, pointed out that Faraday had obtained black tufts of silver sulphide of a similar character on the anode by the long-continued action of a current.

Mr. BIDWELL, in replying, pointed out that there was no doubt that prolonged heating diminished the resistance, and the only question was whether it was due to annealing or to the formation of selenide of copper, as he believed. Prof. Graham Bell had found the resistance of his photophone cells too high when platinum electrodes were employed, and attributed this to imperfect adhesion between the platinum and selenium. It might, on the other hand, be due to the non-formation of a selenide with platinum electrodes and its formation with copper electrodes. He would feel greatly indebted to any chemist who would analyse the material of some of his cells to determine whether or no selenide of copper was present. In reply to a question by Mr. de Tunzelmann, the author stated that though he had made experiments with both copper and platinum electrodes, he had been unable to decide whether the higher resistance of those with platinum was due to imperfect adhesion or to non-formation of selenide, the form of cell employed by him not being suitable for the purpose of deciding the question. He, however, inclined to the opinion that Graham Bell was right in attributing the difference to imperfect adhesion in the case of platinum.

MR. JAMES SWINBURNE read a paper

## On "Alternate Current Condensers."

It is, he said, generally assumed that there is no difficulty in making commercial condensers for high pressure alternating currents. The first difficulty is insulation, for the dielectric must be very thin else the volume of the condenser is too great. Some dielectrics 0·2mm. thick can be made to stand up to 8,000 volts when in small pieces, but in complete condensers a much greater margin must be allowed. Another difficulty arises from absorption, and whenever this occurs the apparent capacity is greater than the calculated. Supposing the fibres of paper in a paper condenser to be conductors embedded in insulating hydro-carbon, then every time the condenser is charged the fibres have their ends at different potentials, and a current passes to equalise them, and energy is lost. This current increases the capacity. One condenser made of paper boiled in ozokerite took an abnormally large current, and heated rapidly. At a high temperature it gave off water, and the power so wasted and current taken gradually decreased.

When a thin plate of mica is put between tin foils, it heats excessively; and the fall of potential over the air films separating the mica and foil is great enough to cause disruptive discharge to the surface of the mica. There appears to be a luminous layer of minute sparks under the foils, and there is a strong smell of ozone.

In a dielectric which heats there may be three kinds of conduction, viz.: metallic, when an ordinary conductor is embedded in an insulator; disruptise, as probably occurs in the case or mica, and electrolytic, which might occur in glass. In a transparent di-electric the conduction must be either electrolytic or disruptive, otherwise light vibrations would be damped.

The dielectric loss in a cable may be serious. Calculating from the waste in a condenser made of paper soaked in hot ozokerite, the loss in one of the Deptford mains came out 7,000 watts. Another effect observed at Deptford is a rise of pressure in the mains.

There is, as yet, no authoritative statement as to exactly what happens, and it is generally assumed that the effect depends on the relation of capacity to self-induction, and is a sort of resonator action. This would need a large self-induction, and a small change of speed would stop the effect. The following explanation is suggested. When a condensor is put on a dynamo the condensor current leads relatively to the electromotive force, and therefore strengthens the field magnets and increases the pressure. In order to test this the following experiment was made for the author by Mr. W. F. Bourne. A gramme alternator was coupled to the low pressure coil of a transformer, and a hot-wire voltmeter put across the primary circuit. On putting a condenser on the high pressure circuit the voltmeter wire fused. The possibility of making an alternator excite itself like a series machine, by putting a condensor on it, is pointed out.

DISCUSSION.

Prof. PERRY said it would seem possible to obtain energy from an alternator without exciting the magnets independently, the field being altogether due to the armature currents.

Mr. SWINBURNE remarked that this could be done by making the rotating magnets a star-shaped mass of iron.

Sir W. THOMSON thought Mr. Swinburne's estimate of the loss in the Deptford mains was rather high. He himself had calculated the power spent in charging them and found it to be about 16 horse-power, and, although a considerable fraction might be lost, it would not amount to nine-sixteenths. He was surprised to hear that glass condensers heated, and inquired whether this heating was due to flashes passing between the foil and the glass.

Mr. A. P. TROTTER said Mr. Ferranti informed him that the capacity of his mains was about one-third microfarad per mile, thus making two-and a third microfarads for the seven miles. The heaping up of the potential only took place when transformers were used, and not when the dynamos were connected direct. In the former case the increase of volts was proportional to the length of mains used, and 8,500 at Deptford gave 10,000 at London.

Mr. BLAKESLEY described a simple method of determining the loss of power in a condenser by the use of three electro-dynamometers, one of which has its coils separate. Of these coils, one is put in the condenser circuit and the other in series with a non-inductive resistance, $r$, shunting the condenser. If $a_2$ be the reading of a dynamometer in the shunt circuit, and $a_3$ that of the divided dynamometer, the power lost is given by $r\,(C\,a_3 - B\,a_2)$, where B and C are the constants of the instruments on which $a_2$ and $a_3$ are the respective readings.

Prof. S. P. THOMPSON asked if Mr. Swinburne had found any dielectric which had no absorption. So far as he was aware, pure quartz crystal was the only substance.

Prof. FORBES said Dr. Hopkinson had found a glass which showed none.

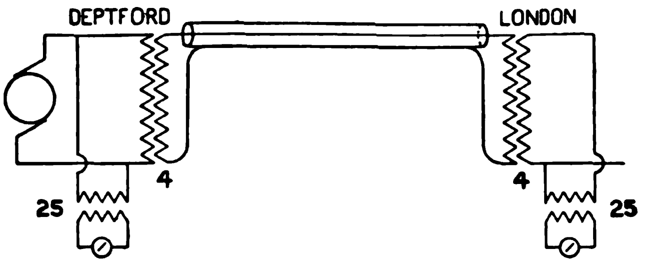
Sir W. THOMSON, referring to the same subject, said that many years ago he made some tests on glass bottles, which showed no appreciable absorption. Sulphuric acid was used for the coatings, and he found them to be completely discharged by an instantaneous contact of two balls; the duration of contact would, according to some remarkable mathematical work done by Hertz in 1882, be about 0·0004 second, and even this short time sufficed to discharge them completely. On the other hand, Leyden jars with tinfoil coatings showed considerable absorption, and this he thought due to want of close contact between the foil and the glass. To test this he suggested that mercury coatings be tried.

Mr. KAPP considered the loss of power in condensers due to two causes; first that due to the charge soaking in, and, second, to imperfect elasticity of the dielectric. Speaking of the extraordinary rise of pressure on the Deptford mains, he said he had observed similar effects with other cables. In his experiments the sparking distance of a 1,400 volt transformer was increased from fifteen-sixteenths of an inch to one inch by connecting the cables to its terminals. No difference was detected between the sparking distance at the two ends of the cable, nor was any rise of pressure observed when the cables were joined direct on the dynamo. In his opinion the rise was due to some kind of resonance, and would be a maximum for some particular frequency.

Mr. MORDEY mentioned a peculiar phenomenon observed in the manufacture of his alternators as bearing on the subject under discussion. Each separate armature coil was tested at a very high pressure, and then, when an armature was completed, it was subjected to double the pressure at which it would be required to work. It was found that the insulation of the armature as a whole could be broken through by a pressure less than that necessary to break through a single coil. This was, of course, easily overcome, but an explanation was not easy to find.

Prof. RÜCKER called attention to the fact that dielectrics alter in volume under electric stress, and said that if the material was imperfectly elastic some loss would result.

The PRESIDENT said that as some doubt existed as to what Mr. Ferranti had actually observed, he would illustrate the arrangements by a diagram.



Arrangement of Transformers between Deptford and London, and small Transformers on Voltmeters. The figures relate to the transforming ratio in each case.

Speaking of condensers, he said he had recently tried lead plates in water to get large capacities, but, so far, had not been successful.

Mr. SWINBURNE, in replying, said he had not made a perfect condenser yet, for although he had some which did not heat much, they made a great noise. He did not see how the rise of pressure observed by Mr. Ferranti and Mr. Kapp could be due to resonance. Mr. Kapp's experiment was not conclusive, for the length of spark is not an accurate measure of electromotive force. As regards Mr. Mordey's observation, he thought the action explicable on the theory of the leading condenser current acting on

Digitized by Google

the field magnets. The same explanation is also applicable to the Deptford case, for when the dynamo is direct on, the condenser current is about 10 amperes, and this exerts only a small influence on the strongly magnetised magnets. When transformers are used the field magnets are weak, whilst the condenser current rises 40 amperes. Mr. Blakesley's method of determining losses was, he said, inapplicable, except when the currents were sine functions of the time, and consequently could not be used to determine loss due to hysteresis in iron, or in a transparent dielectric.

Mr. Swinburne's "Note on Electrolysis" was postponed till next meeting.

## NOTES ON THE CHEMISTRY OF SECONDARY CELLS.*

By Professor W. E. AYRTON, Vice-President; C. G. LAMB, B.Sc., and E. W. SMITH, Associates.

*(Concluded from page 177.)*

DISCUSSION. (AUTHORISED ABSTRACT.)

THURSDAY, DECEMBER 11, 1890.

Mr. S. JOYCE, jun., said he gained some experience with pasted cells when discharged at high rates, and therefore requiring frequent repairs. After several repastings, he found it very difficult to make the red lead paste stick in the positive plates, and then tried litharge paste, similar to that used for negatives. Cells so made had proved very satisfactory.

Mr. D. G. FITZGERALD inquired by what authority and for what reasons the authors called the peroxidised plate the positive, and the spongy lead the negative. He himself had good reason for reversing the designations, and in this he was following the example of Volta and Berzelius. Speaking of the chemical constitution of the negative (peroxide) plate, he said it was generally believed that $PbO_2$ enters largely into its composition; there is, however, reason to doubt whether any of this compound is present, for the behaviour of the active substance on the plates is quite different from that of the pure peroxide of commerce. If a plate be made up of 80 per cent. of pure peroxide and 20 per cent. of the so-called peroxide produced by electrolysis, the E.M.F. falls when the electrolytic product is spent, and the subsequent action of the cell is unsatisfactory. In his analysis of the electrolytic peroxide he had always found some percentage of moisture present, even after it had been dried at a temparature above 212° Fah. He believes the chemical changes produced by electrolysis is represented by the equation $(PbO_2)_{10}, (H_2O)_5, PbSO_4 = (H_2Pb_2O_5)_5, PbSO_4$, and that electrolyic peroxide is $H_2Pb_2O_5$. As regards the best kind of support or grid for the spongy lead, he said it was a mistake to use lead, for copper is in many cases much better. If the copper be left exposed local action takes place, but this is retarded by the addition of any alkaline sulphate. The beneficial effect of soda in secondary cells he attributed to the formation of a double salt, which is easily reduced. Sulphate of magnesium has an extraordinary influence on lead plates, and by using a solution of it as electrolyte he had got discharges 30 or 40 times greater than those obtainable from sulphuric acid. The strength of acid required attention when dealing with heavy discharges. Recently he had used acid having a maximum density 1·252, so that its specific resistance diminished as the cell discharged. In this way, and by the aid of copper supports for the spongy lead, he obtained a comparatively steady discharge of two amperes per pound gross weight of cell for two hours. With ordinary lead grids this would have been impossible.

Prof. PERRY asked if the double sulphate really exists, and Prof. AYRTON inquired whether there were any simple tests by which such sulphates, if formed, could be detected.

Dr. GLADSTONE said Mr. Hibbert and himself had concluded that there was to evidence of double sulphate being formed in the action of secondary cells. He believed the general idea as to the influence of sodium sulphate was that lead sulphate was more soluble in the mixture than in simple acid; this, however, was not confirmed by experiments.

Mr. CROOKES, the new president, said sulphuric acid had a great tendency to form double salts, and thought it very probable that such salts would be formed in the case under discussion. Some results published by Dr. Gore in the *Phil. Magazine* also point to the same conclusion.

Prof. S. P. THOMPSON was interested to learn that, like any other battery, the greatest action occurs at the upper parts of the plates. This might perhaps have been expected, because of its being the path of least resistance; but as the variation of the resistance of sulphuric acid with density is peculiar, and as the denser acid falls to the bottom, the action might have been modified thereby. The details relating to the formation of plates, given in the second Paper, were, he thought, not new, and were practically what any one having a knowledge of the properties of the substances used, and of the reactions which it was desired to bring about, would have arrived at theoretically. For example, to oxidise the positives one would aim at producing the most powerful oxidiser in the shape of ozone, the formation of which is facilitated by strong acid, large current density, and low temperature; on the other hand to reduce the litharge on the negatives it was known that a large current density mainly produces gas, and that production is best effected by small current density at a fairly high temperature. Bearing in mind these opposite conditions, one readily realises that the plates should be formed separately, and that the negatives will require a much longer time. Several years ago he tried cells with electrolytes other than sulphuric acid, and found that phosphoric acid was the only one which gave fairly good results. Speaking of pasted cells Dr. Thompson inquired whether the authors had noticed that the oxidation of the positive paste begins over the grid, and gradually spreads through the mass of the plugs, and whether a useless nucleus remained unacted on in the centre of each.

Replying to Prof. Thompson, Mr. E. A. HALL said he had made experiments on the capacity of cells with plates of different thickness, and found it independent of the thickness. This, he thought, tended to confirm Prof. Thompson's view as regarded a useless nucleus. On the question of acid density he found that the capacity of a cell was increased 15 per cent. by using acid of specific gravity, 1·15 instead of 1·20.

Mr. PREECE rose to correct an error made by Mr. Drake at the last meeting, in stating that the density of acid in the P. and O. battery had been 1·40. Mr. Hall informed him (the speaker) that it had never exceeded 1·22.

Mr. T. FRAZER took exception to the remarks made by Mr. E. W. Smith, in his reply to the discussion at Edinburgh, with reference to the formulæ he (Mr. Frazer) had given for the resistance of cells for different currents, and for the fall of E.M.F. when the charging circuit is interrupted. In spite of what Mr. Smith said, he maintained that his own statements were correct.

Prof. AYRTON, in replying, said the authors greatly appreciated the cordial reception given to the Papers by practical engineers, for one of the aims of the Central Institution was to train students to do work and carry out investigations the results of which would be of commercial value. Referring to Dr. Gladstone's criticisms about the ammonium acetate method, he said that Mr. Robertson had used this method, but somehow or other the paragraph describing it had not been printed in the first proof. Speaking of measuring the resistances of cells, he pointed out that unless the curve

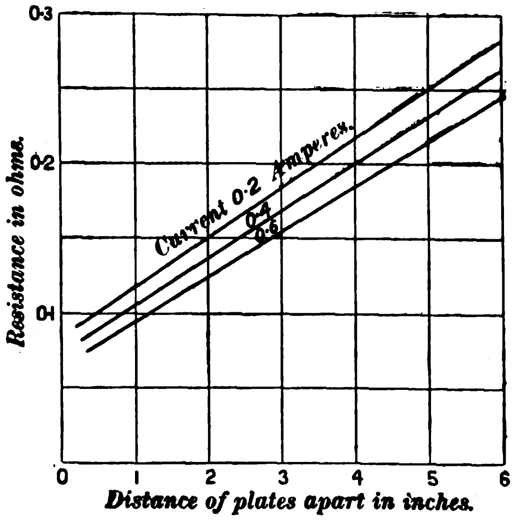


DIAGRAM A.—Resistances of Small Secondary Cell. Plates 4¼in. by 2¼in.

connecting time and E.M.F. was discontinuous at the instant of breaking circuit, the method used should give correct results. So far as he knew there was no evidence of any such discontinuity. Mr. Crompton had said the resistance was practically independent of the distance of the plates apart, and that the sulphating of the negatives during rest depended greatly on light. Taking the case of resistance first, they had made experiments on a small two-plate cell, and found that when the ordinary method of testing was employed, Mr. Crompton's statement seemed nearly correct, but on using the more sensitive method illustrated in Figs. 10 and 11 of the Edinburgh Paper, this was not the case. Diagram A represents the results of these experiments. To investigate the effects of light, darkness, and sulphate of soda on the liberation of gas from idle negatives, they had experimented on three similar E.P.S. cells. The fully charged negatives, designated by A, B and C respectively, were put in three different vessels of acid, one of which contained 0·8 per cent. of sodium sulphate and the gases collected. A powerful arc light illuminated one set of plates, whilst the others were kept dark. Plate A, when illuminated, gave off gas very rapidly, whilst B and C in the dark produced very small quantities which were about equal. On interchanging the plates, however, it was found that neither light or sodium sulphate had any marked effect on the rate at which gas was given off, for whether A was illuminated or kept dark, or put in ordinary acid or in the sodium sulphate solution, gas was liberated rapidly at about the same rate, whilst B and C were equally inactive under all the conditions. They therefore conclude that the rate at which gas is liberated depends on some peculiarity of the plates themselves. Some speakers, he said, had remarked that many of the facts brought forward in the papers were previously known. To this he replied that none of the facts given as new were known to the authors before they discovered them experimentally. Manufacturers might have been aware of them, but if so, they had kept them secret and never published them. For example, Dr. Gladstone, one of the highest authorities on secondary cells, was not aware of the differences in the hardness of the plugs at different parts of the plates until the appearance of their paper. Another case in point was the fact that Dr. Thompson said there was nothing new in the methods of forming the plates, whereas Mr. King apparently did not know of them. Mr. Swinburne had also called their attention to a prediction of the cooling of cells during discharge made in

* Paper read before the Institution of Electrical Engineers on Thursday, November 13, 1890.

Digitized by Google

1887, but at that time he admitted that he had not observed it. Speaking of the efficiency of cells, he said some people think the very perfect testing apparatus gave the cells their high efficiency; this of course was not true, for their figures merely express the results obtained when cells are used in a proper manner. Referring to a criticism on the Edinburgh paper which appeared in one of the leading technical papers of July 25th, he said the writer had only partly understood the early part of the paper, for they (the authors) had there explained that one of the objects of the investigation was to see what error could be made by neglecting the previous history, and the resuscitating power of cells. The same writer had also stated that the results of laboratory tests were not applicable to ordinary working conditions. Here, again, he had fallen into error, for a secondary cell is a thing complete in itself, and if two or three selected at random give good results under proper treatment, so any number, if similarly treated, will show equal efficiency.

## EXPERIMENTS ON THE MAGNETISATION OF THIN PLATES OF STEEL AT RIGHT ANGLES TO THEIR PLANE.*

BY W. DOULE.

The plates experimented on were squares (the side being from 10 to 20mm. in length), rectangles of various sizes and circles, cut from springs from 0·25 to 0·3mm. thick, or from sheets 0.35mm. thick. They were magnetised by means of two thick bobbins of 8,000 square centimetres surface, through which was passed the current from a dynamo. In order to produce an anomalous magnetisation, the current was gradually reduced by the insertion of resistance, as suggested by Von Waltenhofen.

The discs were first suspended by a silk fibre in order to determine the position they took up with regard to the magnetic meridian. Magnetic figures were then produced by sprinkling iron filings on a thin sheet of paper, and the spot indicated as poles by the arrangement of the filings were investigated with a small compass-needle 4mm. long.

For all the specimens tried, a magnetisation at right angles to their plane seemed to be impossible. Two poles always appeared, and they were so arranged as if, in the case of the squares, the magnetising force had acted along a diagonal, and in the case of the rectangles, parallel with the longer side.

When 80 square plates 0·25mm. thick and 10mm. length of side were placed together so as to form a square prism 20mm. long, and magnetised, the iron filings showed a perfectly regular distribution of magnetism, similar to what occurs in a solid magnet. As soon, however, as they were separated, the individual plates were found to be magnetised as above mentioned.

A series of steel cylinders, 22mm. in diameter, and of lengths varying from one to 20mm. were then experimented on. They were of Bessemer, tool, and manganese steel, and were supplied by Dr. M. T. Edelmann. Cylinders of a height of 10mm. and more showed a perfectly defined magnetisation in the direction of their axes. As the height was reduced the polar axis became more and more inclined to the geometrical one, until, at a thickness of 1mm., the same state of affairs as was observed with the thin square plates occurred.

It would therefore appear to be in the highest degree probable that a permanent magnetisation of thin steel plates at right angles to their planes is impossible when the ratio between their thickness and their other dimensions becomes reduced below a certain value.

## AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *December* 5, 1890.

**The Subway Question in New York.**—The subway situation is not in the way of immediate improvement. At a recent meeting of the Board of Electrical Control a specious proposition came in from the Company that has been put in charge of subway installation by the present City Authorities, announcing that a new subway company had been organised by persons interested in various telegraph and telephone companies, under the name of the Empire City Subway Company, and suggesting that the low-tension work be turned over to them. What the electrical companies are now interested in finding out is the scheme that in all probability lies under this plausible proposition. The relations between the new company and the present one remains to be determined, but it appears to be altogether too harmonious to augur much good to those who desire subway accommodation. Mayor Grant continues his old threat of lighting the streets by gas unless the electrical illuminating companies will furnish street-lighting at practically the old rates. In a word, the situation is this: the company that is permitted to put down subways is allowed to charge rentals that are nearly prohibitory. Owing to the extortionate prices demanded for subway accommodation, the electric light companies have raised their prices, and the Municipal Authorities are now trying to compel them to use the subways by threats of dispensing with electric light altogether.

**A Curious Lightning Accident.**—An interesting accident was recently reported on one of our electric street railways. It occurred during the past summer. The electric line in question has rather severe grades produced by series of ridges over which the road passes. During a severe thunderstorm lightning struck the trolley wire at a time when three of the cars were descending grades with the current cut off. The other cars were running on a level or up-grade. Each of the cars running down grade by gravity suffered the loss of a field coil. The others, although in quite as exposed a position, were uninjured. In every case the damage to the field was produced by the lightning piercing the insulation and jumping to the core of the magnet. The explanation seems comparatively simple, for the road in question was on the Sprague system, in which the field coils are wound in three sections, and even when the motor is not in use, one of them is energised. This energised coil was the one damaged in each case, the lightning passing into it and through into the core, while in the moving cars with the field magnets fully magnetised, the self-induction was sufficient to choke the lightning discharge, so that it did no damage. It was, it seems, a very pretty example of a coil of high impedance checking lightning discharge. The superintendent of the road averted the probability of a similar accident by changing the motor connections, so that the field coils would be cut off at the switch-box instead of one of them remaining connected.

**Electric Traction on the Chicago Elevated Railway.**—It is now reported that one of the elevated railroads that is to be built shortly in Chicago will adopt electricity for a motive power. The arrangements have not yet been made, but the company is in negotiation with several electrical companies concerning the equipment of the proposed road. There is every reason to believe that electric power will find its way into more than one of the new elevated systems of this country, for it is now evident that such an application will be a success.

**Storage Battery Traction.** — Storage battery traction is active just now, not less than half a dozen small companies having experimental cars in various stages of progress. It is to be noticed, however, that very few storage battery cars are operated by street railway companies quite independent of the company furnishing the battery, and the small number of cars that are independently operated have not, as a rule, given very great satisfaction. The feeling is strong among electricians that something radically new in the storage battery line must appear before electrical traction by this means can be made commercially advantageous.

## CORRESPONDENCE.

### EXPERIMENT WITH A CONDENSER AT DEPTFORD.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: On the day after our last meeting of the Physical Society I saw at Deptford, in a test by Mr. Ferranti of a vulcanite tray subjected to 20,000 volts (square root of mean square), a most interesting illustration of one of the subjects discussed in connection with Mr. Swinburne's Paper. The tray was rectangular, with rounded corners and edges, and may have been 8in. or 10in. long, by 5in. or 6in. broad, and 1½in. deep (I write from memory). The vertical sides ended in a flat lip, about 1in. broad, projecting horizontally on all sides. It was laid on the bottom of a large metal tray filled with

* *Wiedemann's Annalen*, Vol. XLI., Part 10.

Digitized by Google

water, and was filled up inside to a depth of about half an inch. During the test we observed a blue line of light all round the water-line, both inside and outside, which seemed to be everywhere about a quarter of an inch broad (we did not apply a ruler or compasses to measure it!). When the test was completed and the electrification stopped, we took the tray out and looked at it carefully all round. We found, as we expected, that there was no sign of perforation, but we saw a very remarkable appearance all along the lines, inside and outside, which had been the boundaries of the water. They showed, at regular intervals, little vertical marks; the explanation of which was, no doubt, capillary standing waves produced in the water by the electric force, and analogous in hydro-kinetic and capillary quality to the ripples seen inside a finger-glass caused to sound by a wetted finger drawn along its rim. The blue light which we saw was, of course, due to the same cause as the well-known sparkling at the edges of the coatings of a Leyden jar when suddenly charged or discharged. The sparkling described by Mr. Swinburne in his mica condenser was no doubt due to the same cause. When the breadth of a band of sparking round the edge of a metallic coating is considerable in comparison with the linear dimensions of the coating in any condenser subjected to rapidly alternating high potential, there must be considerable heating due to it; and the mere fact of heating would not prove that any sensible proportion of the heating is due to viscosity of electrostatic inductive capacity.

An internal sparkling or quasi-sparkling in some of the ingredients of heterogeneous insulators may be the cause of some of the heating of condensers which has been observed by Mr. Swinburne and others.

Recurring to the subject of duration of contact between two mutually impinging metal balls, we must not assume that this is the duration of electric conductance between them. On the contrary, when the potential of the charge is several thousand volts, there might be separation to the extent of a millimetre or two without cessation of very effective electric conductance. But it will be interesting to find whether, with charges of one or two volts, the exceeding shortness of the duration of metallic contact of mutually inpinging balls can suffice to let us sometimes find the electrification of a condenser reversed, after a discharge by impact, even in cases in which the period of the oscillatory discharge with constant resistance is only a few ten-thousandths of a second.—Yours, truly,

WILLIAM THOMSON.

The University, Glasgow, Dec. 15, 1890.

## FORCES BETWEEN CURRENTS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In the note with which Dr. Lodge kindly prefaces my letter which you were good enough to insert in your issue of December 12th, he remarks that the stresses I notice have their analogies in electrostatic actions. This is undoubtedly the case with those depending on the pressure normal to the direction of the flow; but I think he will allow that the shearing stress due to tangential force on the sides of the tunnel seems more like an electro-magnetic effect.

The pressure normal to the tunnel, like the electrostatic action of a current, does not in all cases produce repulsion. In fact, in most cases the action is an attraction by which two cavities containing fluid at different pressures tend to move towards one another, if one of the pressures be less, and the other equal to or greater than that on the surface of the block.

The action of the shearing stress is quite different; it must always cause a push between contrary parallel currents, never a pull, and is thus, though in itself mechanical potential, more like electro-kinetic stress. Also, granting that Sir William Thomson's vortex ring theory of matter may be correct, must we not consider the molarly potential energy of mechanical stress to be molecularly kinetic?

Since my letter was written I have learned that Sir William Thomson has shown that the distribution of stress in the medium surrounding a magnet is the same as that in a jelly distorted by a torque applied to a rigid bar embedded in it. I think this justifies the idea that electro-kinetic actions may be likewise represented.—Yours truly,

JAMES ERSKINE MURRAY.

40, Montgomerie Drive, Glasgow, 14 December, 1890.

[Two or three years ago, while considering from a merely geometrical point of view some of the different displacements to which the ether might be subjected, we constructed diagrams

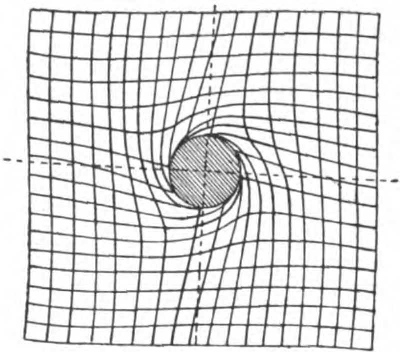

FIG. 1.—Strains set up in a Jelly by a Torque applied to a Cylinder. Twist through 45 deg.

showing the strains set up in a jelly by a torque as described by our correspondent. We herewith reproduce three of these, which present several points of interest, showing a tendency to

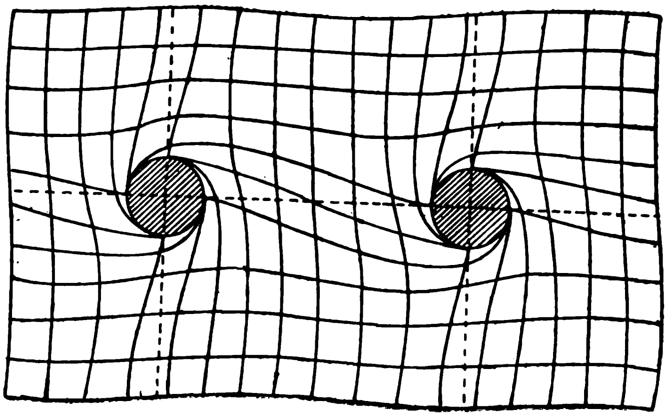

FIG. 2.—Cylinders twisted in same direction through 45 deg.

attraction and repulsion. The outline of Fig. 1 resembles that of a square bar subjected to a torque (*see* Perry's "Practical Mechanics," p. 98). The same outline is to be seen in Fig. 2,

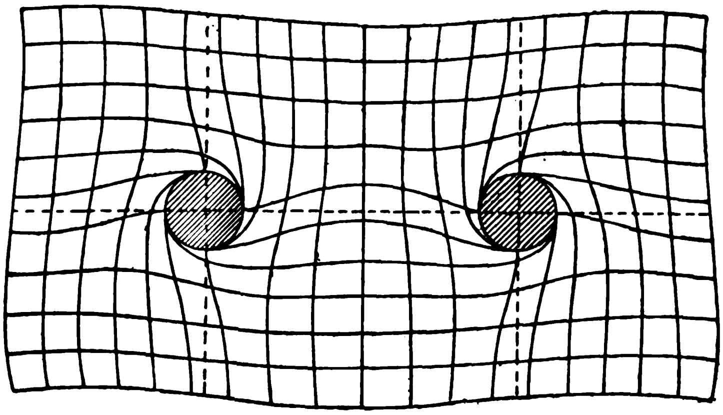

FIG. 3.—Cylinders twisted in opposite directions through 45 deg.

there being no tendency to alter it; but in Fig. 3, the two stresses being in opposite directions, the middle transverse line is straight, the upper part of it passing through a region of great compression, and the lower through a region of extension.—ED. *E.*]

## TENDERS FOR MULLINGAR ASYLUM.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: Being greatly interested in the electrical engineering industry and its progress in Ireland, I naturally follow with keen interest any new development of the same over here. I was very much surprised and perplexed to notice in your this week's trade notes the material financial difference in the various tenders sent in for installing the electric light in Mullingar District Ayslum, and I absolutely fail to see how this can be satisfactorily accounted for. Taking the highest and lowest tender, there is the immense difference of £1,958, more than double the amount of the lowest tender (£1,755), both of them being London firms. Am I to understand that the Electric Engineering Corporation are prepared to carry out the same amount of work with the same class of goods and efficiency as Messrs. Siemens Brothers and Co. If this difference is the rule with all estimates these two firms are furnishing to intending clients, and presuming each have their share accepted, it will be very interesting to note and compare their individual profit and loss accounts when next audited. If one of these firms are manufacturers, and the others merely agents or warehousemen, some slight difference might be accounted for; but this, I believe, is not the case, both of them being manufacturers. There is little doubt that, were these the only two tenders sent in, the Commissioners would have little difficulty in deciding. Surely the business side of the electrical science has reached a higher stage of perfection in estimating than this unexplainable difference would indicate. Even the two Dublin firms who have furnished tenders show a difference of £715, which I should say would be a very handsome profit, presuming the higher tender be accepted.

Evidently the maxim, "small profits and quick returns," is not that closely followed by all electrical firms. Perhaps it is to the Commissioners' decision and the subsequent carrying out of the work that we must look for the solution of this problem.—Yours, &c., Arthur O'Brien.

Dublin, December 15, 1890.

[This is largely a question of specification. It would be much more interesting to compare two jobs when completed, according to the highest and by the lowest tenders, than to compare the profits. The specification was not short, but it did little but enumerate the items. Specifications for electrical work are as yet very much more vague than in other branches of engineering. A strictly-drawn specification, while it leaves but little room for divergence, will necessarily raise the average price by reducing the number of chances which a contractor has for introducing his own manufactures or specialities. After all, the best specification is but little protection to the purchaser without the additional services of a consulting engineer.—Ed. *E.*]

## ELECTRICAL TREATMENT OF SEWAGE.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: I have been much interested in reading the abstract of Mr. Webster's Paper on "The Electrical Treatment of Sewage," published in your impression of last week, the more so because, when in Manchester last May, I took the opportunity of visiting the experimental plant erected by both the "Electric" and the "International" Companies; and by the courtesy of the gentleman who represented the Salford Corporation during the trials then just on the eve of commencement, I was enabled to see all but the work of purification in actual operation.

I was particularly struck by the extreme simplicity of the "International" plant as compared with that required by the Electric Company; on the one hand a sluice, into which "ferozone" is automatically fed and mixed with the flowing sewage, precipitating tanks, and polarite filters, on the other, an engine and boiler, dynamo and copper leads to the electrolytic conduit and sand filters.

It appeared to me, as an engineer, that provided equally good results were obtained in both cases, there could not be any hesitation in deciding which would give the least trouble in practice, more especially as the International process has been at work with success at Acton for the past three years.

What seemed to me strange was how the electrolytic conduit, consisting, as it does, of a large number of cast-iron plates, half an inch thick and ⅝ of an inch apart, could successfully treat the class of sewage often obtaining, namely, dead cats, rats, old boots, lumps of cotton waste, and kindred substances always met with in the sewage of a manufacturing district. Should it become necessary to strain all the sewage prior to allowing it to flow into the conduit, this would introduce a not inconsiderable item in the required plant, and in the cost of maintenance, which does not appear to be considered in the abstract you published.

You have rightly criticised the estimated cost of the requisite power set forth in the paper, and you have shown in your notes that on the evidence of the results, namely, 0·37 ampere-hour per gallon of sewage treated, the annual cost of producing the required electrical energy under the conditions stated in the paper would be something like £8,500 to £9,000 to treat ten million gallons of sewage per 24 hours.

You have further drawn attention to the fact that at the rate of consumption of iron claimed by the Company, namely, three grains per gallon, the cost of iron alone per year at £4 per ton would be about £2,500.

But what you have not pointed out, and what appears to me to be a most important point is this: that the plates cannot be used up to the last grain, for two reasons. As the plates get thinner the electrical resistance of the conduit would be much increased, and not only would more power be required to produce the necessary electrolytic effects under normal circumstances, but the state of things would be aggravated by some of the more liquid sewage flowing past, owing to the increased space between the plates, without being properly treated. It is therefore justifiable to anticipate that the consumption of iron, as well as the power required, would in practice work out to a higher figure than that mentioned in Mr. Webster's paper for the given degree of purification.

Since cast-iron at £4 per ton cannot be relied on as being very homogeneous in its texture, it is reasonable to suppose that the plates would not wear uniformly, but would tend to wear "in holes." It would, for this reason as well as for the above-mentioned, namely, the increased electrical resistance due to increase of space between the plates, not be wise, I take it, to allow the plates to wear to less than half their original thickness. Thus it would appear that another item, namely, frequency of renewals, have been overlooked.

There is just one more point which struck me as not being sufficiently detailed in the report of Mr. Webster's Paper, and that is the nature of the trials. Sewage, as is well-known, varies in quality sometimes very rapidly, generally according to the time of day or night. Now there is no evidence, as far as I can gather, that the power developed by the engine, or the electrical output, over any period was compared with the analysis of the sewage during that time and with the quality of the effluent of the sewage treated during that particular period. Nor is there any evidence that the degree of purification found by Sir H. Roscoe in previous experiments was realised in this case with the above-mentioned consumption of iron, namely, three grains per gallon. There is too much averaging, too much generalisation. The results may, of course, be perfectly accurate, but they may be quite misleading. The results of any tests or trials should always be given in such a manner that the method by which the average result is obtained is quite clear, so as to enable every one to form their own opinion as to the value of the average result for the purposes at issue.

Trusting the importance of this question may be some excuse for my having trespassed at such length on your valuable space, I remain, yours faithfully, Ed. C. de Segundo.

Whitehall Club, December 16, 1890.

## ELECTRICITY FOR HEATING PURPOSES.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: The subject of evaporating water and concentrating liquors by means of electricity is an interesting one to the manufacturing world, though I can find very little information on the matter in the most recent publications on electrica

Digitized by Google

science. In places where fuel is scarce and water-power is available, it is sometimes desirable to use heat for raising steam or evaporating, or even in localities where there is available fuel and a good water-power, it might be cheaper and preferable to use water-power. At any rate, the case I have in view is a borax marsh in California, near which place there is a waterfall of fully 500 feet. This fall can be utilised by the means of a Pelton water-wheel to drive a dynamo; and what I want to ask any of your readers through your medium, if I may venture to do so, is this:—

Has any method been devised of boiling water by electricity? If so, by whom? and where can I obtain particulars?

It has been suggested that a coil of wire circulating round an iron pipe will induce a certain amount of heat, and that the temperature of water passing through a pipe so arranged will be raised to the boiling point. If that be so, then the arrangement can be made applicable to manufacturing industries, and you can make a waterfall boil a pan of water, not to mention the great convenience it would be in domestic life where the current is laid on to a house for lighting, and power to have it available for hot water as well.—Yours, &c.,

E. L. Fleming.

19, Shaftesbury-road, Ravenscourt Park, W.

[Our correspondent further informs us that fuel is very scarce in the country referred to, and that he considers that 150 horse-power would practically cost him nothing. With this power he might, with perfect machinery, raise some 3,000 gallons 200deg. Fah., or might evaporate some 630 gallons in 24 hours; but in practice he could hardly expect to heat up and boil away as much as 400 gallons. As it would take nearly a ton of wood to do this, there may be something in the scheme which does not at first sight appear to be hopeful.—Ed. *E.*]

## TRADE NOTES AND NOTICES.

*[Notices for insertion under the above heading must reach the Office not later than first post Thursday morning.]*

Tender Wanted.—Tenders are invited up to December 23rd, at the Ministerium der Colonien, for the supply of iron telegraph posts (Henley system), iron insulator stems, and galvanised wire.

Electric Lighting Contracts.—We would remind our readers that the tenders for the electric lighting plant required by the Pretoria Lighting Company (Limited) must be sent in to Mr. A. Moir, the London Secretary of the Company, 29 and 30, Holborn-viaduct, E.C., by noon on December 20th. Mr. Moir will supply all particulars.

The Expiry of Telephone Patents.—Mr. G. A. Nussbaum, C.E., desires us to state that he has been appointed sole agent in this country for the Société Générale des Téléphones, who are the owners of Ader's patent telephone magneto transmitters and receivers with battery call.

The Electrical Supplies and Fittings Company (Limited.)—We are in receipt of an intimation from the Globe Electrical and Engineering Company that the business of that Company has been transferred to the Electrical Supplies and Fittings Company (Limited), by whom a complete catalogue of electrical supplies is in course of preparation.

Messrs. Mori and Moorhouse.—We have received from this firm a fully-illustrated catalogue and price list of their specialities, including electric bells, indicators, wood, china, and brass pushes, burglar and fire alarms, wires, &c. The catalogue is noticeable for its well-designed frontispiece.

Anglo-American Telegraph Company.—We have received from this Company a useful blotting pad and calendar for 1891-1892.

Mr. F. W. Ness.—Mr. Ness sends us from Montreal a well got-up catalogue of electrical apparatus. The catalogue contains, in addition to the apparatus and machines usually to be found in a trade catalogue, some humorous illustrations on the subject of overhead wires.

## COMPANIES' MEETINGS & REPORTS.

### The Gulcher (New) Electric Light and Power Company (Limited).

The third ordinary general meeting of the Gülcher (New) Electric Light and Power Company (Limited) was held at Winchester House, Old Broad-street, yesterday (Thursday), under the presidency of Mr. D. de Castro.

The SECRETARY (Mr. T. C. Morgan) read the notice convening the meeting, and the minutes of the previous meeting, which were confirmed.

The CHAIRMAN said that the past year had been a very important one for the Company. On June 30, 1889, they had a very small Preference capital, which consisted of 12,277 shares, and they had at that date £10,000 Second Mortgage Debentures, to which they had to add another £6,000, which they were obliged to raise in order to meet the extraordinary difficulties in which the Company was placed by the contract they had entered into in New Zealand. This year he was happy to say that things were in an entirely different condition. They found that however prosperous the Company might be, or whatever might be its prospects, it was hopeless to expect that, having so small a capital, and being burdened with such heavy mortgages—£16,000, bearing the large rate of interest which they were obliged to pay before they could raise the money at all—it would be impossible to declare a dividend. He represented the case to some of their friends and supporters and the Board, and they agreed that their only course was to propose an issue of the balance of their capital, and to pay off these Debentures, which were absorbing all their profits. Accordingly, in the beginning of last year they issued the balance of their Preference capital, and he was happy to say that the whole of the amount had

Digitized by Google

been subscribed very largely by those who held the Ten per Cent. Debentures. The capital, therefore, now stood at £50,000 Preference shares of which £30,797 was paid up on June 30th, and he might tell them that at the present moment they had not only redeemed all their Ten per Cent. Debentures, with the exception of £200 held by one gentleman who declined to be bought up, but they had the handsome capital of £50,000 subscribed, and an uncalled capital exceeding £13,000. He thought that they would all admit that this was a position which neither the old nor the new Company had ever attained before. The business which had plunged them into difficulties in the infancy of the Company was the undertaking by mistake on the part of their late Manager of a contract in New Zealand, which had cost at least six times what it was estimated it would do. The original estimate of their engineer was £2,500, whereas the contract referred to had cost the Company £13,500. This was, even under their altered circumstances, a very large share of their capital to have locked up in what was not properly the business of the Company. They were a manufacturing electrical engineering company, not a supply company, which required a very much larger capital than a Company like theirs. The capital of £13,500, left alone, would not pay. It would not produce an income proportionate to the outlay, even if they consented to have it locked up, and to make it pay it would be necessary to lay out at least another £9,000 or £10,000 in order to produce a substantial interest upon the £25,000 or £26,000 which would then be invested there. It became, under these circumstances, a matter for the consideration of the Board whether they should lock it up, or a substantial part of it, and again leave themselves with very little free money. They decided in the early part of the year that if they could possibly avoid doing so to any substantial extent they would, and at the suggestion of his colleagues he had been since quite January 1st engaged in forming a syndicate, who, as was stated in the report, would provide for the private supply of the town of Wellington, and not only that, but would ultimately take over the Company's business in New Zealand, together with the benefit of the contract for the public lighting, entered into between the Company and the Mayor and Corporation of Wellington. That syndicate had been at last formed, and £10,000 had been subscribed, of which this Company would, at the most, have to risk £2,500 of their spare capital. He hoped, therefore, that when he met them again next year they would be able to report not only the completion of their contracts, but of the work which would be done by the expenditure of this money, and the receipt of a revenue which would enable them to declare a substantial dividend upon the whole of the capital of this Company. Another advantage to be considered was this. They were, as he had said before, a manufacturing Company, and this syndicate, which would probably grow into a much larger concern, would be a supply Company, and, *cæteris paribus*, he thought there could be no doubt that if the articles the Company sold in New Zealand continued to hold the position they now did there, the syndicate would become a very valuable customer to the Company, so that both directly and indirectly they would be gaining by the transaction. They thought it would be well, having regard to the tendency of electric lighting to run into independent installations that they should have an interest in the lighting of some district. While London was being apportioned out among the great companies, they thought, if they could see their way without material expenditure, to get a company registered, which would secure, or tend to secure, the preference, if not the monopoly of a district, it would be wise in the interests of the Company to secure that at an outlay of about £100. Accordingly, they had got a share in "The South Western District and Thames Valley Electricity Supply Company (Limited)," which had been registered, and he had received promises of support from established customers in the immediate neighbourhood of that Company's district. He was grieved to say that there was no net profit to show. The gross manufacturing profits for the year ended June 30, 1890, amounted to £3,097, and never since the Company was formed had they reached a third of that figure. But owing to the difficulties he had mentioned, they had made a loss last year of £1,417. Therefore they had been trading at an advantage of £4,503 over the previous year. The heavy interest payable on the Second Mortgage Debentures had been the real reason why they were unable to declare a profit, a circumstance which would not occur again. But for that they might have been able to declare a dividend of fully 3 per cent. Next year he thought that they might fairly anticipate being able to divide that and possibly more. He might mention that he was about to proceed to New Zealand to see if he could obtain powers, not only for lighting Wellington, but other places in the Colony. Having referred in detail to the various items in the balance-sheet and profit and loss account, he said that the Company had made arrangements for charging steam launches from their works on the river. This was a growing business, from which they anticipated good results. Their Mr. Fricker had also designed two very excellent little dynamos for the purpose of supplying houses, requiring from 20 to 50 lights, not within the district of any supply company. The same gentleman had also constructed a motor which would work during the daytime from those dynamos, and would do the work of small gas engines, or drive any small machinery that might be required. The dynamos were called the "Hercules" and the motor the "Midget," for both of which there was evidently going to be a considerable demand. Next week the instruments might be seen at work in a show-room at 139, Queen Victoria-street. They anticipated great advantage from these two branches of business next year, and a branch that was far more important than either—and far more important in his opinion than even the electrical business of New Zealand—was this. They had made a contract with the only people that he knew of who had been able hitherto to weld steel and cast iron with success where large castings were concerned, by which contract the Company would have a monopoly of the supply of the machinery, from which they anticipated great benefits to the Company. They had been lighting for the past two years the Spanish and French Exhibitions, and on the previous day he had succeeded in securing the lighting contract for the German Exhibition next year. He concluded by moving the adoption of the report (which appeared in our last issue) and accounts.

Mr. H. GREWING seconded the motion, which, after a short discussion, was carried unanimously.

The retiring Directors, Mr. De Castro and Mr. Hilton were afterwards re-elected on the motion of Mr. HARTON, seconded by Major COTTON, as was also the auditor, Mr. Russell Day, on the motion of Mr. LAMONT, seconded by Mr. OHMAN.

A vote of thanks having been passed to the Chairman and Directors, on the motion of Major COTTON, seconded by Mr. HARTON,

The CHAIRMAN briefly returned thanks, and the proceedings terminated.

## Western Counties and South Wales Telephone Company (Limited).

An extraordinary general meeting of this Company was held on Friday, at the Grand Hotel, Broad-street, Bristol, Mr. Charles Nash presiding.

The following report is from the *Bristol Mercury* :—

The SECRETARY (Mr. Henry F. Lewis) having read the notice convening the meeting,

The CHAIRMAN moved the adoption of the following :—

"*That the Directors be, and they are hereby, authorised by this general meeting to borrow any further sum or sums of money, on such security (but not so as to prejudice existing Debentures) and terms as to interest or otherwise as they may deem fit, and to secure the same by debentures upon the whole or any part of the property, funds, assets, or effects of the Company, and so that any sum not exceeding* £80,000, *including the* £50,000 *previously*

PATENT

SILICIUM BRONZE AND SILICIUM COPPER WIRE.

*authorised and issued, may be owing at one time, but so that the money to be borrowed under the authority of this resolution or consent shall not bear a higher rate than 6 per cent. per annum, nor, without the consent of the National Telephone Company (Limited), a higher rate than 5 per cent. per annum.*"

He would say a very few words upon the progress of the Company's business during the present year. The number of subscribers to the exchange and to the trunk lines in 1885 was 779 ; in 1887 it had increased to 2,034, and in November, 1890, it had increased to 3,540. As to receipts, after the payment of royalties, they had increased from £8,064 in 1886 to £21,286 in 1889, and, judging from the progress made during the present year, he had no doubt that the amount for 1890 would exceed £26,000. It was also satisfactory to find that the increase was going on at a more rapid ratio than it was last year. In 1889 the increase in the business was at the rate of £325 per month ; during the present year the increase had been at the rate of £411 per month, so that the increase on that of last year had been at the rate of about £1,000 per annum. All that had required capital to be expended, and that was the reason of the proposal now to issue £30,000 on Five per Cent. Debentures. He need not say much about that. They believed the security was an excellent one. The surplus remaining last year, after paying interest on existing debentures, was £6,848. The surplus this year would certainly be very much larger, and the interest upon the debentures now proposed to be issued would be only £1,500, so that it appeared to the Directors that the security offered was a very excellent one.

Mr. READ seconded the motion. He remarked that the progress of the Company's business was satisfactory to the shareholders in every sense.

In reply to a question as to the expiration of certain patent rights at a future period, it was stated that the Company were covering their district so well that there would be little or no room for any competing company.

The motion was unanimously adopted.

## NEW COMPANIES REGISTERED.

**FOREIGN ELECTRIC DATE AND TIME STAMP COMPANY (LIMITED).**—Registered by F. Fearon, 25, Parliament-street, S.W., with a capital of £100,000 in £1 shares. Object: To acquire an invention of an electro-mechanical date and time stamp, for which patents have been obtained under the patent laws of France and Italy, numbered respectively 188,735 and 26,337.

**GLASS AND METAL ENGINEERING COMPANY (LIMITED).**—This Company has been registered in Glasgow, with a capital of £5,000 in £1 shares. Amongst the objects are the use of all kinds of processes in the art and business of electroplaters.

**LONDON METALLURGICAL COMPANY (LIMITED).**—Registered by Payne and Lattey, 24, Cornhill, E.C., with a capital of £15,000, in £10 shares. Objects: To acquire any patents, brevets d'invention, licences, &c., which may seem capable of being profitably dealt with.

**NEW YORK BELTING AND PACKING COMPANY (LIMITED).**—Registered by Parker, Garrett, and Parker, St. Michael's Rectory, Cornhill, E.C., with a capital of £426,000, in 22,500 Preference and 20,000 ordinary shares of £10, and 1,000 Founders' shares of £1 each. Object: to carry into effect, with or without modification, an agreement which has already been prepared, and is expressed to be made between the New York Belting and Packing Company, a Company organised under the laws of the State of Connecticut, United States of America, and this Company, to carry on the business heretofore carried on by the said American Company, and to carry on, as principals or agents, the manufacture and sale of indiarubber and other goods of all descriptions, and such other businesses as may be necessary or expedient to be carried on for the purpose of developing the business to be taken over under the agreement referred to, or any branch thereof, and for such purposes to acquire lands, works, property, and premises wherever convenient, machinery, patent rights, &c. The first subscribers are: Messrs. A. Vaughan-Stevens, J. C. Wylde, P. J. Bordessa, W. Tunstall, E. H. Tuthill, H. B. Bourne, and F. Spooner.

**SHETTLESTON OIL AND CHEMICAL COMPANY (LIMITED).**—Registered in Scotland, this Company has a capital of £5,000, in £10 shares. Objects: to take over, carry on, and develop the coal tar or chemical works, or carbonising works, carried on at Mount Vernon, Lanarkshire, and to carry on the business of chemical manufacturers, miners, smelters, colliery proprietors, engineers, ironmasters, ironfounders, and manufacturers of products of every description from minerals, and dealers in such products and minerals.

**J. TYLOR & SONS (LIMITED).**—Registered by Sydney Morse, 4, Fenchurch-avenue, E.C., with a capital of £100,000 in £10 shares. Object: to carry on business as mechanical and consulting engineers, sanitary engineers and contractors, &c., manufacturers of electrical plant and apparatus.

## CITY NOTES, &c.

**BRAZILIAN SUBMARINE TELEGRAPH COMPANY.**—The receipts of this Company for the week ended December 12th amounted to £5,282.

**CROMPTON AND CO.**—The Directors of this Company have declared an interim dividend on the Preference shares for the half-year ended September 30th last at the rate of 7 per cent. per annum.

**EASTERN TELEGRAPH COMPANY.**—The Directors of this Company announce the payment on January 15th next of interest of 3s. per share, less income-tax, or at the rate of 6 per cent. per annum on the Preference shares of the Company for the quarter ending December 31st, and the usual interim dividend of 2s. 6d. per share on the ordinary shares, free of income-tax, in respect of profits, for the quarter ended September 30th last. The register of transfers will be closed from January 8th to 15th, both days inclusive.

**EASTERN AND SOUTH AFRICAN TELEGRAPH COMPANY.**—This Company notifies that the coupons due on January 1, 1891, on their Five per Cent. Mortgage Debentures will be paid on and after that date at the banking house of Messrs. Barclay, Bevan, and Co., 54, Lombard-street, E.C. Coupons should be left at the bank three clear days for examination.

**EASTERN EXTENSION TELEGRAPH COMPANY.**—The Directors of this Company have declared an interim dividend for the quarter ended September 30th of 2s. 6d. per share, payable on the 15th proximo.

**GREAT NORTHERN TELEGRAPH COMPANY.**—A half-yearly interim dividend at the rate of 5 per cent. per annum is announced by the Board of this Company, payable on the 1st prox.

**GREENWOOD & BATLEY.**—The Directors of Greenwood & Batley have declared an interim dividend at the rate of 7 per cent. per annum on the Preference shares; but have decided to postpone the consideration of a dividend on the ordinary shares until the end of the financial year.

**SIMONDS STEEL AND IRON FORGING COMPANY.**—On Tuesday this Company was, upon the petition of a shareholder, ordered by Mr. Justice Chitty to be wound up.

**UNITED RIVER PLATE TELEPHONE COMPANY.**—This Company notifies that the transfer books of the 5 per cent. debenture stock of the Company will be closed from the 17th to the 31st inst. (both days inclusive), for the purpose of preparing the half-yearly interest warrants.

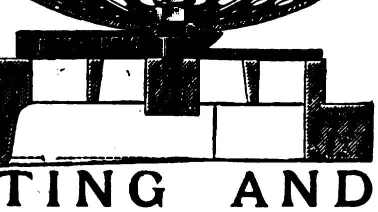
**WEST COAST OF AMERICA TELEGRAPH COMPANY.**—The coupons due December 31st on the Debentures of this Company will be paid by Messrs. Barclay and Co., Lombard-street. Coupons should be left three clear days for examination.

**WESTERN AND BRAZILIAN TELEGRAPH COMPANY.**—The traffic receipts of this Company for the week ending December 12, 1890, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £4,154.

**WHITE'S ASBESTOS (LIMITED) v. HOARE.**—This action came before Mr. Justice Day on Tuesday, and was adjourned until Friday. It is to recover £790, being the allotment money and first call of 5s. per share on 1,250 shares, and interest, the defendant bringing forward a counter-claim asking to have the contract to take shares rescinded on the ground that some of the statements in the prospectus were not true.

NEW VALVE

No Rubber, Percha, or Leather.



One-half the price of Rubber or Metal.

FOR CIRCULATING AND AIR PUMPS.

Unaffected by any Lubricating Oils. Does not Expand in diameter. Feed Water may be worked at any temperature Suitable for any shaped guards. Only one quality manufactured.

"12, John-street, Sunderland, 26th Sept. 1885.

"DEAR SIRS,—In reply to your letter of the 25th inst., the Valves I got from you have done their work well, and ARE AN UNQUALIFIED SUCCESS. I will continue to get them from you as required.—Yours faithfully, JAMES WESTOLL."

For further Testimony and Prices, apply to MOSSES & MITCHELL, 68-71, Chiswell Street, London.

# THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 658.—Vol. XXVI. FRIDAY, DECEMBER 26, 1890. Price Fourpence.

## NOTES.

If the duties of the committee which has been appointed by the Board of Trade be strictly "to consider whether any, or if so what, steps should be taken for the provision of electrical standards," it may be presumed that the work is of a purely scientific character. If so, the selection is an admirable one, and there are excellent reasons for excluding the commercial element. The legalisation of the ohm is a matter which can well be left to the distinguished representatives of the learned societies. But when the time comes to appoint a committee of reference in connection with the practical work which will soon have to be done, we hope that the representative principle of our national constitution will be observed, and that those for whom legislation is made, should have a hand in the making. We should like to have seen on the list the name of the man who in 1885 was the first to draw attention to "The Necessity for a National Standardising Laboratory for Electrical Instruments," and without whose services the recent movement which was initiated by the Electrical Trades Section of the London Chamber of Commerce would not have been put in so practical a shape.

The dispute between Mr. Chamberlain and the Chelsea Electricity Supply Company, which commenced in the House of Commons, has been continued in the columns of the *Times*, and the recent fogs have introduced a fresh element into the question. On Monday evening we visited the Chelsea station, with a view of ascertaining a few facts which may be of interest to our readers. In the first place, we understand that Mr. Chamberlain's house is near the middle of a block which is fed at each end from the station. The pressure at his terminals may therefore be somewhat lower than at the end of the feeder, but this will not account for any really appreciable fall. We understand that his voltmeter, of which we have heard so much, is of the Davies make, of which we know but little, and therefore can say nothing. There has been no regular and continuous automatic record of the volts at Chelsea, but a recording voltmeter has been used there of late, and very shortly similar instruments will be placed in each sub-station, and if Mr. Chamberlain does not cease from troubling it is probable that one will be fixed as near as possible to his terminals. His statement that his voltmeter has been carefully checked and passed as accurate by the officers of the Supply Company is not altogether exact. In the absence of a legal standard, voltage may be still said to be a matter of opinion; and, in the opinion of some, Mr. Chamberlain's voltmeter reads too low.

Passing now to the defect, which has been exaggerated into a breakdown, comparable almost with that of the London Electric Supply Corporation, the engineer of the Chelsea station has a very good case to make out, and one the facts of which all electrical engineers will be interested to learn. The distribution at Chelsea is effected, as most of our traders are aware, by the charging and discharging of batteries both at Draycott-place and at three sub-stations. From midnight until 4 p.m., when the ordinary load is light, half a battery—that is to say, one-half of the batteries at each sub-station—is being charged, all the sets being in series. The lighting during this period is carried on by means of the several "half-batteries." At about four o'clock in the afternoon, or at any other time occasioned by the demand, both halves are placed in parallel on the distributing circuit. Ever since the station has started this system has worked very well, and continued to do so until the fogs of the past few weeks.

We were prepared to hear that the Chelsea Company had yielded to the demands of consumers to such an extent that its generating and distributing plant had been overloaded in a manner similar to that of the London Electric Supply Corporation, and that a breakdown had ensued. We learn, however, that the sub-stations are not nearly loaded to their full capacity under ordinary circumstances, and in the spring of this year two continuous-current transformers and one additional dynamo had been ordered in view of the approaching winter, and it was the intention of the Company to run these motor transformers during periods of heavy load for the purpose of supplying current to the distributing circuits, and thus to relieve the batteries. But only one of these transformers has been delivered, and is at present under test at Draycott-place.

We have seen the output curve of the station during one of the recent foggy days, and found that at 7 in the morning instead of a fall, after a short early morning load, the output of the station was rising and continued to rise until 8 o'clock, after which there was a flat top until 2, then a sharp peak and a slight fall, after which the ordinary afternoon and evening load rose from 4 with a maximum from about 6:30 to 8 and then dropped into the usual way. The area as judged by eye was distinctly greater than *twice* that of an ordinary load curve so well known to our readers. This excessive output, due entirely to the fog, and not relieved, as had been intended, by the transformers, fell upon the batteries. It is obvious that there was no time during which they could be charged,

Digitized by Google

and hence it has been necessary on several occasions to cut off the consumers' circuits from 3 a.m. until 4 p.m., during which time charging took place.

THE so-called complete breakdown of the Chelsea Company therefore, resolves itself on investigation into a partial failure of supply under circumstances which, as Mr. IRVING COURTNEY states in his letter to *The Times*, puts the resources of even the old-established gas companies to a severe test. The inability, however, of the Chelsea Company to meet the sustained demand for current which results from that by no means uncommon occurrence, a London fog, is a somewhat curious commentary upon the many bold statements as to the great superiority of the "storage" system which were put forth at he time of the company's inception. A system of storage is undoubtedly a great desideratum, but secondary batteries as employed by the Chelsea Company are in reality not used as *storage* batteries, but merely as transformers; and apparently when there is any sudden strain, moving machinery, continuous current transformers, to wit, must as in other systems be relied on.

THE cleverly-written article which we reproduce in another column on the proposed railway under South Kensington will be appreciated more fully now than if it had appeared ten or twelve years. South Kensington science was then under a cloud. There was as much talk about and as poor teaching in science as there is at present in art. But it has lived through its period of sinecures and jobs, and the reputation which it has earned is solely due to the individual merits of such men as RÜCKER, BOYS, UNWIN, and AYRTON. These have completely thrown into the shade the old stock whose names are still to be found in "Whitaker's Almanac." It is probable that the promoters of the South Kensington and Paddington Subway Company overlooked the disaster with which they threatened the laboratories, or it is possible that they fail to appreciate their value. If a subway is to be made from north to south, we could suggest a more easterly route which would place Westminster engineers within reach of the Hampstead district.

IN a note presented recently to the Comptes Rendus Mr. BOULOUCH enters elaborately into the theory of the BUNSEN photometer, and shows that its accuracy depends on the truth of the assumption that the screen diffuses light equally in all directions. This is no doubt the case, not only with this photometer, but with RUMFORD'S; yet any error which may arise in this way must be quite negligible compared with the other errors of observation. If such screens were not equi-diffusive, they would appear to vary in brightness, according to the angle at which they are viewed. No difference of this kind is perceptible to the eye, and it is a needless refinement to consider such matters in detail, when large divergences in measurement are possible among different observers, and when it is not even possible for the same experimenter to reproduce his measurements with precision. It would be far more profitable to experiment with different varieties of BUNSEN screen, with the object of finding the conditions of greatest sensitiveness. The experiments of Mr. BOULOUCH only confirm these remarks, for, after finding how to eliminate any error due to the defective diffusion of the screen, observations are taken at different angles of incidence, and presumably with great care; yet the average error of observation is more than two per cent., and since it is well known that this is the limit of accuracy of a highly experienced observer, the source of error in question might well have been left unnoticed.

IT is well known that a thermo-electric junction forms, in conjunction with a delicate low-resistance galvanometer, an excellent form of thermometer. Its capacity for heat is very small, and it occupies little space. For the measurement of high temperatures it is especially suited, and as a pyrometer it has been advantageously used in many researches. Those fortunate enough to have the *entrée* to the Royal Society *soirée* in May last will remember the beautiful experiment shown by Professor ROBERTS AUSTIN, in which a simple thermo-electric joint was used for exhibiting the recalescence phenomena occurring in cooling iron and steel. One valuable property of such a thermometer is, however, not sufficiently recognised, viz., the great range of sensibilities which may be obtained by altering the resistance of the circuit. It is characteristic of electrical quantities generally, that while their magnitudes may vary between very wide limits, their values can always be determined with great accuracy; thus, with Sir WILLIAM THOMSON'S series of instruments, it is possible to measure with the same degree of precision currents varying enormously in magnitude; and a low resistance strip shunted with a sensitive high resistance galvanometer forms an ammeter whose range can be varied between very wide limits by the insertion of resistance into the shunted circuit. Many of these advantages are possessed by the electric thermometer, and it is only necessary to determine with precision the thermo-electric constants of the metals employed to render the instrument accurate as well as adaptable.

THIS task appears to have been undertaken by Messrs. CHASSAGNY and H. ABRAHAM, who have described their researches in three Papers presented to recent numbers of the *Comptes Rendus*. They have shown that the thermo-electromotive forces generated at temperatures varying between 0 deg. C. and 100 deg. C. can be determined to one ten-thousandth part of their value; and also that a parabolic function of the temparature is not a sufficiently accurate representation of the volts generated by the thermal actions going on in the circuit, since an error exceeding 0·2 per cent. may arise from using such a formula. According to these investigators, the formula which gives, correct to $\frac{1}{50}$th of a degree, the thermo-electric volts generated in an iron copper circuit, when the junctions vary between the temperatures of 0 deg. C. and 100 deg. C., is $V(t + 273) = a\,t + b\,t^2 + c\,t^3$, where V is the number of volts generated, $t$ is the temperature difference of the junctions in degrees Centigrade, $a = 3{\cdot}566 \times 10^{-3}$, $b = 8{\cdot}383 \times 10^{-6}$, and $c = -3{\cdot}265 \times 10^{-8}$.

IT might be imagined that after delivering the course of Cantor Lectures on "Electro-magnets" Prof. S. P. THOMPSON

Digitized by Google

would have exhausted his subject, dealing, as he did, not only with the theory of the subject, and providing a number of very useful working formulæ, but also going most fully into the history of the matter. He has, however, recently delivered a presidential address to the Junior Engineers on "Electro-magnetic Mechanisms," which were briefly touched upon in the concluding Cantor Lecture. The subject is dealt with from an engineering point of view, and deals with the details and construction of a large number of mechanical devices for taking advantage of the pull of electro-magnets for a great variety of purposes. We commence the publication of this address in the present issue.

**Dover.**—In his report to the Town Council, Mr. J. A. Timmis recommends the adoption of the three-wire system and the erection of a 20,000-light plant.

**Scarborough.**—The Scarborough Local Authority have decided to make application for a provisional order and the repeal the Scarborough Electric Lighting Order, 1883.

**The Electrical Census Counter.**—The counting of the population at the taking of the next census in Austria will be effected by means of the electrical counter, as was done in the recent American census.

**Nimes.**—The Compagnie Nationale d'Electricité (Ferranti system) are pushing forward the electric light installation at Nimes, which will probably be ready in four or five months, for the supply of some 2,000 lamps. The capacity of the station will be 5,000 to 6,000 lamps.

**Reduction of Telephone Rentals.**—The South of England Telephone Company has issued notices in towns served by their lines to the effect that they have reduced their tariff to a uniform rate of £8. 8s. per annum, on a yearly agreement, for lines within one mile radius of their exchange.

**The Telephone in Japan.**—A telephone trunk line between Tokio and Yokohama will be opened in January. The line is 18 miles long, and the charge to subscribers will be $40 per annum at the capital, and $35 at Yokohama. Five minutes' conversation between two non-subscribers will cost about 7d.

**A Government Report on Rubber.**—The United States Government has forwarded instructions to its Consuls throughout the world to prepare special reports relative to the India-rubber interest, whether it relates to the commerce in crude rubber or to the manufacture and sale of the finished product.

**The Electrical Transmission of Power.**—We have it on the authority of *l'Eletricité* that a leading French Company proposes to effect the electrical transmission of 10,000 horse-power to a distance of 120 miles at a pressure of 12,500 volts. The sea is being used as a return. The site of this proposed installation is stated to be in Spain.

**Mutual Telephone Company.**—Mr. George J. Somerville, who has been manager of the Aberdeen district of the National Telephone Company during the past six years, has been appointed by the Mutual Telephone Company as their district manager for Lancashire. At Manchester the erection of wires and the fitting up of the Exchange of the Mutual Company will be at once proceeded with.

**National Telephone Company.** — At the ninth annual *conversazione* of the National Telephone Company's staff and *employés*, which was recently held in Glasgow, some interesting statistics were given. It was stated that the average number of conversations carried over the company's wires in what may be called the Glasgow district, had risen during the past year to about 251,000 per week, or 13,052,000 per annum.

**Electric Traction in the United States.**—The 12 leading cities of the United States, from the point of view of electric traction, are Boston, with its 312 electric motor cars; St. Louis, 207; Rochester, 200; Pittsburg, 170; Cleveland, 162; Minneapolis, 110; St. Paul, 88; Cincinnati, 77; Nashville, 61; Davenport, 60; Milwaukee, 55; Richmond, 45. The systems represented are Sprague, Thomson-Houston, Short and Westinghouse. The Thomson-Houston Company has 130 lines, Sprague 108 lines, and Short 10 lines.

**A Long-lived Lamp.**—Mr. J. Lavender, jun., writes us as follows:—"*Re* long-lived lamp mentioned in your correspondence column of August 29th last. This lamp was removed from its holder on Thursday last, having done duty for 11,561¾ hours. The filament is unbroken. As stated in previous letter, it is an Edison-Swan lamp, 100 volt, 16 candle-power type. Total power in watts consumed prior to removal was 16·6. No photometrical measurement was taken. We have another lamp of same type, with record of 11,361 hours to Thursday last."

**Magnet for Blast Furnace Use.**—Messrs. Hughes and Gawthrop, of Pittsburg, employ a large electro-magnet for lifting pig iron from the pig bed in the cast house. It was manufactured by the Thomson-Houston Motor Company, and is capable of lifting a load of 3½ tons. In shape it somewhat resembles a bell with nearly vertical sides, standing about 20in. in height, and measuring about 24in. across the bottom. The magnet, which is attached to a crane, can be raised and lowered, and the load is dropped by simply shutting off the current.

**Croydon.**—The County Council has received from Mr. Preece a detailed report as to the electric lighting requirements of the town, and the probable cost of laying down the necessary mains. He estimates that a total length of 100 miles of mains will be necessary, of which 60 miles can be underground, and 40 miles overhead, the latter being for public lighting only. The underground mains will cost about £700 per mile, the overhead about £230 per mile. Under these circumstances the Corporation have decided, in their application to the Board of Trade, to mention £150,000 as the amount of capital which may be employed.

**Electricity on the Farm.**—M. Comille Gonzy, the proprietor of numerous small farms in the commune of Millas (Western Pyrenees), having an area altogether of nearly 1,500 acres, has, for some time past, been utilising a neighbouring stream for electric lighting purposes. He has now applied electric power to the working of a wine-crushing plant. Besides providing the power for lifting and driving purposes, electricity is made to work the pumps for irrigating the vines. The 180 16 candle-power lamps employed are distributed over all the farms, and the area which they cover may be judged from the fact that the length of telephone wire connecting the buildings is 62 miles.

**Guttapercha.**—The supply of guttapercha shows ominous signs of diminution, and the price has risen considerably. We give below the quantity imported and its value during the last four years:—

| Year. | Cwt. | £ | Per cwt. |
|---|---|---|---|
| 1887 ................ | 24,145 | 156,563 | £6·5 |
| 1888 ................ | 22,483 | 181,660 | 8 |
| 1889 ................ | 48,042 | 576,896 | 12 |
| 1890 (10 months)... | 60,494 | 686,013 | 11·3 |

**The Electrical Treatment of Wine.**—For the past twelve months a small 8 horse-power experimental plant, due to M. de Meritens, has been in operation at the Bercy works of MM. Pollet, where M. de Meriten's method of treating wine by electricity has been exhaustively tested and pronounced satisfactory by competent authorities. The dynamo employed is a 25 volt alternator, having a frequency of 116. The wine to be treated by electricity with a view of increasing its "keeping" qualities is passed through a small tube containing a series of silver discs connected to the poles of the alternator. The wine as it flows through the tube is thus traversed by a rapidly alternating current, which it is supposed destroys the ferments. The experimental plant is capable of treating 22 gallons of wine per hour. The process has been tried on wines of all kinds, and the results have been most marked with the light Algerian wines, whose bad "keeping" qualities have hitherto prevented their exportation.

**Spliced Carbons.**—According to *Modern Light and Heat* the Concord (N.H.) Gas and Electric Light Company is making

Digitized by Google

use of an ingenious appliance by which they use up all the short pieces of arc lamp carbons. When the trimmers bring in the pieces of carbon from the lamps they are assorted and laid end to end, to make about 8in. in length. They are then placed in a machine which makes a dowel on one piece and a socket in the other, after which they are joined together with a conducting, heat-proof cement of low resistance. This company has been using these spliced carbons as negatives for a year and more, and have fully proved their success. The saving in carbons is said to exceed 30 per cent.

**Proposed Electric Railway between Vienna and Budapest.**—It is announced, says the Vienna correspondent of *The Times*, that a company is about to be started, with a capital of 38,000,000fl. (£3,800,000), for constructing an electrical railway between Vienna and Budapest. The distance of 250 kilometres (156 miles) is to be accomplished in two hours and a-half by trains comprising only first-class carriages. The price of the return ticket is to be 9fl. 80kr., about 18s. As it now takes four hours and a-half to travel between the Austrian and the Hungarian capitals in an express train, the saving of time promised by the new company is a boon that will seem to many more tantalising than attainable.

**The Metropolitan Electric Supply Company and the Fogs.**—On making inquiries from the Metropolitan Electric Supply Company, we learn that as the fogs have not come upon them suddenly, the demand has been fairly easy to meet, though, of course, it has entailed considerable extra care on the part of the staff. The load from all the stations has been remarkably uniform, from 9 a.m. to 4 p.m. the average increase being about 15 per cent. more than the normal load. Of course, after 4 p.m. the ratio between the lamp supply and lamp connection has remained the same, being much about the same figures as were given at the Society of Arts, with the exception of Rathbone-place station, which is now assisting the London Company by lighting the Lyric Club, Prince of Wales Theatre, &c.

**Meserole Dry Battery.**—The mixture for filling dry cells prepared by Mr. A. V. Meserole consists of the following solid ingredients in the form of powder: Charcoal, 3 parts; mineral carbon or graphite, 1 part; peroxide of manganese, 3 parts; lime hydrate, 1 part; white arsenic (oxide), 1 part; and a mixture of glucose and dextrine or starch, 1 part; all by weight. These are intimately mixed dry and then worked into a paste of proper consistency with a fluid solution composed of equal parts of a saturated solution of chloride of ammonium and chloride of sodium in water, to which is added one-tenth volume of a solution of bichloride mercury and an equal volume of hydrochloric acid. The fluid is added gradually and the mass well worked up.

**Telegraphic Statistics.**—The following comparative figures may be of interest:—

| Country. | Miles of Telegraph Wire. | Messages per Annum. | Messages per Annum per Mile of Wire erected. |
|---|---|---|---|
| United States | 776,500 | 56,000,000 | 72 |
| France | 220,890 | 30,050,000 | 136 |
| England | 180,000 | 50,000,000 | 277 |
| Russia | 170,500 | 10,280,780 | 60 |
| Australia | 105,300 | 12,000,000 | 114 |
| Canada | 58,500 | 4,027,581 | 69 |
| Italy | 19,500 | 7,000,000 | 360 |
| Japan | 16,500 | 5,000,000 | 303 |
| New Zealand | 11,375 | 1,835,394 | 161 |

**A Proposed Electric Tramcar Gearing.**—According to the *Electrical Engineer* of New York, Mr. E. S. Pillsbury proposes to overcome the difficulties connected with tramcar starting by using a turbine as an intermediate gearing, or rather a combination of pump and turbine, constituting a liquid gearing. In effect the armature is coupled to a rotary pump, and the car wheel axle to a turbine; these two are enclosed together in a small iron vessel with water. The armature starts at full speed driving the pump, and the turbine takes up the speed evenly and gradually, the two being locked when the speed becomes equal. As, for high-speed turbines, a 15in. wheel of modern build will give 350 horse-power at 600 revolutions, it is easy to see that the size of the arrangement need not be great. The idea is very similar to the one which we suggested in an editorial note on the first page of the present volume, and if it were further improved by making the delivery of the pump it variable, would be identical.

**Electric Installation at Partenkirchen and Garmisch.**—According to the *Loisach Messenger*, May 1, 1891, has been fixed as the date for starting this installation. The plant will be supplied by the Esslingen Maschinenfabrik. Power is to be derived from the Loisach Falls, where generally there are at least 10 cubic metres of water per second available. Steam engines will, however, be put down as a reserve. The electrical plant will consist of two 60 horse-power dynamos coupled in parallel, and separately excited by two small machines. The current will be supplied at 1,500 volts pressure, and will, at the distributing stations in the two towns, drive motors, which will in turn drive 120 volt dynamos. The latter will supply the lights through a network of mains on the 3-wire system.

**Royal Naval Exhibition.**—The Electric Lighting Committee, the members of which are Sir William Thomson, Captain Eardley Wilmot, R.N., Mr. E. H. Carbutt, Mr. W. H. Preece, and Mr. J. I. Thorneycroft, have decided to entrust the lighting of the entire Exhibition to Messrs. Siemens Bros. and Co. The engines will be supplied by Messrs. Willans and Robinson; and the boilers for the electric light, as well as for the machinery in motion, will be from the well-known works of Messrs. Davey, Paxman, and Co. Some 200 arc lamps and 2,000 glow lamps will probably be required to illuminate the buildings and grounds, and the dynamos will also have to supply current for several interesting applications of the transmission of power and for the lighthouse of Messrs. Chance Bros., which will form one of the features of the Exhibition.

**Electrical Standards and the Board of Trade.**—The President of the Board of Trade has appointed a committee, consisting of the following gentlemen, to consider whether any, and if so, what steps should be taken for the provision of electrical standards:—Lord Rayleigh, F.R.S., Sir William Thomson, F.R.S., representing the Royal Society; Prof. G. Carey-Foster, F.R.S., R. T. Glazebrook, Esq., F.R.S., representing the British Association for the advancement of science; Dr. John Hopkinson, F.R.S., Prof. W. E. Ayrton, F.R.S., representing the Institution of Electrical Engineers; E. Graves, Esq., W. H. Preece, Esq., F.R.S., representing the General Post-Office; Courtenay Boyle, Esq., C.B., Major P. Cardew, R.E., representing the Board of Trade. The first meeting of the committee will be held at the Board of Trade on Thursday, January 15th. Sir Thomas Blomefield, of the Board of Trade, will act as secretary to the committee.

**The Carpenter-Nevens Electric Car Heater.**—This form of electric heater, which is being introduced in the United States, consists of three crimped wires of high resistance attached to a backing of asbestos. The asbestos is enclosed in sheet-iron strips about 3 inches in width and about ¼ inch in thickness. The heating apparatus extends from one end of the car to the other under the seats. It is enclosed on all sides except the face in a copper reflector, in order that the heat may be radiated in the proper direction. The circuits are arranged so that one, two, or three of the wires can be switched on in accordance with the demand for heat. The switches are located on the platform, and are in charge of the motor man. When current is turned into the cold resistances they will take at first 8½ or 9 amperes at 500 volts pressure (6 H.P.), but for a few minutes only. As the wires begin to heat the current decreases until it reaches about 1½ amperes (I.H.P.) The consumption of current will then remain constant at this point.

**The Chelsea Electricity Supply Company.**—At the meeting of the Chelsea Vestry on Tuesday last week a letter was read from the Chelsea Electricity Supply Company giving notice of their intention to discontinue the supply of electricity between the hours of midnight and four o'clock in the afternoon, and stating that this was only a temporary measure made necessary by the continuance for several days of heavy fogs.

Digitized by Google

Mr. H. J. Wright complained, as a consumer, of this proposal. He stated that the Company had already cut off the supply, and on Saturday morning he was without any light at all. He moved, "That as the Company are applying for a further extension of their area of supply, the Board of Trade should be asked to refuse their consent to such application, unless they can compel the Company to give a continuous supply night and day even during the foggy weather." Mr. Wall, in supporting the motion, said the Vestry should have kept the electric lighting of the parish in its own hand, and never allowed it to be taken up by such small companies. The motion was carried.

**Electricity in the U.S. Navy.**—Commodore G. Dewey, Chief of the Bureau of Equipment, in his annual report to the Secretary of the U.S. Navy, says:—"The lighting of ships of war by electricity, which was inaugurated by this Government, has now become so essential that no war ship is considered complete which is not so lighted. During the year substantial progress has been made in the development and advancement of the system, which is being employed in the new ships, and progress abroad has been critically noted. Electric lighting plants have been installed on board seven vessels, and the work of installation is actively progressing upon four others. Special attention has been given during the year to the subject of means of interior communication on shipboard, and a telephone system is soon to be added experimentally to other devices in use on board one of the new cruisers. Night signalling by electricity has also been, and is still, actively under consideration, and it is believed that a system will have been devised in the near future which will meet the increasing necessity of the service in this respect. The great importance of an adequate method of communication at night between ships of a squadron or fleet makes necessary the utmost care in the consideration of the subject."

**Sir William Thomson.**—A private meeting, convened by the Lord Provost, Principal Caird, Sheriff Berry, Sir James King, Bart., Sir John Neilson Cuthbertson, the Lord Dean of Guild, and Mr. William M'Ewen, was held in the Glasgow Municipal Buildings last week. It was unanimously resolved that Sir William Thomson should be asked to sit to some eminent artist for a portrait, to be placed in the University.—At the ordinary meeting of the Philosophical Society of Glasgow last week the following resolution was put from the chair and unanimously agreed to:—"That the Philosophical Society of Glasgow desires to convey to Sir William Thomson its congratulations on his election to the presidentship of the Royal Society. The members of the Society cannot forget the warm interest that Sir William has always shown in the Philosophical Society, and they feel proud that one who has been a member since 1846, and who has been twice its president, has been called upon to occupy the chair of the leading scientific society in the world. They feel sure that the accession to this office by Sir William Thomson will be hailed with acclamation by all scientific men as a just tribute, not only to his eminence as a mathematician, physicist, and electrician, but also to his many estimable qualities as a man."

**Swansea.**—At a meeting of the Electric Lighting Committee of the Swansea Corporation, which consists of the whole of the corporation, held on Tuesday last week, it was decided to accept the tender of Messrs. Crompton to erect 23 arc lights of 2,000 candle-power at a cost of £25 each per annum. Several reports on the subject of electric lighting were read, and, amongst others, one from Mr. W. H. Preece, who stated that the amount of popular support which the corporation would secure for their action in introducing the electric light into the borough depended entirely upon the success with which the principal streets were illuminated. The public, he said, expected a blaze of light, and they were invariably disappointed when the street illumination was not materially improved. Arc lamps, when placed not too far apart, and when they burnt with steadiness, invariably secured approbation. Glow lamps, unless of considerable power, rarely did so. The mere substitution of an incandescent fibre for a gas flame of similar light-giving power was generally a great disappointment. The success of the light either by arc or by glow lamps depended essentially on the way in which the light was distributed. After very careful consideration 120 feet had been taken as the standard distance at which 500 watt arc lamps should be placed apart in the main thoroughfares of the City of London. In Swansea they should not be further apart than 200ft. in the principal streets. The corporation must expect to pay more for the electric light than they had hitherto paid for gas, but they also must expect a very much better light.

**Complimentary Dinner to Prof. Ewing.**—On Saturday evening last Prof. Ewing, who has filled the chair of Engineering and Drawing in University College since its opening seven years ago, was entertained to dinner in the Queen's Hotel previous to his departure to occupy the chair of Mechanism and Applied Mechanics in Cambridge University. Lord Provost Mathewson presided, and there was an attendance of between 60 and 70 gentlemen. Mr. G. W. Baxter proposed the toast of the evening, and in doing so gave a brief sketch of the life of Prof. Ewing, stating that he had a most distinguished career as a student at the University of Edinburgh, and that the Japanese Government unsolicited extended the term of his tenure of office of the chair of Mechanical Engineering in the University of Tokio from three to five years. During the seven years that Prof. Ewing had been in University College he had done much excellent work both in civil and mechanical engineering, and as an electrical engineer he had made himself a name which would not easily be forgotten. Prof. Ewing, in reply, said he ventured to claim on behalf of his colleagues as well as of himself that they had endeavoured to aim high in University College, and if they had not succeeded in getting crowded benches they had at least succeeded in this, that the work which had proceeded from many of the laboratories had received the warmest possible welcome in the highest places, and that their little College, after only six years of existence, had had the official stamp placed upon it, which admitted it to the membership of the family of the Uuniversities of the country.

**Tariff Changes Made by the McKinley Bill.**—The changes in the tariff made by the McKinley Bill will affect material used in electrical interests as follows, says the *Electrical Engineer* of New York:—Aluminium, formerly free, increased to 15 per cent. *ad valorem.* Copper ores, reduced from 2½ cents to 1½ cents. Old copper for re-manufacture, reduced from 3 cents to 1 cent. a pound. Copper in plates, bars, or ingots not manufactured, reduced from 4 cents to 1¼ cents. Copper in rolled plates, rods, pipes, sheathing, remains at 35 per cent. *ad valorem.* Tin remains at 4 cents a pound. Zinc in blocks or pigs is increased from 1½ cents to 1¾ cents a pound. Old zinc, for re-manufacture, increased from 1¼ to 1¾. Chromic acid, 6 cents per pound instead of 15 per cent. *ad valorem.* Bichromate of potash remains the same at 3 cents per pound. Nickel, &c., per pound, 10 cents, reduced from 15 cents. Electrotype plates remain at 25 per cent. *ad valorem.* Thin blown glass is increased to 60 per cent. *ad valorem* from 45 per cent. Mica is raised from the free list to 35 per cent. *ad valorem.* Blue vitriol, or sulphate of copper, reduced from 3 cents to 2 cents. Sal-ammoniac changed from 10 per cent. *ad valorem* to ¾ cents specific. Sal-soda and soda ash remain at ¼ cent. Caustic soda has been reduced from 1½ cents to 1 cent. Sulphuric acid is increased from free to ¼ cent a pound. Wire and wire rods are reduced ¼ cent a pound where they are not covered. Where they are covered with cotton, silk, or the like, they are increased 1 cent a pound. Flat steel wire is increased from 45 to 50 per cent. *ad valorem.* The schedule shows that of the articles mentioned the tariff on 44 per cent. has been reduced materially, while it has been increased on 28 per cent., and unchanged on 28 per cent. Parts made of porcelain, such as switch bases, socket details, &c., promise to be dearer, and the manufacturers in this country are likely to have a large amount of business thrown into their hands. It is claimed that the German article will practically be excluded from the market. It is also claimed that a stimulus will be given by the tariff to the manufacture of fine instruments. The general belief, even among the many opposed to a higher tariff, is that the springing up of many new factories and shops requiring electric light and power will have a good effect on electrical industries.

## MAGNETISM IN IRON AND OTHER METALS.*

### XXXVIII.

BY PROF. J. A. EWING, F.R.S.

(*Continued from page 165.*)

§ 136. **Effects of Torsion on Magnetic Quality.**—The influences of twisting strain on the magnetic quality of metals has engaged the attention of many experimentalists, beginning with Matteucci,† who, in 1847, examined ballistically the change of magnetism undergone by an iron rod when it was twisted back and forth, while a magnetising current was kept up in a surrounding solenoid. Wertheim, E. Becquerel, and Wiedemann followed on the same lines,‡ and the subject was taken up by Sir William Thomson in one of the sections of his investigations of the electro-dynamic qualities of metals‖. More recently a number of other workers have pursued the matter in great detail. The results of their investigations are much too complicated to admit of anything like full statement here; we must be content with an account of some of the more conspicuous facts.

The general result of early experiments was to show that when a rod of soft iron, exposed to longitudinal magnetising force, was twisted, its magnetism was reduced, by torsion, in either direction. In this effect, as in all effects of stress, we have to distinguish between the irreversible initial effect of the first application (due to molecular instability) and the effect which becomes manifest when a cycle of strain is repeated. The initial effect of torsion will depend on the past history of the piece, but the cyclic effect is, in soft iron, of this character, that twisting, to either side, reduces the induced magnetism, and untwisting increases it. But this effect is very small for small angles of twist. Moreover, as with other effects of stress, the changes of magnetism exhibit hysteresis. This was pointed out by Sir William Thomson, who has given curves showing the manner in which the magnetism induced in an iron wire by a constant magnetic field changes as one end of the iron wire is twisted to and fro while the other end is held fixed. The typical form into which the curves settle after repeated twistings is shown in Fig 114, which is copied from his Paper. From the form of these curves it is clear that if the effects of hysteresis were eliminated—as they no doubt might be, at least in part, by vibrating the wire—we should have a single curve resembling a parabola with its vertex at the top of the diagram. Thus in the absence of hysteresis we should find the influence of torsion in reducing the induced magnetism to be indefinitely small for small angles of twist, and to increase initially in proportion to the square of the twist.

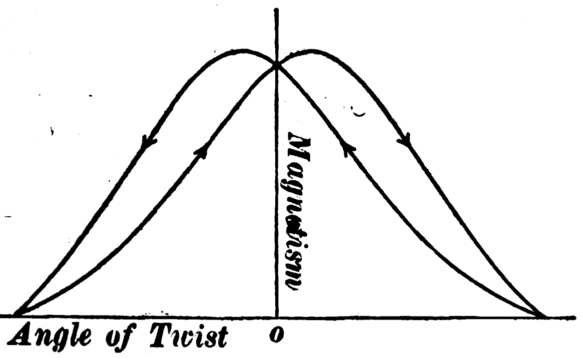

Fig. 114.—Effect of Twist on the Magnetism of Iron.

§ 137. **Effects of Torsion Due to Magnetic Aeolotropy.**—Sir William Thomson has, in fact, pointed out that these results are to be anticipated from what is known regarding the effects of simple torsion and simple compression on the magnetic susceptibility of iron.* Experiments in which the metal is subjected to longitudinal pull or push and to transverse pull, have shown that a simple pulling stress or a simple pushing stress develops an æolotropic quality in respect of magnetic susceptibility, producing (in iron) greater susceptibility along than across the lines of pull, or less susceptibility along than across the lines of push, provided the magnetisation is not so strong as to pass the Villari critical value. Now in torsional strain, each portion of the twisted rod experiences a simple shearing stress, which may be regarded as made up of a pulling stress in a direction inclined at 45deg. to the direction of the length, and an equal pushing stress also inclined at 45deg. and at right angles to the pulling stress. Thus, if *a b c d* (Fig. 115) is a particle anywhere in the front half of the rod, which is twisted in the manner shown by the arrows, the twisting produces a shearing stress in *a b c d* that is equivalent to a pull on the faces *a b* and *c d*, combined with an equal push on the faces *d a* and *b c*. The effect is to increase the magnetic susceptibility along the direction *p p* and to reduce it along *p′ p′*. For small stresses these effects are no doubt equal. Hence in the direction of the length of the rod, which is equally inclined to *p p* and *p p′*, there is, virtually, no change of susceptibility.

The effect of torsion is to give a helical quality to the magnetisation, producing a circular component which is superposed upon the original longitudinal magnetisation. The lines of magnetisation are no longer coincident in direction with the lines of magnetic force; they become in the case considered above right-handed screws. The effect of this on the magnitude of the longitudinal component is at first indefinitely small, but as the angle of torsion increases the growth of the circular component begins to detract from the longitudinal magnetism, for magnetisation in one direction is prejudicial to magnetisation in other directions, as the molecular theory and the phenomenon of saturation suggest.

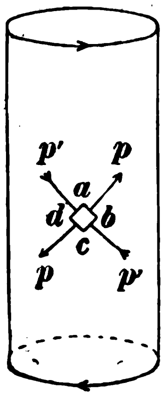

Fig. 115

This consideration of the magnetic æolotropy produced by the pull and push into which torsional stress may be resolved supplies a key to many of the observed facts about magnetism and torsion. At the same time it fails to explain many of the facts. The influence of æolotropy is, no doubt, always present in the phenomena of torsion, but other considerations of a less obvious kind also enter, and these become in some instances so influential that the effects of æolotropy are entirely masked. This is notably the case with nickel. With soft iron, on the other hand, most of the observed effects of torsion admit of fairly complete explanation in the lines suggested by Sir William Thomson, especially when allowance is made for the complications to be anticipated from hysteresis.

§ 138. **Production of Longitudinal Magnetism by Twisting a Circularly Magnetised Wire.**—From the foregoing account of how a circular component of magnetisation is developed by torsion in a longitudinally magnetised wire or rod, it will be evident that the converse action should occur, namely, that twisting a circularly magnetised rod should make it develop

Digitized by Google

longitudinal magnetism. This fact was observed in 1858 by Wiedemann, who found that an iron wire conducting an electric current, and therefore circularly magnetised, becomes a magnet when twisted.* Following Thomson, we may explain this observation as a consequence of æolotropy by resolving the magnetising force, whose direction is O A (Fig. 116), into components along the lines of pull, O $p$, and push, O $p'$. Taking the case of iron, below the Villari critical point, and twisted in the manner shown in the diagram, the susceptibility is greater along the lines of pull, O $p$, than along the lines of push, O $p'$. Hence the resultant magnetisation will be less inclined to O $p$ than to O $p'$; in other words, it will take some direction, O R, which gives a longitudinal component of magnetisation directed towards the bottom of the rod. This is, in fact, the kind of longitudinal magnetism which is found.

It might, however, be supposed, in view of the Villari reversal, that under sufficiently strong circular magnetisation the longitudinal component developed by twisting would become reversed. Experiment shows that this does not happen even when a very strong current traverses the wire. The explanation appears to lie in the fact that the stresses of pull or push due to torsion act not on the whole intensity of circular magnetisation but on components inclined at 45deg. Hence, though the circular magnetising force be strong enough to bring about saturation, the components of magnetisation on which the pull and push act remain below the Villari critical value, so that the effect of pull is still to augment and of push to diminish the components on which the pull and push act.†

These effects of torsion are found in dealing with residual magnetism as well as with induced. In Wiedemann's experi-

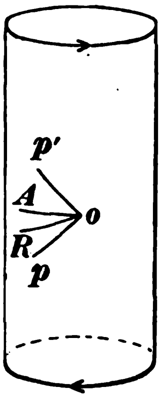

FIG. 116.

ment the same result (namely, the production of longitudinal magnetism by torsion) is noticed though the wire be not twisted until the current has ceased to pass. There is then a strong residual circular magnetism which is affected by torsion, just as might be anticipated from the fact that the residual magnetism of a bar magnetised in the usual way is affected like the induced magnetism by pull and push.

§ 139. **Torsional Strain Produced by Combining Circular with Longitudinal Magnetisation.**—A similar explanation applies to another discovery of Wiedemann's, namely, that if an iron wire or rod be both circularly and longitudinally magnetised, it becomes twisted, though no external mechanical force be used. The superposition of the two magnetisms turns the lines of magnetisation into screws, and the consequent expansion along the lines of the screws and contraction across these lines causes the rod to twist. In iron the effect of magnetising (unless the magnetising force be very strong) is to lengthen the metal in the direction of magnetisation. The direction which the twist is observed to take agrees with this.

In nickel, on the other hand, the effect of magnetising is to shorten the metal in the direction of the line of force. The twist taken by a nickel wire, subjected to superposed longitudinal and circular magnetising forces, is accordingly opposite to that of iron, as Prof. Knott has shown* by making a current traverse a nickel wire, which was at the same time exposed to the action of a magnetising solenoid.

(*To be continued.*)

* *Elektricität*, Vol. III., p. 680.

† This absence of reversal is referred to by Sir William Thomson as a difficulty; but the difficulty disappears when it is recognised that the Villari reversal depends rather on the value I in the direction of pull and push than on the value of H. Though the components of H along directions inclined at 45deg. to the axis may be indefinitely increased, the components of I along these lines remain too small to allow pull to produce reduction of magnetism.

## CAPACITY AND SELF-INDUCTION IN ALTERNATE CURRENT WORKING.—II.

BY GISBERT KAPP.

(*Concluded from page 199.*)

The analytical treatment of the various problems involved is rather complicated, and has the further disadvantage that the solution is generally obtained in the form of a more or less complex equation which does not directly appeal to our senses, but requires first some sort of translation from the mathematical into the common sense or practical form before we can make use of it. In this respect and also on account of its greater simplicity throughout, the graphic method of investigation is far preferable, and will in this article be exclusively employed. The general principle on which this method is based is so well known that only a few words of explanation are necessary. Imagine yourself looking at the crank of an engine, the line of vision being at right angles to the engine shaft. The crank pin will then appear to oscillate to both sides of the centre, and the distance at which you see the pin from the centre at any time will be a sine function of the time. Now substitute for the crank a line the length of which shall represent the maximum current, and let it revolve round one of its extremities with a speed corresponding to the frequency —for a frequency of 80 the line would have to make 80 revolutions per seconds—then the projection of this line on a vertical line would give the current flowing at any instant. Electromotive forces can also be represented in the same manner, but some care is required to plot the lines in the right direction so as to represent correctly not only the magnitude but also the sign of the quantities. We shall assume in all cases that the movement is clockwise. The top half of the diagram shall be positive and the bottom half negative. Now let us consider the current in a coil having self-induction at the moment when this current is a maximum—that is to say, when the line representing it is vertical. As soon as the current begins to diminish, that is as soon as the current line goes to the right of the vertical, the self-induction of the coil comes into play, tending to maintain the current at its maximum value. The E.M.F. of self-induction is, therefore, at this moment positive; that is to say, the projection of the line representing the maximum E.M.F. of self-induction in the coil must be in the upper or positive half of the diagram. This means that the E.M.F. of self-induction must be represented by a line at right angles to the current and to the left of it. Since this E.M.F. must be overcome by the E.M.F. of the machine, it follows that the latter (or at least that component of it which is necessary to counteract self-induction) must be at right angles to the current and to the right of it; or, as we may also express it, the E.M.F. must be in advance over the current by 90deg. That component of the E.M.F. of the machine necessary to overcome resistance must, of course, coincide with the current.

Now take the case of a condenser. When the E.M.F. between its plates has reached its maximum positive value the current is zero, and a moment after the condenser begins to discharge producing a positive current. If we represent the E.M.F. of the condenser by a vertical line in the top half of the diagram, we must therefore represent the current by a horizontal line to the left of the centre. The E.M.F. of the machine (or at least that component of it corresponding to the condenser) must of course be equal and opposite to the condenser E.M.F., and thus

* *Trans.* Roy. Soc. Edin., Vol. XXXII. (1883), p. 193.

Digitized by Google

we find that when a condenser is in circuit the machine E.M.F. lags a quarter period behind the current. We have, therefore, the following simple rules for determining the direction in which we must plot current and machine E.M.F.

I.—*Starting from the Current.*

(*a*). The E.M.F. required to overcome resistance coincides with the current.

(*b*). The E.M.F. necessary to overcome self-induction is a quarter period in advance of the current.

(*c*). The E.M.F. necessary to oppose the condenser E.M.F. lags by a quarter period behind the current.

II.—*Starting from the E.M.F.*

(*a*). Resistance-current coincides with E.M.F.

(*b*). Self-induction current lags by a quarter period behind E.M.F.

(*c*). Condenser-current is a quarter period in advance of E.M.F.

Bearing in mind these rules, it is always easy to build up the diagrams representing E.M.F. and current for any combination of resistance, self-induction, and capacity. Figs. 1 to 12 show how this is done for a few simple combinations. All the diagrams are drawn to scale, and the corresponding quantities are given in each case. In selecting these quantities the object was not so much to represent cases actually occurring in practice, but rather to make that selection which will render the diagram most instructive. In all cases the frequency has been assumed at 80 cycles per second, or $\omega = 500$.

I.—*Resistance and Self-Induction.*

Two cases are represented—the one with the self-induction coil L, in series with the resistance R (Fig. 1), and the other where the coil L forms a shunt to the mains leading from the alternator A to the resistance R (Fig. 3). In the latter case a resistance is assumed to be in series with the coil or forming part of it. The resistance R may be a useful resistance, such as a bank of glow lamps, but in it must, of course, be included the resistance of the mains. Fig. 2 is the diagram belonging to the series, and Fig. 4 that belonging to the parallel arrangement. In Fig. 4 $r$ is assumed to be zero, whilst in Fig. 4A it is assumed to represent a resistance of 33·4 ohms. In all diagrams the currents and electromotive forces are distinguished by indices referring to the corresponding part of the circuit. Thus, $I_R$ and $E_R$ denote current and E.M.F. in the resistance R, so that $I_R \times E_R$ represents the work done in the resistance. $I_A$, $I_C$, and $I_s$ denote respectively current through machine (alternator) into and out of a condenser and through the coil having self-induction. In the same way $E_A$, $E_C$, and $E_s$ represent respectively the E.M.F. generated in the armature of the alternator, the E.M.F. between the plates of a condenser, and the E.M.F. of self-induction. The indices are omitted where quantities coincide. For instance in Fig. 1, the current can only have one value, $I = I_A = I_s = I_R$, and hence the index is omitted in Fig. 2. Similarly the E.M.F. in the arrangement Fig. 3 can have only one value and the index of E is omitted in Fig. 4. The case represented in Fig. 1 is so simple as to require hardly any explanation. The E.M.F. of self-induction is $E_s = 5{,}000$ volts and necessitates the raising of the E.M.F. induced in the machine from 10,000 to 11,200 volts. In the case represented in Fig. 3 the machine E.M.F. need, of course, not be raised, but more current will flow through the armature. A self-induction coil of ·166 quadrants and no resistance will, under an E.M.F. of 10,000 volts allow 120 amperes to pass. This, combined with the 100 amperes flowing through R gives an armature current of 156 amperes. It is interesting to note how this result is affected by putting a resistance $r$ in series with the coil L. At first sight it might appear that now there should be less current passing through the machine. This is, however, not the case, as may be seen on inspection of Fig. $4_A$. Let $r = 33·4$, and assume for the moment that the current passing through the induction coil has remained unaltered. This gives us the point $I_s^1 = 120$ and $E_r^1 = 4{,}000$, being the product of $120 \times 33·4$, or the E.M.F. lost in the resistance $r$. To maintain this condition of things, the machine E.M.F. would have to be $E_A^1$, that is greater than 10,000 volts. The lamp current would be $I_R^1 > 100$, and the armature current would be $I_A^1$. Since, however, the machine E.M.F. is to be 10,000 volts, and not more, we must reduce the size of the whole diagram in the ratio of the lengths $0E_A^1 : 0E$. At the same time it will be convenient to rotate all the lines through an angle equal to that enclosed between these two lines in order to bring the lamp current back into the vertical position. This is a very simple geometrical operation, which need not be described at length, though it is shown in the diagram. The result is $I_r = 174$ amperes, $I_s = 110$ amperes, and $E_r = 3{,}700$ volts. Comparing these figures with those obtained from diagram Fig. 4, where $r = 0$, we find that although the addition of a resistance to the coil L (briefly called a choking coil) diminishes the current flowing through this coil, it has the opposite effect upon the total armature current. At the same time the lag is diminished, and consequently the load on the machine is increased. This is but natural, since the energy wasted in the resistance $r$ must be supplied by the machine.

II.—*Resistance and Capacity.*

Figs. 5 and 6 refer to the series, and Figs. 7, 8, and 8A to the parallel arrangement. In Fig. 6 we start with the assumption that the condenser E.M.F. shall be 10,000 volts. This gives the current $I = \frac{500 \cdot 5 \cdot 10{,}000}{10^6} = 25$ amperes, and $E_R = 25 \times 100 = 2{,}500$ volts. Combining the two voltages, we obtain the E.M.F. of the machine, $E_A = 10{,}300$ volts. If the lamp-voltage were prescribed instead of the condenser voltage, we would proceed as here shown, and then expand or contract the diagram to bring the lamp-voltage to the required figure. It is interesting to note what influence a change in capacity has. The smaller the capacity the greater does the discrepancy become between machine E.M.F. and lamp E.M.F. The larger the capacity the smaller is this discrepancy, until with a condenser of infinite capacity (that is, the condenser replaced by a short, stout conductor), the machine E.M.F. and the lamp E.M.F. become equal.

Fig. 7 shows a condenser placed as a shunt across the mains. Assuming $E = 10{,}000$ volts, and $R = 100$ ohms, we have a lamp current of 100 amperes, and a condenser current of 25 amperes, provided $r = 0$. This is shown in Fig. 8, from which we find that the machine current is 103 amperes. Suppose now that $r = 200$ ohms, then we must modify the diagram as shown in Fig. 8A.

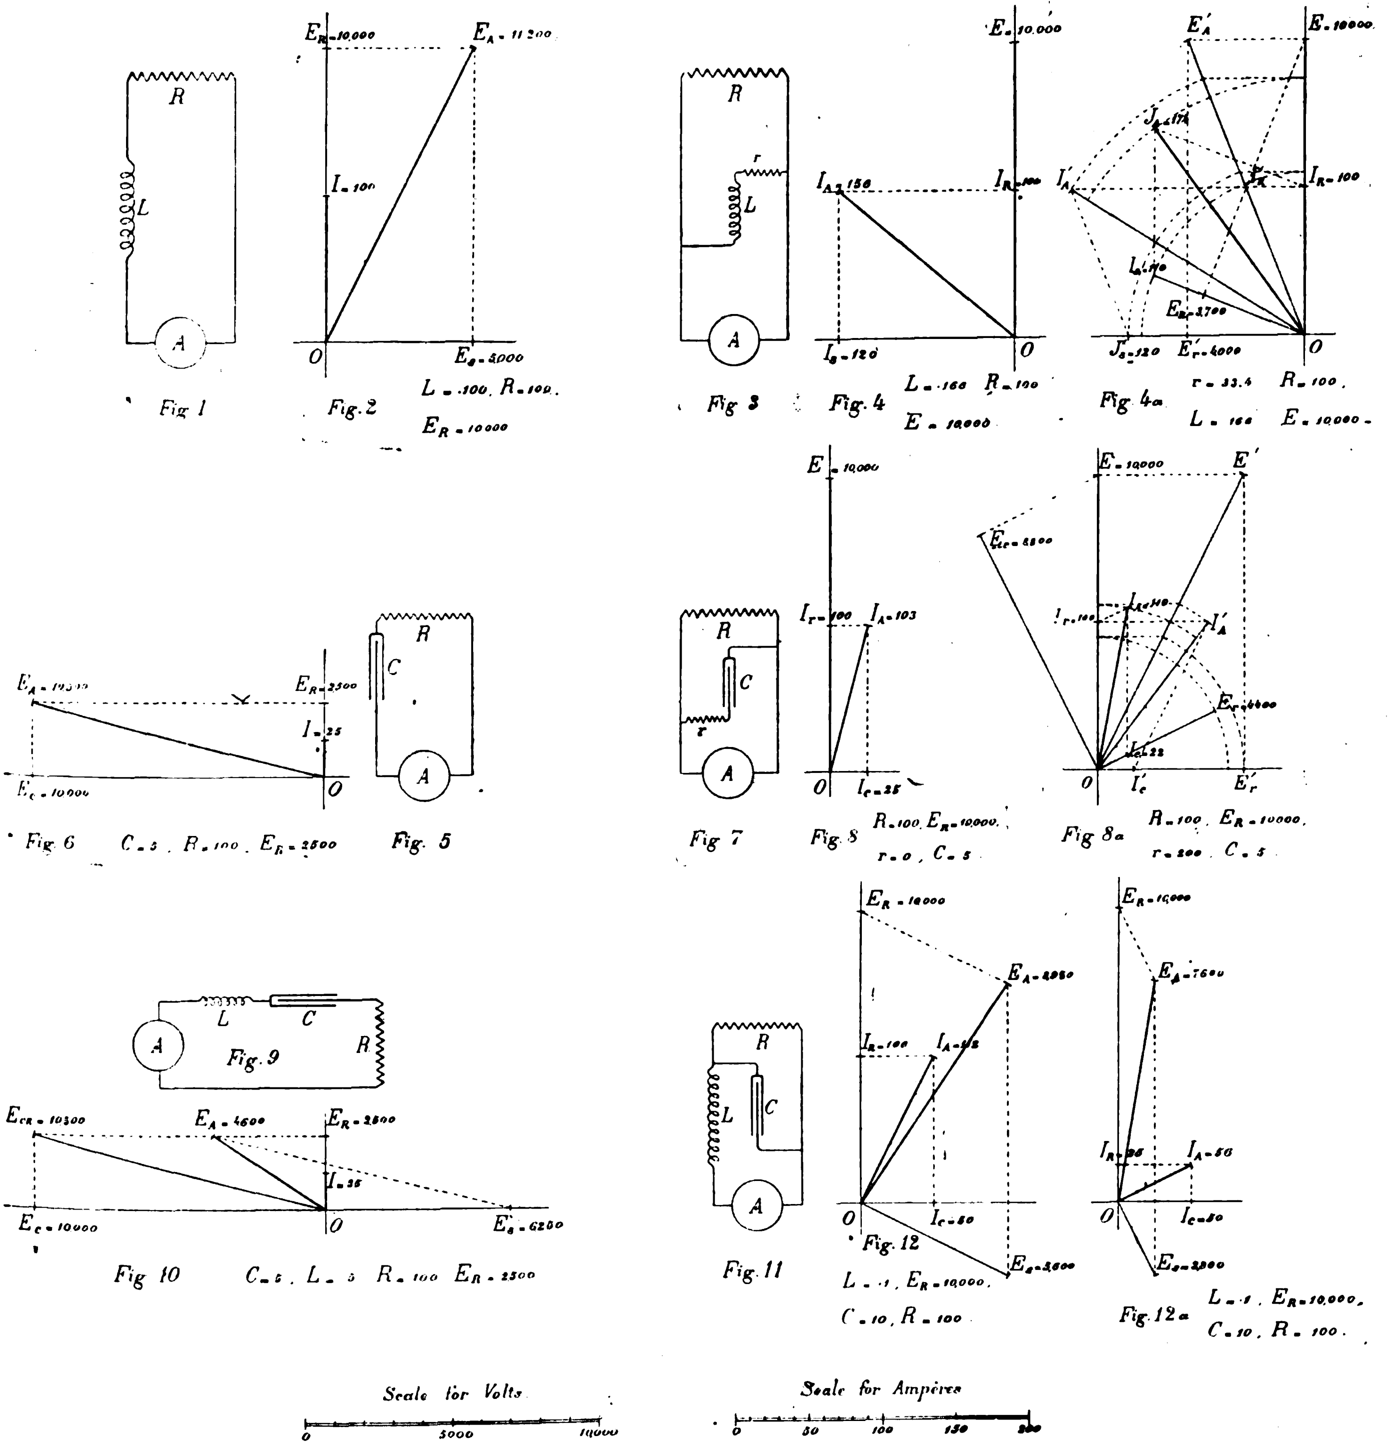
If the condenser current were the same as before it would be indicated by the length, O $I_c'$. At the same time an E.M.F. of 5,000 volts (O $E_r'$) would be required to overcome the resistance $r$. This, combined with $E = 10{,}000$, gives O $E^1$ as the machine E.M.F., which would be required under these conditions. The machine current would be O $I_A'$. But as by the terms of the problem the machine E.M.F., which is equal to the lamp E.M.F., is limited to 10,000 volts, we must contract the whole diagram in the ratio of O E to O E'. At the same time, and as a matter of convenience, we rotate the diagram through an angle equal to that between these two lines, and obtain by a simple geometrical process the true condenser current, as $I_c = 22$, and the true machine current, as $I_a = 110$ amperes. The condenser E.M.F. must stand at right angles, and to the left of the condenser current, and is 8,800 volts, as shown at $E_c$. By the introduction of the resistance $r$, we have, therefore, decreased the condenser current, but increased the machine current. We have also decreased the lag and increased the output of the machine, the additional power going to heat the resistance. It is important to note that in the cases considered up to the present the machine voltage is either equal to or higher than any other voltage in the circuit, so that we see that neither self-induction alone, or capacity alone, can in any way produce an increase of pressure, but such an increase may be produced if both are present in the same circuit, a case we now proceed to investigate.

III.—*Resistance, Self-Induction, and Capacity.*

In the arrangement represented by Fig. 9, a self-induction, a condenser, and a resistance are in series. Starting with the

Digitized by Google

assumption that the condenser E.M.F. shall be 10,000 volts, we get for $C = 5$ microfarads a current of 25 amperes. With a resistance of 100 ohms, this gives us a lamp E.M.F. of 2,500 volts. The machine E.M.F. required, if there were no self-induction, is as in Fig. 6 $E_{CR} = 10{,}300$ volts. But now we have a self-induction of ·5 quadrants. To force a current of 25 amperes through such a self-induction requires 6,250 volts, and this E.M.F. must be in advance over the current by 90deg. Thus we mark off to the right of the centre line the point $E_s = 6{,}250$ volts, and combinin this with $E_{CR} = 10{,}300$, we get the true machine voltage result will be that the current will increase to such a value as to absorb 2,500 volts in the smaller lamp resistance. An increase of current means, of course, a proportional increase in the condenser voltage beyond the 10,000 volts with which we started. Now suppose we reduce the lamp resistance to zero, then R will be simply the resistance of the mains; that is a very small amount, and consequently a very low machine E.M.F. will suffice for setting up an enormously high pressure in the circuit (always supposing $E_c = E_s$). Let us assume, by way of example, that R has been reduced to 10 ohms. Then



$E_A = 4{,}600$ volts. Here we have a case where the machine voltage is lower than some other voltage in the circuit, and it will be instructive to analyse it. In the first place, it will be clear that the lowest value which the machine voltage can assume equals that at the lamps. This represents the most dangerous condition of working, and it will be reached if $E_s = E_c$. If at the same time we lower the lamp voltage by reducing R, we must lower the machine voltage proportionately in order to keep $E_c$ at 10,000 volts. If we leave the machine voltage at 2,500, as in the diagram, the $E_R$ would be 250 volts if the current is to remain at 25 amperes. The E.M.F. induced in the armature of the machine would also be only 250 volts, and yet the pressure between the plates of the condenser would be 10,000 volts. If we increase the induced E.M.F. to 1,000 volts, the condenser E.M.F. would be 40,000 volts and so on. This particular condition of working, which is obviously the most dangerous possible, presupposes, however, that the E.M.F. of self-induction equals that existing between the plates of the condenser, or in symbols

$$L \omega I = E_c$$

Digitized by Google

Since $I = C E_c \omega 10^{-6}$ we have $E_c = \frac{I\,10^6}{C\omega}$ and $L\omega = \frac{10^6}{C\omega}$ from which we find the frequency for the most dangerous condition of working

$$\omega = 2\pi n = \frac{10^3}{\sqrt{CL}}$$

$$n = \frac{10^3}{2\pi\sqrt{CL}}$$

In the present case $C = 5$ and $L = \cdot 5$; inserting these values we find $n = 101$. If, therefore, we speed up the alternator so as to increase the frequency from 80 (which is the value assumed in all the diagrams) to 101, we shall work under the most dangerous conditions, and this is the case to which Mr. Swinburne referred in his remarks before the Physical Society, to which allusion has already been made in the first article. Although the condition of working here explained is the most dangerous, it is not the only dangerous condition, as can easily he seen by going back to Fig. 10. If we may neglect the resistance R (which is quite permissible, since it is merely the resistance of a heavy main), the point $E_R$ goes down very nearly to O, and the length $OE_a$ representing the E.M.F. induced in the armature of the machine, is very nearly equal to the difference between $E_c$ and $E_s$; in the case of the diagram 3,750 volts. This means that if we excite the alternator so that at the frequency of $n = 80$ it gives 3,750 volts on open circuit, and then join it with the main, the pressure on the main will be 10,000 volts. Whether the pressure on the terminals of the alternator will be 10,000 volts depends, of course, on the position of that part of the circuit which has the self-induction of ·5 quadrants. If this large amount of self-induction were all in the armature, then the terminal pressure would be 10,000 volts, but this is practically impossible. The self-induction of an armature is measured by hundreds not tenths of quadrants, and, therefore, to produce the case represented by Fig. 10 it would be necessary to put a special self-induction coil in circuit, or if not a simple coil, some device which adds to the self-induction of the armature, for instance, a step-up transformer. Even then the self-induction will be less than that which has been assumed in plotting the diagram, my object being, as already explained, not to represent any particular practical case, but such a case which will render it most easy to explain and analyse the various phenomena. The diagram has, therefore, qualitative but not quantitative importance. Bearing this in mind, let us now investigate what phenomena we have to expect in laying and testing a concentric main. The main itself is the condenser, and its resistance, taking the place of R, is very small; in fact, negligible with the small currents flowing when the far end is open. At the central station we have an alternator, and possibly a step-up transformer. If the latter be omitted L will be very small, and the effects represented by Fig. 10 will scarcely be noticeable, but with a step-up transformer in circuit L is somewhat larger, and the effects may become sensible. Even then, whilst the main is short, they will scarcely be noticed, for the capacity is then small, and consequently the condenser current is small. Now a small current flowing through even a sensible self-induction does not evoke any great back E.M.F of self-induction, and, consequently, the E.M.F. measured at the end of the main will be only insensibly greater than that corresponding to the excitation of the alternator. But as the operation of laying the main proceeds, the capacity of our condenser, and with it the condenser current, grows. In a like manner must the E.M.F. of self-induction grow, and, consequently, we find that the farther we proceed with the mains from the central station the higher becomes the condenser E.M.F., which we measure at the open end of the mains, or if we wish to keep this E.M.F. at its former value, we must reduce the excitation of the alternator.

The case represented by Fig. 10 is, however, not of any practical importance except in the laying and testing of mains. In actual work we have in addition to the condenser current also the current for working the lamps at the distant end, as represented by Fig. 11. This problem can also be easily solved by a diagram. Let in Fig. 12 $0E_R = 10{,}000$ represent the voltage at the far end of the main, and $I_R = 100$ the lamp current delivered under this pressure. If the capacity of the main is 10 microfarads, the condenser current will be $I_c = 50$ amperes. The armature current is therefore $I_a = 112$ amperes. Let $L = \cdot 1$, the E.M.F. of self-induction is $E_s = 5{,}600$ volts, and by combining this with $E_R$ we find the induced or machine E.M.F. $E_A = 8{,}950$ volts Thus we obtain 10,000 volts at the end of our main by exciting the alternator only to that extent which would give on open circuit 8,950 volts. The discrepancy becomes still greater if we reduce the lamp current to 25 amperes, as shown in Fig. 12A. There we have $E_s = 2{,}800$ volts, and $E_A = 7{,}600$ volts or 2,400 volts less than at the end of the main. It is necessary to remark that in reality the case is not quite so simple as represented by the diagram. We have at the far end of the line one or more step-down transformers which have self-induction. The result is that $I_R$ will be shifted to the left of the vertical. We have further some, though only a small amount of resistance in the main, and the condenser action, or, rather, the capacity, is spread all along the main instead of being concentrated at one point. We have also some resistance in those parts of the circuit having self-induction, and where more than one main is worked from one machine a certain correction is required to apportion the effect of the self-induction of the machine between the various mains. All these points can be treated graphically by an extension of the theory here developed. It should be noted that the figures given in the diagrams are convenient approximations.

## ON THE RISE OF ELECTROMOTIVE FORCE OBSERVED IN THE DEPTFORD MAINS.

BY R. T. GLAZEBROOK.

The following investigation will, I think, be found to contain the explanation of the curious effect discovered by Mr. Ferranti and described by Mr. Swinburne in his Paper before the Physical Society on December 12th. In it I consider the cable merely as a condenser. Since the wave length of the Deptford current is about 2,000 miles (*Electrician*, p. 205), it is clear variations in the potential at one end are propagated practically instantaneously to the other. The fall of potential along the cable which must exist when the current is flowing will not, I believe, seriously affect the result. I have not at present got the data for determining how far the self-induction of the cable comes in as an important factor; it is clear that this alone will not produce the effect, for it disappeared when a dynamo was substituted for the transformer.

Consider then two circuits, each having self-induction connected up in parallel with a condenser.

Let $L_1$ $L_2$ be the coefficients of self-induction of the circuits $R_1$ $R_2$ their resistances. Let C be the capacity of the condenser, Q the quantity of electricity on one plate at any moment, $i_1$, $i_2$ the currents in the two circuits, and suppose that in the one circuit there is a periodic electromotive force following the sine or cosine law, which we may denote by $E\,e^{\iota nt}$, where $\iota = \sqrt{-1}$. The full expression is $E\,e^{\iota nt} + E'\,e^{-\iota nt}$, and for the present we can work with the first term as typical. Then we have from the two circuits the equations

$$\left.\begin{aligned} &\frac{Q}{C} + L_1\frac{di_1}{Dt} + R_1 i_1 = Ee^{\iota nt} \\ &\frac{Q}{C} - L_2\frac{di_2}{dt} - R_2 i_2 = 0 \\ &\frac{dQ}{dt} = i_1 - i_2 \end{aligned}\right\} \quad . \; . \; . \quad (1)$$

Hence differentiating and substituting

$$\left.\begin{aligned} i_1 - i_2 + C\,L_1\frac{d^2 i_1}{d t^2} + C\,R_1\frac{d i_1}{d t} &= i\,n\,C\,E\,e^{int} \\ i_1 - i_2 - C\,L_2\frac{d^2 i_2}{d t^2} - C\,R_2\frac{d i_2}{d t} &= 0 \end{aligned}\right\} \quad . \; . \; . \quad (2)$$

Now assume

$$\left.\begin{aligned} i_1 &= I_1 \cos(n\,t + \epsilon_1) \\ &= J_1\,e^{int} + J_1^1\,e^{-int} \\ i_2 &= I_2 \cos(n\,t + \epsilon_2) \\ &= J_2\,e^{int} + J_2^1\,e^{-int} \end{aligned}\right\} \quad . \; . \; . \quad (3)$$

We need only deal with the first term in each case, and we can get the second term by changing the sign of $i$. We have also

$$\left.\begin{aligned} I_1 &= \sqrt{(J_1\,J'_1)} \\ i \tan \epsilon_1 &= \frac{J_1 - J'_1}{J_1 + J'_1} \end{aligned}\right\} \quad . \; . \; . \; . \; . \; . \quad (4)$$

Of course $J_1$ and $J'_1$ are complex quantities of the form

$$a + \beta\sqrt{-1}, \quad a - \beta\sqrt{-1}.$$

On substituting and dividing by $e^{int}$ we find

$$\left.\begin{aligned} J_1 - J_2 - C\,L_1\,n^2\,J_1 + in\,C\,R_1\,J_1 &= in\,C\,E \\ J_1 - J_2 + C\,L_2\,n^2\,J_2 - in\,C\,R_2\,J_2 &= 0 \end{aligned}\right\} \quad . \; . \; . \quad (5)$$

Hence

$$\left.\begin{aligned} &J_2(1 - C\,L_2\,n^2 + in\,C\,R_2) = J_1 \\ &J_1\left[(1 - C\,L_1\,n^2)(1 - C\,L_2\,n^2) - n^2 C^2 R_1\,R_2 - 1 \right. \\ &\quad \left. + in\{C\,R_1(1 - C\,L_2\,n^2) + C\,R_2(1 - C\,L_1\,n^2)\}\right] \\ &\quad = in\,C\{1 - C\,L_2\,n^2 + in\,C\,R_2\}\,E \end{aligned}\right\} \quad . \quad (6)$$

Writing down the values for $J'_1$ $J'_2$ in the same way we get the following expressions for $I_2$ and $I_1$.

$$I_2\{(1 - C\,L_2\,n^2)^2 + n^2\,C^2\,R_2^2\}^{\frac{1}{2}} = I_1 \quad . \; . \; . \; . \; . \; . \; . \quad (7)$$

$$I_2[\{R_1(1 - C\,L_2\,n^2) + R_2(1 - C\,L_1\,n^2)\}^2 + n^2\{C(n^2\,L_1\,L_2 - R_1\,R_2) - (L_1 + L_2)\}^2]^{\frac{1}{2}} = E \quad . \; . \; . \; . \; . \; . \; . \; . \quad (8)$$

The coefficient of $I_2$ may be written thus :—

$$[(R_1 + R_2)^2 + n^2(L_1 + L_2)^2 - 2\,C\,n^2\{R_1^2\,L_2 + R_2^2\,L_1 + n^2(L_1 + L_2)L_1\,L_2\} + C^2 n^2(R_1^2 + n^2 L_1^2)(R_2^2 + n^2 L_2^2)]^{\frac{1}{2}} \quad . \; . \quad (9)$$

This expression becomes the denominator of E in the value of $I_2$. When C is zero it is limited to the first line.

Now, it is clear that for small values of C, the term in C with a negative coefficient is more important than that in $C^2$, that is, the introduction of the condenser at first reduces the value of the denominator, and so increases the value of $I_2$. As the capacity of the condenser is increased, the denominator continues to fall in value, reaching a minimum when

$$C = \frac{R_1^2\,L_2 + R_2^2\,L_1 + n^2(L_1 + L_2)\,L_1\,L_2}{(R_1^2 + n^2\,L_1^2)\,(R_2^2 + n^2\,L_2^2)} \quad . \; . \quad (10)$$

For this value of C and for certain values of $n$, $R_1$, $R_2$, $L_1$, $L_2$, this minimum value of the denominator may vanish, since in the first form the expression is the sum of two squares it can never be negative.

Thus, as C increases from zero to the value just given, the value of $I_2$ increases, and may even under certain circumstances become infinite.

This circumstance will perhaps explain the difficulty met with by Mr. Mordey (*Electrician*, p. 214), the various coils of the armature will have a condenser action of the kind attributed to the cable.

As the value of C is still further increased, the denominator increases from its minimum value until when C has just double the above value, and becomes equal to

$$\frac{2\{R_1^2\,L_2 + R_2^2\,L_1 + n^2(L_1 + L_2)\,L_1\,L_2\}}{(R_1^2 + n^2\,L_1^2)\,(R_2^2 + n^2\,L_2^2)} \quad . \; . \; . \quad (11)$$

the terms in C disappear, and the condenser is without affect.

Thus, so long as C lies between zero and value last given, the current in the second circuit is increased by the condenser. For values of C greater than the above, the denominator is increased, and the condenser tends to reduce the value of $I_2$.

This critical value (as it may be called) of the capacity depends on $n^2$, though unless the self-induction is so large that $n$ L is comparable with R, changes in the value of $n$ will not have very great effect.

The greatest change which can take place in the denominator is given by

$$\frac{n^2\{R_1^2\,L_2 + R_2^2\,L_1 + n^2(L_1 + L_2)\,L_1\,L_2\}^2}{(R_1^2 + n^2\,L_1^2)\,(R_2^2 + n^2\,L_2^2)} \quad . \quad (12)$$

and this, of course, depends directly upon $n$. Thus the effect of the condenser will be more marked with rapid alternations than with slow ones. It would be interesting to see how far the above theory agrees with the results obtained by Mr. Ferranti by substituting in the various expressions the values of the resistances, self-inductions, and capacity which he used, the length of cable for which the effect would vanish might then be found by calculation. The quantities, $\epsilon_1$, $\epsilon_2$, which give the lag behind the E.M.F. for the two currents respectively can be written down without much difficulty, but it is hardly necessary to do this. It will be noticed that all the above expressions are simplified if either of the two self-inductions vanish. Thus, to produce the effect, it is only necessary to have self-induction in one of the two circuits.

I hope shortly to arrange some laboratory experiments to test the above theory, which, I think, accounts in a general way for most of the observed facts, though I am fully sensible of its incomplete nature. There would be no very serious difficulty in treating the problem completely so far as the cable is concerned. Much of the work for this has been done already by Prof. J. J. Thomson, and I think also by Mr. Heaviside, but I doubt if the gain resulting from this alone would be very great. There remains, however, the question as to what effect the electrostatic capacity of the transformers produces. This problem is, I fear, at present beyond the range of analysis, though some indications of the effect might be developed. The introduction to Mr. Kapp's Paper (*Electrician*, p. 197) seems to indicate that his solution of the problem is the same as that just given. I worked out the above results for my own satisfaction on reading Mr. Swinburne's Paper, with the discussion on it, and it may be of interest to have the solution given in various forms.

---

**The Dissociation of Carbon Dioxide Gas by the Electric Spark.**—An interesting paper, says *Nature*, is communicated by Prof. von Hofmann to the current number of the *Berichte* upon the dissociation of carbon dioxide gas into carbon monoxide and oxygen by means of the electric spark. Dalton and Henry long ago showed that carbon dioxide, although formed by exploding a mixture of two volumes of carbon monoxide with one volume of oxygen by the passage of an electric spark, is again partially decomposed into carbon monoxide and oxygen by the continued passage of the spark. Prof. Hofmann has now determined the exact conditions under which the explosive recombination occurs. The most suitable distance apart of the platinum terminals appears to be between two and a-half and three millimetres, and Prof. Hofmann advises the use of adjustable terminals rather than the ordinary platinum wires fused into the side of the eudiometer. A Leyden jar in the circuit renders the occurrence of periodical explosions more certain. The spark should also pass at about a quarter the height of the gas column instead of, as usual, near the top. The current itself, moreover, should not be too strong; that from two Bunsen cells and only a moderate sized Ruhmkorff coil yields the best results. It is also preferable to use a volume of carbon dioxide, previously dried over sulphuric acid, not exceeding ten cubic centimetres at a pressure of 650-700 mm. Under these conditions the first explosion usually occurs in about 15-20 minutes. The second and succeeding explosions occur after shorter intervals than the first. This experiment is certainly one of the most interesting in all the range of dissociation phenomena.

## TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has by far the largest circulation of any English Electrical paper, and circulates all over the World.**

*Particulars relating to Advertisements will be promptly forwarded on application to the Offices as above.*

TRADE ADVERTISEMENTS *intended for the current issue must reach the Offices not later than First Post on Thursday morning. Renewals of expiring advertisement orders and alterations to standing advertisements should be in the Publisher's hands by Wednesday at latest. No alteration can be made in Wrapper advertisements after Wednesday evening.*

SMALL PREPAID ADVERTISEMENTS *(for Rates see page xvii.) are accepted up to 4 p.m. on Thursday.*

## TECHNICAL PRINTING.

"THE ELECTRICIAN" PRINTING AND PUBLISHING COMPANY (LIMITED) *inform Electricians, Electric Light Engineers, &c., that they make a specialty of Technical Printing, and have a large Staff thoroughly acquainted with Electro-Technology. They can, therefore, promise Accuracy and Despatch in the Printing of Electro-Technical Literature, &c.*

## "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. (Royal 8vo.)

*Early in each year is issued* "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. *The* DIRECTORY *was established in 1883, and the 1890 Edition consisted of about 850 pages of printed matter. The names and addresses of all persons engaged in the Electrical Industries at home and abroad may be relied upon as accurate. Useful Tables and Electrical Formulæ, and information specially compiled for this work are given, together with popularly-written Biographical Notices of the leading Electricians, Electrical Engineers, &c., accompanied in many cases by Portraits.*

*Orders for the 1890 issue should be forwarded* AT ONCE *to the Publishing Offices, Salisbury-court, Fleet-street, London, E.C.*

*The 1891 Edition is now preparing, and New Names, &c., can now be received.*

## ELECTRICAL BOOKS AND PUBLICATIONS.

*All Books, Newspapers, and other publications, dealing with Electrical and kindred subjects, can be ordered direct of "*THE ELECTRICIAN*" Printing and Publishing Company, who are proprietors of the well-known "*ELECTRICIAN*" Series of Standard Electrical Works, and re agents for all the leading publishing houses at home and abroad.*

## LAPSE OF THE TELEPHONE PATENT.

Time brings round its revenges, even to the point of throwing open to public use the most jealously guarded of monopolies. Rarely in the history of patent law has any monopoly been upheld in a more merciless manner than that of the electric telephone. All the arts of legal intimidation, of buying up powerful rivals and bullying weaker ones, terrorising them with legal injunctions and persecuting them with legal costs, mercilessly exacted to the last legal farthing, have been resorted to in order to keep the great monopoly upon its throne. Company has succeeded company: lawsuit has followed lawsuit: one network after another has spread its ramifications over the great commercial centres, until the capital invested has grown into millions.

Now that the great telephone monopoly has come to its legal end, it is possible to review the chequered career of the invention. Without going back into the ancient history of the crude attempts made with more or less success before the year 1875 to bring out an electric telephone, we need only refer to the scientific journals of that time to discover that, as is the case with almost all great inventions, the subject was "in the air," waiting only to receive definite shape and name. In that year three or four electricians were at work on this very problem. In England there was VARLEY, in the United States ELISHA GRAY and ALEXANDER GRAHAM BELL, and, if all the affidavits in American patent cases are to be credited, at least three or four other inventors, including the notorious DANIEL DRAWBAUGH. At the end of that year GRAHAM BELL had worked out a system of harmonic telegraphy of a novel kind, dependent on the use of alternating or undulatory currents, and was preparing to put it into shape for patenting. It does not appear that undulatory currents were essential for the purpose in view, but that they *were* undulatory determined the ultimate success of the telephone. However, BELL's reasons for preferring them to an intermittent current were; that a larger number of telegraphic signals could be transmitted simulta-

Digitized by Google

neously, that for cable work dispatches might be transmitted more rapidly than by intermittent currents, as it was unnecessary to discharge a cable before a new signal was made; and lastly, that as the current was never broken, a spark arrester became unnecessary. VARLEY, on this side of the water, was also working at the transmission of harmonic signals. These harmonic telegraphs were called telephones, though the word telephone had previously been appropriated for an instrument that was not intended in the least as a harmonic telegraph.

ELISHA GRAY, on the other hand, was endeavouring to devise an articulating apparatus that should not be a telegraph at all, but a real speaking telephone. VARLEY'S telephone, after an ignominious failure at the now defunct Queen's Theatre, came to nought. And, as fate ordained, ELISHA GRAY'S speaking apparatus, and GRAHAM BELL'S harmonic telegraph working by alternating currents (induced by vibrating a tuned armature in front of an electro-magnet), were brought on the same day—February 14, 1876—to the United States Patent Office. Here begins a conflict of evidence as to what occurred: for the official of the Patent Office who received both communications has sworn that he revealed the invention of one party to the other; whilst in a subsequent affidavit he has sworn that his former declaration was made whilst under the influence of alcohol. Comparison of the original documents is interesting. It shows that ELISHA GRAY distinctly claimed, and illustrated by drawings, apparatus for transmitting articulate speech. "It is the object of my invention," he says, "to transmit the tones of the human voice through a telegraphic circuit, and reproduce them at the receiving end of the line, so that actual conversations can be carried on by persons at long distances apart." It shows also out of GRAHAM BELL'S own mouth what at that date he had, and what he had not invented. "Be it known," he begins, "that I, ALEXANDER GRAHAM BELL, of Salem, Massachusetts, have invented certain new and useful improvements in telegraphy." "My method of multiple telegraphy"; "The advantages that I claim are . . . that a very much larger number of signals can be transmitted"; "that cable despatches may be transmitted more rapidly than by means of an intermittent current"; "when a cylinder, upon which are arranged bar magnets, is made to rotate in front of the pole of an electro-magnet, an undulatory current of electricity is induced in the coils of the electro-magnet"; "a number of instruments may be placed on a telegraphic circuit . . . when the armature of any one of the instruments is set in vibration, all the other instruments upon the circuit which are in unison with it respond." The foregoing are samples from the body of the specification, and obviously have reference to telephones of the VARLEY order, not to articulating instruments. After a casual remark that there are other uses for these instruments, such as the telegraphic transmission of noises or sounds of any kind, the specification proceeds to the following, the only passage in it which can be construed into a reference to articulate speech:—"One of the ways in which the armature may be set in vibration has been stated before to be by wind. Another mode is shown in Fig. 7, whereby motion can be imparted to the armature [shown as a tuned vibrator or lever] by the human voice or by means of a musical instrument." This passage, coming in the middle of a specification on harmonic telegraphy, with no other explanation, can only mean that dot and dash might be transmitted to the vibrator by means of the voice or by a musical instrument. However it is not upon this passage but upon the instrument constructed by BELL that the monopoly of the American Bell Telephone Company has been practically built up, and hangs to-day. It appears, then, that ELISHA GRAY'S object was to transmit articulate speech, while it seems probable that GRAHAM BELL had no such aim, since he did not allude to it in his patent. But as the intentions of the inventors differed, so, too, did the capabilities of their inventions; but, strange to say, the difference was one which gave to him that asked not, and denied success to the man who conceived the idea. ELISHA GRAY expressed his *wish* to make his instrument talk; GRAHAM BELL at once grasped the idea that his *could* talk; and he made it talk.

ELISHA GRAY, beaten in the first round of the judicial fray, fell into the background. At the Centennial Exhibition both inventors showed instruments, and by this time BELL had dropped the tuned armatures and rotating bar magnets, and all the paraphernalia of multiple telegraphy, and his instrument had developed into an articulating telephone. The enthusiasm was immense, particularly about BELL'S instrument. Sir WILLIAM THOMSON, the leading juror of the electrical section, wrote an official report, narrating how in this instrument he heard the words:—"To be, or not to be; there's the rub" (a misquotation, it will be noted, of the well-known passage in Hamlet), uttered by a thin disc of iron which was held down all round by being magnetically attracted to an electro-magnet with an external iron tube; that being the form of instrument used as receiver. A pair of instruments he himself brought back and a showed publicly in Glasgow in September of that year, though he failed to make them work, apparently having neglected to apply a sufficiently powerful battery to cause the iron disc of the receiver to be held down by the electro-magnetic attraction.

Three months after this publication of the great invention, GRAHAM BELL filed the specification of his English patent, which has just expired. How any patent could be valid under such circumstances must ever remain a legal mystery. By this time the phrase "by the human voice," which was the solitary suggestion of the American specification capable of being construed as implying a speaking telephone, had been enlarged and expanded into a lengthy description of a speaking instrument. An elegant device for getting rid of a battery from the line circuit had also been imported as a novelty. When in 1882 this matter came into legal question it was held that the only two novelties of the December patent were holding down the iron disc (which it mis-describes as a steel plate) all round, instead of attaching it at one corner, and devising a new sort of electro-magnet, having permanent magnetism in the core—an invention for which, by the way, an eminent British electrician had been refused a patent in 1870 on the ground of want of novelty. Yet on these two pleas the BELL patent was upheld, first in an action tried in Edinburgh before Lord MACLAREN, then in London before Mr. (now Lord) JUSTICE FRY, and finally before the late Sir GEORGE JESSEL in the Court of Appeal. We do not intend to investigate the precise manner in which the credit for this invention should be given. Indeed, it is doubtful whether there was not, as far as GRAHAM BELL was concerned, a discovery rather than an invention. The discovery lay in the fact that the multiple telegraph instrument would talk.

Why then did ELISHA GRAY, who was an inventor and patentee, drop out of the running? This is the old question which is ever turning up in any industry where progress is being made. Shall credit be given to a man whose imagination and inventive faculties enable him to sketch and describe an instrument or device which shall achieve certain ends? No; we have too many such, they must do more than that. ELISHA GRAY did more. He made a talking telephone. But that is not all. Some would say let him patent it, and the credit shall be his. But even this he did. Why, then, is BELL'S name known in every civilized country while hundreds of thousands of the carefully-developed form of his telephones

Digitized by Google

are in daily use. Why is it that not nine out of ten of our readers could not describe ELISHA GRAY'S telephone? It is merely because GRAHAM BELL pushed, knew how to push, and succeeded in pushing, his telephone on to the market.

It is nevertheless sad to think how much activity has been crushed out of the electrical industry by this decision. One has only to look at the progress telephony has made in such countries as France, Sweden, and the South American Republics to see what might have happened here in England had the patent law not stepped in to arrest the hand of progress. Our patent laws were never framed to enable a patentee to build a huge monopoly upon an invention which, whether BELL really invented it or not, was in the possession of the public months before his patent was even applied for. That which happened in the case of the now expired BELL patent, though, unfortunately, not quite a unique experience, ought never again to be permitted to occur to the detriment of a whole industry.

## REVIEWS.

**The Art of Electrolytic Separation of Metals.** By G. GORE, LL.D., F.R.S. (*The Electrician* Printing and Publishing Company, London.)

Only those who have had to do with the industrial application of electrolysis to winning and refining metals can fully appreciate the need for a treatise dealing with the subject comprehensively. Information scattered through the pages of technical journals or existing as tantalising scraps in books on electro-deposition applied to the protection or reproduction of articles having a value apart from the material coating or forming them, has hitherto been all that was available—at least for the English reader. Any attempt, therefore, to fill the gap and provide us with a reliable compilation of existing knowledge is thoroughly meritorious. But Dr. Gore has produced a book which has other claims to consideration than that of supplying a real want, and which may be praised for its intrinsic qualities. Starting with an "historical sketch," mercifully brief, the "theoretical division," devoted to the exposition of the data and phenomena that must be known and understood to gain a clear insight into the causes and conditions governing the electrolytic separation of ions, is soon reached, and some 140 pages allotted thereto.

Nothing is more necessary than a complete grasp of the principles that underlie what is by no means an easy art, but it is questionable if it is wise to occupy considerable space with such matters as explanations and definitions of current electromotive force and chemical affinity. They are of necessity dealt with briefly, so that one ignorant of the subject would find the mental food rather too concentrated for comfortable digestion, while they are not needed by the electrolytician (to coin a name for the electro-chemical expert), as they form the very basis of his knowledge. Such subjects are better learned from books dealing with them exclusively. The same remark applies to much of "Section F" (for which Mr. Guy C. Fricker is responsible), which appears to us somewhat superfluous. But where the "theoretical division" touches upon *electrolysis*, as distinct from both *electricity* and *chemistry*, it is perfectly in place, and the subject being handled deftly, and in a manner eminently sound, it is in every way welcome.

On turning to the "practical division," there is first an excellent summary of the *pros* and *cons* that have to be considered before embarking on the establishment of an electrolytic copper refinery, which may be commended to those about to start such an enterprise. Hitherto but few successful attempts to reduce or refine other metals than copper on a large scale and make the process pay have been made, and the greater part of the next hundred pages is concerned with this material. Wherever the author treats of the energy relatively to a given reaction, he is always particularly lucid and accurate, and it is quite in keeping with the rest of his work to find him draw a clear distinction between the consumption of energy needed to actually reduce a metal from one of its salts and that required merely to transfer it from anode to cathode, if the former consist of the metal to be refined in a free state. He never, however, falls into the opposite error, and underestimates the waste due to non-essential causes, such as resistance of the electrolyte or corrosion and re-solution of the deposited metal. Among other qualities which differentiate this book from many slipshod productions, is the hearty goodwill with which certain popular fallacies are exploded. The purity of electrodeposited copper has long been an article of faith with the semi-ignorant, but, as Dr. Gore rightly points out, its degree of purity depends on the conditions of deposition, and may leave much to be desired.

Many very useful statistics are given of installations actually at work, the statements received from those interested in them being wisely indicated by quotation marks.

Although copper naturally occupies the largest amount of space, other metals are not overlooked, the separation of silver, lead, antimony, aluminium, zinc, magnesium, and the alkali metals being treated of fairly adequately. With regard to aluminium the Cowles process is mentioned, and is stated to depend probably on electrolysis as well as the production of an extremely high temperature, a view thoroughly consistent with the teachings of thermo-chemistry. Electrolytic methods for the extraction of the precious metals from their ores are discussed briefly at the end of the book, but the author preserves a judicious silence as to their success.

Sundry small errors call for notice. "Cuprous" is persistently misspelt "cupreous"; the atomic weight of platinum is erroneously given as higher than that of gold; the misleading Gallic term "metalloids" for "non-metals" is employed; "etherial" stands for "ethereal" on p. 136; and on p. 266 the zinc process for desilverising lead is credited to Pattison instead of Parkes. But these are trivial matters, and may be readily corrected in the second edition of what is a useful and valuable book. B. B.

## NOTES ON DYNAMOS.

The designing of continuous-current dynamos is settling down into two or three definite lines, and we rarely hear of any great or novel improvement. It is manifest that no considerable gain in efficiency is possible at full load, though something remains yet to be done in reducing the internal losses when the output is reduced. There is an obvious tendency to attach less importance to the economy of large dynamos on light loads, since it is a very common practice in supply stations to put down or to make provision for about ten or twelve machines, the idea being that one at least will be always loaded, and that, as the demand rises and falls, the dynamos are switched in one by one, so that theoretically all shall be under full load, except perhaps the last. But does this take place in practice? We think not. There is a tendency rather to distribute the load evenly among machines that are running, and it is generally supposed that no loss of economy is likely to arise by doing so. With exact distribution, the degree to which the dynamos are loaded would depend merely on the number at work, and we are inclined to think from what we have seen in the stations of the London supply companies, that for a considerable portion of the lighting hours the dynamos are working considerably below their full load. If this is the case, it would be well to pay a little more attention to the efficiency at reduced outputs, and endeavour to reduce the internal losses.

But in doing this, it must be remembered that with the modern practice of associating each dynamo with its own engine, and dispensing with counter-shafting, the economy of the engine must be considered from the same point of view. And there is a very serious and rapid decrease of efficiency in some engines, a decrease, in fact, which under the circumstances makes that of the dynamo of very secondary importance. According to the theory of design of these stations with their rows of dynamos and engines, this question is ignored, for it is supposed that all are fully loaded except, per-

Digitized by Google

haps, one. But a large engine such as those at the Stockwell depôt of the City and South London Railway, where the load is ever varying, but with far too great rapidity and irregularity to allow any switching in of machines, appears to offer advantages which have been somewhat neglected. One of the prominent features of these engines are their large and elaborate, though not complicated, governors, and next to these, the link gear to which they are attached is very noteworthy. In such an engine there may be a constant loss of energy due to friction, and an additional loss probably much smaller, which is a function of the load. But the steam consumption itself is closely regulated, and the losses due to wire drawing and other evils which arise as it were within the cylinder and passages, may be controlled by a good valve gear, and may be very approximately proportional to the horse-power delivered.

The question, then, resolves itself into one of cost of running; the mechanical excellence of both systems leaves little to be desired. The great differences which are to be found in the nature of the output of stations in different parts of London, differences which affect the average hours of lighting, the period of the maximum and the duration of the high load, together with the day work, would make comparison very difficult. We hope that by the time the Chamber of Commerce scheme for interchange of information has got under way, sufficient knowledge will have been gained on this point to enable the matter to be carefully analysed.

Though the connection between engine and the dynamo is very intimate where we are considering efficiencies, there are several points which are peculiar to the latter, and have but little to do with the motive power. One of these is the manner in which the field magnets are excited.

In central station work with continuous currents the shunt coils are generally fed from the mains through resistances which can either be adjusted singly, or which may be altered as a whole to control the entire station or separate feeders. The use of feeders—especially if the demand is irregular, or if it occurs in such a manner that first one part of the district and then another draws upon the supply—has prevented the use of ordinary compound wound dynamos, and unless any station for the supply of continuous current is erected on the principle of the few large units used at Deptford, the compound dynamo is likely to be used only for isolated plants or for such purposes or transmission of power as at Stockwell. Compound dynamos are sluggish in their response to sudden variations, but these do not as a rule occur in station work unless in connection with the supply to theatres. We have an interesting communication from a correspondent on this subject which we hope to publish next week.

The mode of calculating compound-winding has arrived at a settled condition. The theoretical men did their best to advance what seemed to them to be a mere matter of a few formulæ, while the dynamo builders, finding those few formulæ to be rather more ornamental than intelligible, used to try their machines with temporary coils under separate excitation, which could be measured, and on which the simple calculation of the winding could be based. Those fortunate firms who found it practicable to confine themselves to a few standard sizes were soon able to rely on previous experience, and only when an odd size, or an exceptionally large machine had to be built, did they resort either to a guess, or to the old way of making a preliminary excitation test. Most builders who have any pretensions to scientific methods have now arrived at some working formulæ of their own, and, needless to say, these are largely based on the work of the brothers Hopkinson. Dr. Louis Bell, in a recent Paper read before the American Institute of Electrical Engineers, put forward a *résumé* of the different systems of calculation in use, and developed a modification of his own. He divides the calculation into three terms, two of which are obtained from a permeability curve of the magnet iron, assuming that the density in the iron is known from the calculation of the shunt-winding. Thus he finds the magnetising force required to compensate for the fall of volts over the armature and series coils. The third term gives the magnetising force required to counteract the demagnetising effect of the armature. This term includes the leakage of the stray field. It is a question whether it would not be more satisfactory to calculate the characteristic curve in the well-known way, and from this find the ampere-turns needed in the two windings. This can easily be done from the data required for Dr. Bell's method, namely, the leakage, the permeability curve of the iron, and the dimensions of the machine. From this the ampere-turns for full load and for open circuit can be obtained, the difference giving the series turns, to which must be added sufficient ampere-turns to compensate for the demagnetising effect of the armature. This latter term has an element of uncertainty, for a good deal depends on the setting of the brushes. It is, however, best to allow a margin, as a volt or two of over-compounding is always advisable, even with the most regular speed, while under-compounding is an evil that should always be avoided.

## SHAKING THE FOUNDATIONS OF SCIENCE.*

During the past twenty years there has been gathered together round the site of the 1862 International Exhibition a national collection of museums and schools for instructing the people in art, natural history, and in pure and applied science. For a time a senseless howl was raised that the whole thing was a mighty job to benefit a few, and the antagonism reached its climax when it was proposed to celebrate the year of the Queen's Jubilee by erecting the Imperial Institute on the "inaccessible" spot at which so many millions from all parts of London—nay, from all parts of Great Britain—had congregated to study fishes and food, microbes and music, inventions and instantaneous illuminations, the colonies and coloured fountains.

At length the more sensible of the critics began to realise that the supposed sinecurists at South Kensington were enthusiastic workers who, had they devoted their intellectual powers to the common occupation of enlarging their balance at the bankers instead of to the uncommon occupation of enlarging our knowledge of Nature, would have become capitalists whose vested interests would have been deemed more sacred than life or honour. As it is, the hosts of Mammon now threaten the domain of science in Exhibition-road, for it is actually proposed to make an underground railway, with trains running at frequent intervals, right under Prof. Rücker's laboratory, right under Prof. Norman Lockyer's observatory, and skirting the electrical research laboratories of the City and Guilds Technical College, called the Central Institution.

The English nation (for what concerns the development of our science concerns the nation at large) must abandon its oft-boasted claim of being a practical people. Germany will laugh us to scorn, France will hit us with an epigram, and Italy will view us with polite amazement. To the Royal College of Science come from all parts of our country science teachers to be taught; to the Central Institution come, in addition to English lads, graduates from colleges in Europe and America to learn how England teaches the application of science to industry. Shall they come to find a rumbling earthquake led from early morn to late at night close to the foundations of the very pillars that have been erected at considerable cost in order to secure for the instruments placed on them freedom from even the vibration caused by passing footsteps? On concrete foundations, some 13 feet below the level of the street, rest many pillars of 9 feet square, each quite separate from its neighbour and from the floor on which the students stand; and the upper portion of each pillar is stuffed with a thick cushion of wool, so that the instrument resting on it may give as unwavering a decision as does the Lord Chancellor on the woolsack.

And even this is not sufficient to secure all the quiet that Urania loves, for, just as earthquakes are foretold by the fluttering of the wings of birds, so the approach of a cart at the other end of Exhibition-road is foreshadowed, long before it can be heard, by the uneasy trembling of the very delicate galvanometer needles. Hence must Urania's attendants, the students engaged in research, worship at her shrine by night; and woe

* From *Nature*.

Digitized by Google

betide them if they happen to assemble when a "small and early" is held in Exhibition-road; for then must they cover their heads and mournfully depart, persecuted by the rolling brougham, heartbroken by the rumbling growler, and driven to despair by the rattling hansom. Even at the Cavendish Laboratory, in a quiet back street in the peaceful University town of Cambridge, Lord Rayleigh's most accurate work on the electric units had to be done at night; and Wheatstone's galvanometer magnetic needles at King's College followed the penny iron steamers during the day rather than the electric currents he was measuring.

Judge, then, what will be the effect of passing trains, even though they be drawn by no

"Kittle of steäm,
Huzzin' and maäzin' the blessed ground with the Divil's oän teäm,"

on the telescopes in Exhibition-road, which, besides other work, by long-exposure photographs have discovered for us new stars never yet seen in telescope by human eye; or on the galvanometers, whose ray of light aids all electrical industries by pointing out electric flaws in glass and porcelain which the microscope would mistakenly pronounce perfect.

England has just given the Rumford Medal to Prof. Hertz, of Bonn, for his splendid work on electro-magnetic radiation. Will England allow the short-sighted policy of Mammon—

"Mammon the least erected spirit that fell from heaven"—

to prevent Prof. Boys continuing his work on the same subject at South Kensington? We honour Cavendish for weighing the earth; and now, when Boys has discovered how to hang bodies (not human) by quartz fibres, and so to weigh the earth with far greater accuracy than Cavendish could have done had his attracting balls been the size of houses, shall Boys be prevented from using his own apparatus? Shall the analysis of alternate-current waves at the Central Institution be interfered with by other waves set up by the new burrowing earthworm? We can hardly think so, when we remember how even a dear old soul has just received the news that an underground railway is to run close against our national science schools and laboratories. She, like Huxley's chum Gallio, cares for none of these things, but she had the sense to observe promptly, "Why, it will make all the things wriggle inside."

To study one set of vibrations in the laboratories in Exhibition-road, when another disturbing set is super-imposed by the vibration of the building itself, will be like listening to a violin solo when a brass band is braying in the neighbourhood. A prince, the Duke of Edinburgh, renowned for his musical skill, and distinguished as a violin-player at the Albert Hall close by, might fitly take the lead in jealously preserving the possibility for scientific research, the importance of which his father would have been the first to recognise. Urania's voice is like Cordelia's, "ever soft, gentle, and low," and catch it the student never can if his beams of light when moving across his galvanometer and electrometer scales begin

"To trip it as they go
On the light fantastic toe."

Radio-micrometers, magnetometers, and every other meter the motion of whose index must be greatly magnified, will become simply museum specimens, illustrating the blindly commercial enterprise of Englishmen, who removed from Trafalgar-square the statue of Jenner, because he only showed us how to save countless lives in every country, and was not distinguished, like the people whose statues remain, by killing many to add to England's landed estate. The 3ft. telescope now being erected in Exhibition-road will, of course, become useless when the earth-shaking train goes whirling underneath it. Why not leave it at once, like a broken monumental column, to mark the spot where lies buried many a noble hope?

But those who know, from past experience, how "great effects from little causes spring," already ask whether the scientific education of many, and the carrying on of scientific researches, such as have already been conducted in the laboratories in Exhibition-road, may not be worth more to the nation than any number of twopenny-ha'penny railway fares.

And others, whose only claim to be heard is the possession of that rarest of all senses—common sense—ask, Can it be possible that the nation, after having spent such vast sums on the erection and equipment of these laboratories, will now permit them to be rendered well nigh useless?

To move the laboratories of applied science is as undesirable as it is now impossible. Lord Carlingford, at their opening, congratulated the nation that a site had been selected for them close to the Museums, and stated that the French had even just moved the École Centrale of Paris, so that it might be placed in close proximity to the Conservatoire des Arts et Métiers. It is not likely that we shall now reverse our policy, divorce our schools from our Museums, and in securing such a result, waste all that has already been spent. If a railway is needed between South Kensington and Tyburnia, let it go under Queen's Gate, and not "round by the Serpentine under the trees," as sung Lord Algernon. The muse utters a cry of distress, let us join with her in shouting—

"Procul, oh! procul, este profani."

## ELECTRO-MAGNETIC MECHANISMS.

### PRESIDENTIAL ADDRESS TO THE JUNIOR ENGINEERING SOCIETY.

BY PROF. SILVANUS P. THOMPSON, D.SC., B.A.

*Introductory.*

To the mechanical engineer the study of the electro-magnet presents many interesting problems. By its means power transmitted electrically along a conducting wire produces a mechanical motion. The conditions of that motion constitute in one sense a purely mechanical problem, though the electric and magnetic conditions under which the power is supplied, and upon which the motion depends, belong to electrical science.

Consider at the outset in what an electro-magnet consists. The magnetic portion of it usually comprises two parts, a fixed iron core, straight or bent, and a movable piece of iron called the armature, the two being themselves portions of a magnetic circuit. The electric portion of it is a coil of insulated copper wire, usually encircling the iron core with numerous convolutions. When an electric current is switched on in the copper wire it produces upon the iron core a magnetic action. The magnetising force of the coil is strictly proportional to the electric current that is flowing in the wire and to the number of convolutions which that wire makes around the magnetic circuit. But the amount of magnetism induced in the core is not simply proportional to the magnetising force alone: it depends also upon the perfection or otherwise of the magnetic circuit. If the magnetic circuit constituted by the iron core and its armature and the intervening air-gaps is of insufficient cross-section, or of poor quality of material, or of inordinate length, or if the gaps in it are considerable, then its reluctance to magnetisation may be so great that very little magnetism will be induced in it, even by the application of considerable magnetising power. The principle of the magnetic circuit, about which much must presently be said, is of the first importance as a key to the behaviour of electro-magnets. A second guiding principle is to be found in the tendency which a magnetic circuit exhibits to perfect itself. That is to say, a magnetic circuit when subjected to a magnetic force tends, if so arranged that any part of it can move, to so alter its configuration as to become as compact as possible. If the armature, for example, is movable, and placed at some little distance away from the ends of the core or cores, it will be mechanically urged into greater proximity, so that core and armature may together constitute, as nearly as possible, a closed circuit of iron. In doing so the armature performs mechanical work. The action of the common horse-shoe form of electro-magnet in drawing up its armature, as in the ordinary sort of electric bell, is an elementary illustration of this principle.

A second form of electro-magnet consists of a tubular coil of copper wire into the hollow of which a long iron plunger is drawn when the electric current flows around the coil. This coil-and-plunger species of electro-magnet possesses several mechanical characteristics which distinguish it from the horse-shoe form; but the principle of the magnetic circuit applies equally to both.

*Modern Views of Magnetism.*

Now, in dealing with magnetic circuits we must carefully cut ourselves off from those medieval notions about magnetism which still haunt the text-books of physics, according to which magnetism is regarded as a sort of fluid (or fluids) distributed over the end-

Digitized by Google

surfaces (or poles) of magnets. With the polar distribution of supposed magnetic fluids we have nothing to do. The alleged fluids are pure fictions; the existence of a polar surface is a pure accident. The most highly magnetised part of a magnet is usually that part which shows upon its surface not a trace of polar action. The particular form of iron core which can be more highly magnetised than any other, namely, an iron ring closed upon itself, has no magnetic poles. Magnetism is, in truth, an internal rather than an external phenomenon. It is possible to have a steel ring so magnetised that the magnetisation shall be entirely internal; the magnetic lines flowing around wholly within the metal, and never coming up to the surface. Of course such a ring magnet is incapable of attracting iron filings or of perturbing a compass needle. The evidence that such a ring is magnetised internally is very simple. If cut or broken across, such a ring forthwith exhibits polar properties at the cut surface. A pole or polar region of a magnet is simply that part of the surface where the internal magnetic lines emerge into the air. Only such parts—the surfaces of gaps in the magnetic circuit—exhibit any such properties as those to which formerly the virtues of magnetic fluid were attributed.

The appropriate modern mode of regarding magnetic phenomena is to consider the various materials—iron, steel, air, and the rest—as being in various degrees *conductors of magnetic lines*, magnetic lines being stream-lines in the medium, conventionally taken to represent by their number and direction the quantity and direction of the flux of internal magnetisation. Soft annealed wrought iron is, for example, an excellent conductor of magnetic lines, being more permeable magnetically than any other known material. Magnetic permeability is a term to which a precise numerical notion has been attached, being the ratio between the magnetising force and the resulting intensity of magnetic induction in the specimen. This mode of regarding the matter has resulted from the modern study of electro-magnetic apparatus. The necessity of such ideas did not occur to the earlier workers in magnetism who were dealing exclusively with magnets made of steel or of loadstone permanently magnetised. They thought of poles acting from a point, as it were, attracting a piece of iron at a distance from it. We, on the other hand, have rather to think of stresses in the path of the magnetic lines. Wherever there is a gap in the magnetic circuit between iron and iron there is a magnetic stress urging the configuration so to change as to close up the gap. This stress urges the armature of the electro-magnet toward the iron core. You may call this an attraction of the one by the other if you prefer that way of putting it. Only beware, for this attraction does not vary as the inverse square of the distance between iron and iron; it depends solely upon the intensity of the magnetic flux in the intervening medium being proportional to the square of that intensity. The space crossed by magnetic stream lines wherein such magnetic stresses are in action is known as a magnetic *field*.

### *Invention and Development of the Electro-magnet.*

Immediately following the discoveries in 1820 and 1821 by Oersted, Ampère, and Arago of the magnetic properties of electric currents came, in 1825, the invention of the electro-magnet by William Sturgeon, of Woolwich. The apparatus he first produced consisted of a bent iron rod, about 1ft. long and ½in. in diameter, varnished over and then coiled with a single spiral of stout uncovered copper wire of 18 convolutions. For the first time there was thus put into the hands of the electrician a magnet capable not only of being excited and discharged at will, but of being operated from a relatively great distance by means of the electric wire. Sturgeon constructed numerous electro-magnets, some of the bent or horse-shoe pattern, others with straight bars or rods of iron as cores. In those days, copper wire overspun with silk or cotton was unknown as an article of commerce, and gutta-percha coverings were as yet undiscovered. Sturgeon was content to use uncovered copper wire of considerable thickness, wound in one layer only. To excite the power of electro-magnets furnished with so few convolutions of wire, it was necessary to work with relatively large electric currents; and to this end Sturgeon devised special forms of voltaic cell. Such currents cannot be conveyed to great distances through thin wires; hence the distance from which such primitive instruments can be operated is very limited. This objection was removed in 1828 by Prof. Henry, who discovered the great advantage to be gained in distant working by increasing the number of convolutions of wire. He employed copper wire from 25 to 40 mils in diameter, covered with silk, and coiled on in many successive layers. Shortly after Henry's modification of the apparatus to the purpose of efficient working at a distance through long lines of wire, Joule made further modifications for the purpose of obtaining the greatest adhesive or tractive power: the special forms of electro-magnet which he devised being distinguished by the compactness of their magnetic circuit. Other workers, such as Roberts, Radford, and Romershausen, followed in the track. In the United States Page applied the coil-and-plunger form to the construction of electro-magnetic engines. Telegraphic needs led to the production of forms of electro-magnet adapted to rapid working. Other forms specially intended to secure a greater range of action or greater uniformity of pull within the range were developed under the necessities arising from the application of the electro-magnet in the mechanism of electric arc lamps. Of all these various matters I have lately treated at some length in my Cantor Lectures before the Society of Arts.

### *Analogies between the Electro-magnet and the Steam Cylinder.*
